In the discussion which followed the reading of this paper Professor Reynolds said that the improvements made upon the Richards indicator in recent years were of great value, and they were now highly perfected; and that instrument still remained the one in most general use. With reference to the play in the joints after a little wear, this would produce in a diagram 3in. high comparatively little effect. If, however, the Richards was used for high speeds with smaller diagrams, the effect of the play would be very serious. A clear distinction should be made between high and low speed instruments, as the requirements were different in each case, and the same indicator would not act well under both conditions. For low speeds he preferred the Richards or the large Thompson, for high speeds the small Thompson or the Crosby. He did not agree that metallic pencils were better than graphite, and he preferred the latter. He had been particularly struck with the arguments in favour of double indication, and thought that the diagram obtained by the indicator shown might be found extremely useful if the difficulty of condensation and re-evaporation in the pipes could be overcome. He was not satisfied that this would be met by increasing the size of the pipes. The opinion was generally held that oscillations should not show themselves in the diagram at the commencement of the stroke, and too much pressure was put upon the pencil in consequence, but the result was that the friction set up had considerable effect upon the diagram.

Mr. E. G. Hiller said the parallel motion of the Tabor allowed an exact straight line to be obtained if the slot took the form of an ellipse, and the motion must therefore be more exact than the Thompson. At the same time the movement of the roller in the slot necessitated a certain amount of play. Referring to the various methods of adjusting the springs, he said that the only accurate one would consist in adjustment under direct steam pressure.

Mr. E. Worthington said that in indicating loco-

Digitized by Google

motives running at high speeds with the difficulties then existing, he thought metallic pencils much preferable to graphite. He had obtained good diagrams from locomotives with the Richards at speeds corresponding to 300 revolutions per minute.

Mr. Ingham, having worked with Mr. Kenyon in developing his indicator, said that they had experienced great difficulties owing to the continual variations of the indications. The atmospheric line was never twice in the same position, and the work as calculated continually varied. The great difficulty appeared to be that the pencil could not be made to describe a line proportional to the movement of the piston, as the free end of the tube described a circle or similar curve.

Mr. Foster preferred the method of attaching the lower end of the spring in the Crosby to that in the small Thompson, as the weight of the moving parts was less. He also thought the weight of the piston in the latter might be reduced, having, after long use, found no difficulty with the Crosby, in which the piston was much lighter.

Mr. Budenberg promised to make further investigations as to condensation in the pipes when the double indicator was used. A good deal could be said for and against both kinds of pencils, and he did not take any particular side in the matter. With reference to the indication of locomotives, the good results obtained by Mr. Worthington no doubt arose from the fact that the compression was very considerable. The difficulties with the Kenyon indicator could be explained by the effect of temperature on the tube, and perhaps the variations of the atmospheric line could be accounted for by the accumulation of condensed water in the tube which would weight the tube and alter its indications. He thought the effect upon the diagram of the weight of the lower boss in the small Thompson would be very small indeed.

Notices of Meetings.

NEXT WEEK.

THE INSTITUTION OF CIVIL ENGINEERS. Tuesday, February 18th, 8 p.m. Ordinary Meeting. Papers to be read: – "The Shanghai Water Works," by J. W. Hart, M.Inst.C.E.; "The Tytam Water Works, Hong Kong," by Jas. Orange, Assoc.M.Inst.C.E.; "The Construction of the Yokohama Water Works," by J. H. T. Turner, Assoc.M.Inst.C.E.

PHYSICAL SOCIETY.—Friday, February 21st, 5 p.m. Papers to be read:—"On a Carbon Deposit in a Blake Telephone Transmitter," by F. B. Hawes; "The Geometrical Construction of Direct-reading Scales for Reflecting Instruments," by A. P. Trotter, B.A.; "A Parallel Motion Suitable for Recording Instruments," by A. P. Trotter, B.A.; "On Bertrand's Refractometer," by Prof. S. P. Thompson.

ROYAL INSTITUTION OF GREAT BRITAIN. Friday, February 21st, 9 p.m. Shelford Bidwell, M.A., F.R.S., on "Magnetic Phenomena."

PRICES CURRENT, 12TH FEBRUARY, 1890.

Quotations at per ton, unless otherwise specified.

Messrs. Carrick & Brockbank, Manchester, report as follows:—

COPPER: The market continues flat, and prices lower. The present disorganisation of the pig iron market, and the continued high rate for money, have had a very depressing effect upon prices of other metals. It is now urged by some that the fall is justified by the slackened demand and the scarcity of orders offering, but consumers generally follow the lead of speculators, and any improvement in prices would, no doubt, bring in a large number of *bonâ-fide* orders, which have been held in abeyance. It is reported that the French holders of copper are maintaining a waiting attitude, believing that a recovery will take place shortly. Should the stock of copper, which is now in strong hands, be kept off the market, and a revival of demand spring up during the present month (which is not unusual after a quiet and dull January), there would soon be a steady improvement in the position of copper. At the moment Chili bars are very low, being quoted at £46 15s. to £47 5s. cash. Manufactured has been reduced £2 per ton, and is now quoted £64 sheets and £67 bottoms.

TIN has been depressed in sympathy with other metals. On the 5th quotations for foreign were £93 15s. to £94 2s. 6d. for cash, after which prices steadily declined to £90 5s. to £90 15s. yesterday. To-day an active market is reported at improved rates, viz., £91 to £91 10s.

LEAD has been exceptionally dull for the last few weeks. The arrivals from Spain and Australia during the past month have been considerably above the average, while the demand for consumption has been small.

SPELTER is weaker owing to the slack demand for galvanising and brass purposes. Some of the large consumers have resold their stocks of spelter, and this has forced down the price much below the actual position of the market. There is very little spelter in stock anywhere, and the consumption has for some time been unusually large, even without the galvanisers orders.

ANGLES, PLATES, BARS.

Messrs. S. W. Royse & Co., Manchester, report as follows:—

CHEMICALS.—During the past week matters have considerably improved in the alkali markets. Caustic soda has advanced very strongly, but is now stationary. Bleaching powder is in better demand at somewhat higher prices. Soda ash scarce. Soda crystals and bicarbonate of soda firm. Sulphate of ammonia continues to droop. Benzoles are easier. Carbolic acids unchanged. Creosote in rather short supply. Sulphate of copper is almost unobtainable on spot, but more freely offering for forward delivery.

FOREIGN TELEGRAPHIC ADVICES.

(From our own Correspondents.)

PARIS, Feb. 13.—*Iron.*—The market generally is without change. An uneasy feeling prevails, arising from the sharp relapse in England and the consequent check to business in Belgium. Prices remain firm, but buyers are holding aloof. The works in the Nord are now well supplied with coal. In the Haute-Marne the demand for wire continues unabated. In the Ardennes symptoms of weakness are appearing in the iron market.

Metals. The market for metals is inactive. Copper remains at last week's prices, but the demand for consumption is feeble. Tin continues its retrograde movement, having lost a point or two within the last few days. Lead is firmer, and has recovered a point. The demand for spelter is weak, and prices are quoted a little lower.

BERLIN, Feb. 13.—*Bourse.*—The fact that buyers are more numerous than sellers, and the momentary panics, which occur sometimes several times a day, show a want of confidence in the situation. Industrial securities have suffered severely. All classes have declined in value. Shares in colliery companies have receded considerably. Iron and steel works are weaker on the obviously false report that pig iron has become unsaleable.

Coal - The supply of Westphalian coal and coke for industrial purposes is insufficient to satisfy the demand. Washed smiths' nuts, 26s. to 28s. 6d.; foundry coke, 40s. 6d. to 42s. 6d.; blast furnace coke, 39s. 10d. to 41s. 6d. per ton delivered in Berlin.

Metals. – The tone of the metal market is somewhat weak. Though some concessions in prices have been made by sellers buyers manifest no disposition to operate beyond the needs of the moment. Copper is lower: Mansfeld refined, £60 to £61 10s.; English brands, £57 to £60. Tin has given way: Banca, £102 to £105. Lead is firm at last week's prices. Spelter is quoted a little lower. Ordinary Silesian, £25 15s. to £26. Antimony regulus has receded 20s.

BRESLAU, Feb. 13.—*Coal.*—The demand for coal is falling off, so that the railways can now cope with the trade. The shrinkage is due to a slackening demand for house coal, a consequence of the mild winter, and to the completion of the extra storing which has of late being going on at the railway depôts in view of another strike of colliers.

Iron —The demand for pig iron being still in excess of the production our market remains unaffected by the relapse which has occurred in some of the foreign markets. Cast iron scrap is much sought after at 90s. a ton for good quality. Finished iron and steel is in strong demand, all classes being inquired after. Business brisk in wire and wire nails. Prices generally above syndicate minimum. Engineers and machine makers report increasing activity.

Metals.—The market is steady for zinc. Spelter is firm at last week's prices. Manufacturers, being sold several months forward, are not disposed to seek fresh orders by offering concessions in price. Lead is very firm, stocks in hand being practically nil.

DUSSELDORF, Feb. 13.—*Coal.*—The advance of from 1s. to 2s. a ton which has occurred within the last few days is willingly paid. Export orders to Belgium are being refused. Everybody is stocking, in anticipation of the threatened strike of colliers. The attitude of the latter is disquieting.

Iron.—The market for pig iron is quieter. Buyers are few and transactions unimportant. Prices remain firm, however, and have even slightly advanced for Thomas pig. For finished iron and steel of all classes except wire the market is active. But wire and wire nails have advanced in price from 10s. to 15s. a ton, to cover the increased cost of the raw materials. Rolled wire, 195s.; wire nails, 220s. a ton

STETTIN, Feb. 13.—*Iron.*—The relapse in the English and Scotch markets has been hitherto without influence on the market here. Quotations remain: English No. 3, 90s.; Scotch, 100s. to 105s.; German bar iron, 215s.; and common plates, 250s. to 280s. a ton.

CHARLEROI, Feb. 13.—*Iron.*—The relapse in the English iron markets has alarmed buyers here, and business is very slack in consequence. Sellers, however, maintain their prices. Some manufacturers quote above the syndicate minimum. The Couillet and the Acoz companies have divided between them the contracts for 40,000 iron sleepers (about 1,300 tons) for the Congo railway. The price is 189s. 6d.

HOME INDUSTRIES.

LONDON 13th February, 1890.

The Money Market.—The hold of the Bank of England on the money market having slackened a little through the course of events bringing more money under command of outside lenders, there has been an easing of the tension which has existed for some weeks. The Stock Exchange readily felt the effects of this during the settlement this week. In the first place, the quantity of stock to be carried into the new account was comparatively small, and the rates charged for loans to continue transactions became lighter. This gave a distinct impetus to speculative activity, the first securities to respond being those of the British railways. The opening of the new account was signalised by a rebound in nearly all these stocks, good returns from the Brighton line, a favourite barometer of this department, giving the keynote to the market. The American railway market has been neglected, and Canadian railways, though rather more in favour, have not been prominent. The Mexican Railway having failed to maintain its good traffic returns, its securities have receded again. Foreign stocks have not been greatly in evidence. Egyptians and Brazilians have risen slightly, but the publication of the terms of the new loan was followed by a drop in Russians. Mining stocks still lack favour, copper shares falling with the metal market, and gold shares have few friends. Nitrate securities fail to rally, and among the features of the week was a sharp trouble in brewery shares.

Companies.—The following companies have been registered since our last report:—The Cardonnel Tin-Plate Co., Ld., with a capital of £20,000; W. & H. Foster, Ld., with a capital of £350,000, to take over the business of Messrs. W. & H. Foster, worsted spinners, &c., Bradford; The Belmez Coal Co., Ld., with a capital of £140,000, to acquire certain coal mines in Spain; The Standard Rubber Stamp Manufacturing Co., Ld., with a capital of £1,000; The Borneo (Sambas) Exploration Co., Ld., with a capital of £100,000; The Princesa Gold Mining Co., Ld., with a capital of £125,000, to acquire certain claims in Mexico; The Colonial Manganese Co., Ld., with a capital of £8,000, to work manganese and other minerals in New Zealand; The Windsor Reef, Ld., to carry on mining operations in South Africa; The Kondaho Petroleum Syndicate, Ld., with a capital of £35,000; The Monte Video Tramways Co., Ld., with a capital of £100,000; The Ludrig Coal and Ore-Dressing Appliances, Ld., with a capital of £200,000, to acquire the business of the Ore Machinery Co., makers of mining machinery, &c.; The Port Talbot Tin-Plate Co., Ld., with a capital of £35,000; Hutton's Brewery, Ld., with a capital of £100,000, to acquire the business of R B. Hutton, North Saltley; The Elkhorn Mining Co., Ld., with a capital of £200,000; The Mutual Telephone Co., Ld., with a capital of £100,000; The United States Metallic Packing Co, Ld., with a capital of £15,000; The Somersetshire Manganese and Iron Ore Co., Ld., with a capital of £25,000; The Embossing and Sand Blast Printing Co., Ld., with a capital of £2,500; R. & T. Clayton, Ld., with a capital of £10,000, to acquire any mill for spinning and weaving cotton; Trent Gas Engine Co., Ld., with a capital of £15,000, to acquire certain patents; The Mount McClellan Mining Co., Ld., with a capital of £300,000, to carry on mining operations in Colorado.

The Board of Trade Returns.—The January returns give no ground for complaint, and though the imports show no very great expansion, the increase in the value of the exports is exceedingly satisfactory. The value of the month's exports was £21,586,752, as compared with £20,527,037 in the same month of 1889, being an increase of £1,059,715. The Eastern markets have been unsatisfactory for textile goods, and the exports of yarns and textile fabrics consequently show a decline, having fallen from £9,970,972 to £9,853,489. Metals and articles manufactured therefrom (except machinery) have advanced from £3,056,923 to £3,577,155, this being largely due to higher prices. Machinery and mill work, which amounted to £1,112,981 in January 1889, were £1,352,223 this January, while chemicals rose from £658,719 to £689,818. The imports amounted to £38,143,850, as compared with £38,058,318, being an increase of £85,532. There are decreases under various heads, and the total would have shown a falling off had it not been for the large advance in the imports of wool.

The Navy.—A serious accident happened on board the "Barracouta" during her trial trip last Friday. It will be remembered that, a week or two ago, the trial trip of this vessel had to be postponed on account of a defect in the engine cylinders. On the trip under natural draught last Friday all went well until suddenly the draught in the furnace was reversed, and the flames and smoke burst out through the door of the furnace and entered the stokehold. One man was killed and all the other occupants of the hold were seriously injured. An inquiry as to the cause of the accident is now being held. It may be mentioned that after this accident the vessel steamed back to port under half-steam pressure without any recurrence of the mishap.

Institute of Marine Engineers.—A meeting of the Institute of Marine Engineers was held in the Langthorne Rooms, Stratford, E., on the 31st ult., when a paper on "Ventilation and Heat Radiation," by Mr. A. Sommerville, was read. The paper dealt with the prevailing condition of things as regards the ventilation of steamers, the inadequate means provided for lessening the amount of heat radiating from all parts of the machinery, and the results which followed directly and indirectly. The elementary principle on which ventilation is based was shortly touched upon, and the difficulties in the way of applying a perfect system to the various styles of buildings, and the still greater obstacles in the way of applying such to the engine-room and stokehold, were referred to. The difficulties experienced by engineers and the responsibilities resting upon them in the discharge of their duties in the more modern steamers were also remarked upon.

The Royal Laboratory, Woolwich.—Mr. H. T. Ashton, M.Sc., Victoria University, has been appointed by the Secretary of State for War as assistant engineer in the Royal Laboratory, Woolwich. Mr. Ashton was educated at Owens College, Manchester, where he gained the Certificate in Engineering, and has since been employed in the works of Messrs. Wm. & Jno. Yates, engineers, Blackburn.

MANCHESTER, 13th February, 1890.

The Manchester Ship Canal.—The Consultative Committee completed their visit to the ship canal works a few days ago. They found the work in a very advanced condition in many sections. At the Eastham end great progress has been made with the entrance locks, and both there and at Latchford and Barton the large lock gates are in course of construction. The railway diversions are rapidly approaching completion, and generally the work is well ahead of time.

The Iron Trade.—Trade has somewhat improved owing to the better state of things in the Glasgow market. It is thought that the weakest point has been passed, and that the clearing out of several speculators which has taken place will steady the market again. Buyers are on the alert to secure a favourable market, and as there is a little give in quotations additional business has been negotiated. There is a general confidence in an advance, as the statistical position, in spite of the abnormal state of things since the beginning of the year, has strengthened and not weakened. It is known that a number of large works are likely to be carried out shortly, and a large accession of shipbuilding orders is looked for. Under these circumstances the news in this market is rather hopeful than otherwise. An addition to the metallurgical industries of this neighbourhood is about to be made. It is intended to commence works for the manufacture of all kinds of steel castings by the methods patented by Mr. J. E. Bott. The board of directors is a strong one financially, and in this respect the new company will stand well.

Warp Balling Machine.—Mr. J. H. Stott, of Rochdale, has just perfected a machine for making warp balls which will be of interest to all manufacturers. Instead of forming the ball by winding it on a mandril kept in frictional contact with a revolving drum, he uses a vertical mandril in a swing cradle, to which an oscillating motion is given. Surrounding the mandril is a light iron ring or flyer running freely on anti-friction bowls and driven by frictional contact with a bowl. By an ingenious arrangement the warp is guided to the guide roller on the flyer by two rollers, one carried on the centre spindle of an arm and the other at its end. In this way any variation in the tension of the warp causes the arm to oscillate slightly and turn the shaft on which it is fixed. Fastened on the latter is an arm or cradle carrying the friction bowl. In this way the velocity of the flyer is regulated in exact accord with the tension of the warp, and the traverse of the latter accelerated or diminished. This is one of the chief features of the machine, and another novelty is that the ball is formed directly from the creel. This saves a good deal of labour and space, and in this respect the machine is noteworthy. A marking apparatus is fitted by which the cuts can be marked as desired. The machine is a great advance on any of the kind previously made.

The Linen and Jute Trades.—There is a decidedly increased feeling of confidence in home trade circles, less grumbling being heard as to the condition of business, while reports of greater activity are frequent. The new year's samples have brought in good orders, and mills are fully engaged, the only discouraging feature being in connection with the heightened cost of production, which in the case of a Northumberland concern has been so heavy that an application for provisional liquidation in Chancery has been made. Fuel is much too dear considering the price at which linens are now being sold by manufacturers. A new factory for the weaving of damasks is about to be erected in Kirkcaldy, a fact which indicates the activity prevailing in certain sections of the trade at the present time. Fancy jute goods, such as Brussels carpets, are moving off well, and there is an average business for the season passing in jute mattings. Linen threads are unaltered, but satisfactory quantities continue to be purchased by the large ready-made clothing manufacturers at Hebden Bridge, Leeds, and elsewhere. Prices are on a level with those current at the commencement of 1888.

GLASGOW, 13th February, 1890.

Shipbuilding.—There is a report that Messrs. A. & J. Ingles, Pointhouse, Glasgow, have secured an order for a 5,000 ton steamship for the British India Company. A four-masted steel ship, of 2,300 tons, has been ordered from Messrs. Duncan & Co., Port Glasgow, by Messrs. Gibson & Clark, Waterloo Street, Glasgow. The vessel is to be ready in June. A fire took place on Monday evening in the shipyard of Messrs. Robert Duncan & Co., Port Glasgow. The joiners' shop, a building of 350ft. in length, was completely destroyed, and damage effected to the extent of £10,000.

Pig Iron.—The "clearing out" process that has been going on for some time past in the iron market culminated on Monday morning, when, under the influence of one or two small failures and the apprehension of more to follow, sales of Scotch warrants were made at the opening of the market at 51s. 6d. to 51s. 1½d. cash, but gradually it was felt that the selling was pretty well exhausted, and that the bulk of the iron had passed into strong hands, while legitimate demand was coming on at the lower range of prices that had been established; and when Monday's very heavy settlements had passed off safely, confidence seemed restored, and sellers had no further cause to throw away their iron. There was a quick recovery on Tuesday, Scotch going to 53s. 6d cash. At that point there was a little reaction, but afterwards the market became steady.

Engineering.—General engineering is still in a very brisk state. Orders are every week being refused by firms whose resources are not equal to the output demanded.

The Forth Bridge.—The arrangements for the opening of the Forth Bridge by the Prince of Wales on the 4th March have now been finally settled. Instead of staying at the New Club, Edinburgh, the Prince is to stay with the Earl of Rosebery at Dalmeny. The directors' train will leave Edinburgh (Waverley Station) about eleven o'clock, and the Prince of Wales and party will join the train at Dalmeny Station. The train will then cross the bridge and proceed to Inverkeithing, as formerly provisionally arranged. On returning to North Queensferry, the party will embark on board two steamers, and, after being afforded an opportunity of seeing the bridge from the Firth—a proceeding whose enjoyment will depend entirely upon the state of the weather—will rejoin the train and cross the bridge to South Queensferry. At the connecting girder on the south side the train will stop, and the last rivet will be driven by the Prince. A banquet will be given by the directors at South Queensferry after the ceremony. Proposals are on foot to have a public holiday in some of the large towns in Scotland on the 4th March.

The Edinburgh Electrical Exhibition.—A singular proposal has been made in connection with the Electrical Exhibition to be held in Edinburgh this summer. This is to erect in the grounds of the Exhibition a model of the Forth Bridge, on the scale of ½in. to the foot. The model would thus be 300ft. long, and the headway under the centre of the spans would be 12ft. It is said that the Edison-Swan Company are willing to fit up such a model with 5,000 incandescent lamps. A deputation from the executive of the Exhibition waited on the directors of the Forth Bridge Railway Company with reference to the matter, but no decision has yet been arrived at.

The Gold Extracting Companies.—The Cassel Gold Extracting Company has just resolved to increase its capital by the issue of 30,000 new £1 shares. This makes the total capital of the company £180,000. The Australasian Gold Extracting Company (Pollok's Patents), Limited, has just been formed. Shares to the amount of £100,000 are to be taken as part payment by the parent company (Pollok's Patents Company), and the remainder of the capital (£150,000) was offered to the public for subscription. Applications were lodged for £190,476, or about 25 per cent. more than was asked for.

(From our own Correspondents.)

LIVERPOOL, 12th February, 1890.

The West Lancashire Railway Company.—In the half-yearly report of the directors, just issued, it is stated that the gross revenue for the half-year was £11,539 19s. 7d., as against £11,178 9s. 11d. of the corresponding period last year. The expenditure has been £10,429, showing a profit of £1,110. Considerable progress is being made with the Blackpool Railway, which will form an important branch of the West Lancashire line, and most of the land has been acquired for the undertaking.

Floating of the S.S. "Ligurian."—An interesting marine operation has just been performed on the River Mersey. On the 30th November last the "Ligurian," laden with Egyptian cotton, was run down while entering the dock by the steamer "Iowa," and literally cut in two, but kept afloat sufficiently long to be beached at Egremont. The stern half was towed to Messrs. Clover's shipyard, the watertight bulkhead preventing it from foundering; the other half will be towed from Egremont in a similar manner, and the two pieces joined together. A similar accident happened to the "Tudor," which was successfully floated and repaired in a similar manner last month, and now sails under the name of the "City of Belfast."

New Boats for Woodside Ferry.—The Birkenhead Town Council have just given Messrs John Jones & Sons, of Liverpool, an order for the building of two new double twin-screw passenger steamers, at a cost of £25,800. The boats are to carry 600 passengers, at a minimum speed of 12 knots an hour.

LEEDS, 12th February, 1890.

The Iron and Steel Trades.—Business has been somewhat restricted in the past fortnight, in consequence of the speculative condition of the iron market. Though

Digitized by Google

inquiries are far less numerous than they were a month ago, there does not appear to be great eagerness on the part of manufacturers to sell, the chief reason for this being that the orders booked are ample for months to come. On the other hand, it is said that in some quarters the recent falling off in the demand for raw material is provoking fears as to the future. The unsettled state of the market has told against the inquiries for finished iron and steel from the Colonies and Australia. Prices obtained a fortnight ago are still adhered to with few exceptions, and with the contracts entered into the bulk of the finished iron makers and steel manufacturers are in a position to wait future developments. The engineering trade is still marked by great activity. There is hardly a firm which is not working full time, and several of the principal shops have work for fully six months ahead. One or two minor trade disputes are pending. Leeds boilermakers have served their employers with notices for an advance of 2s. per head all round.

THE COAL TRADE.—The West Yorkshire Coalowners' Association was represented at the meeting of colliery proprietors which was held in London on the 10th to consider the proposed formation of a colliery proprietors' federation and the demand of the colliers for a 10 per cent. advance in wages. The decision of the coalowners to resist the demand has created no surprise in the trading circles of this district. There is no doubt in the reality of a falling market with regard to house coal, both in price and demand, and indications are not wanting of a smaller inquiry for coke. Steam coal continues to be much sought after. As to the position of the colliery owners, it is hardly disputed that the contracts entered into have not been so remunerative as was anticipated, owing to the rapid advance in the cost of labour and materials.

SHEFFIELD, 12TH FEBRUARY, 1890.

RAILWAYS.—The first sod of a new local line of great importance was turned on Friday last by Earl Manvers. The main line from Beighton Junction to Chesterfield is 10¾ miles, and from Staveley to the junction with the Great Northern Railway at Annesley is 16¼ miles, making a total of 27¼ miles. This line will tap a coalfield estimated to contain 800,000,000 tons of coal. The present annual output of the collieries served by the new line is 17,000,000 tons.

COAL.—The colliery owners of South Yorkshire held a meeting on Tuesday, at Sheffield, to consider the question of miners' wages. There was a large attendance, most of the principal owners in the district being represented. The tone of the meeting was decidedly against any advance being conceded. No less than 35,000 men are concerned in this agitation.

IRON AND STEEL. The directors of Messrs. Vickers, Sons, & Co., Limited, have intimated to the shareholders that a further dividend for the year 1889 will be distributed shortly. Messrs. Henry Bessemer & Co., Limited, have issued a very satisfactory account for the past year's work, which is their first year as a limited company. A profit of £37,138 has been made. Several other local companies also announce substantial dividends. Pig iron has fallen from 10s. to 15s. per ton, and no doubt a corresponding reduction will be made in merchant and bar iron. The most serious item in the production of iron at present is the high price and scarcity of coke.

NORTH STAFFORDSHIRE, 12TH FEBRUARY, 1890.

THE IRON TRADE.—There is no complaint amongst the finished iron makers of the district with regard to orders or specifications this week. Prices are perhaps slightly weaker, bars selling at about £8 15s. to £9 per ton. Pig iron is in good demand, and prices show no signs of weakness. Middlesbrough iron is being brought into the district, and can be bought at lower prices than those ruling for local brands.

THE COAL TRADE.—The cold weather of the last few days has given a spurt to the sale of fuel for domestic consumption, and prices, which were showing signs of weakness, have hardened again.

DERBY, 12TH FEBRUARY, 1890.

THE MIDLAND RAILWAY.—The Company are seeking powers to raise £1,500,000 additional capital for the construction of branch lines in this district and other purposes. It is stated that an offer of £110,000 has been made for the whole site of the St. Pancras workhouse, which adjoins the Company's premises, with a view to an extension of their accommodation in North London. So great has the crush of goods traffic been of late that the directors have found it desirable to cut down permanently the number of passenger expresses in order to make way for luggage trains. The decision of the Board to sacrifice half-empty passenger for well-filled goods trains derives justification from a comparison of the passenger and goods traffic on this line. The goods receipts for the last half-year amount to £2,869,000 in a total of £4,221,000, or 65 per cent. of the whole, as against 57 per cent. in the case of the London and North-Western and 58 per cent. in that of the Great Northern Railway. Since 1881 the Company have expended more than a million and a half in buying up the coal waggons formerly owned by private traders, a policy that it is believed has greatly facilitated operations in the mineral department. An important change has been made with through goods trains between Bristol, Derby, and Scotland, some 24 of which will cease to pass *vid* Normanton, and will be worked *viâ* Pontefract over the Midland and North Eastern lines, effecting a considerable saving of time. The directors have recommended a dividend of 6¾ per cent. per annum for the last half-year.

COAL AND IRON.—Slack for steam purposes and coke are in good request, but the mildness of the season has caused a falling off in the demand for house coal. The whole of the capital for the Bolsover Colliery Company, Limited, has been subscribed, and it is announced that the plant for the colliery has been ordered. The coal, which is known as the "top hard coal," will be worked at a depth of between 300 yards and 400 yards. The Kilbourne Colliery has been re-started, with a capital of £20,000. The Erewash Valley Ironworks at Ilkeston have lighted their No. 1 furnace, which has been idle during the last six years. It has a producing capacity of about 400 tons of pig iron per week. The other furnaces of the company are undergoing repairs, and it is hoped that they also will shortly be in blast.

THE GAS WORKS.—The Derby Gas Company seek powers to raise £200,000 for extensions, which the Corporation, who themselves are promoting an application to the Board of Trade for supplying the electric light to the borough, will oppose.

CARDIFF, FEBRUARY 12TH, 1890.

COAL AND COKE.—The steam coal market continues exceedingly active, and buyers are quite at the mercy of colliery owners. One strange feature in the position is that inferior coals have advanced to a greater value proportionately than first-class qualities. Prices of large steam coal f.o.b. Cardiff are as follows: First quality, 15s. 9d. to 16s. 3d.; second, 15s. 3d. to 15s. 6d.; third, 14s. 9d. to 15s. Tonnage is plentiful, and, as freights outwards for the Mediterranean keep low, contractors are shipping as much as possible in view of a probable advance in freights. The coke market is not quite so active, but as all sellers are fully sold prices for odd parcels show no sign of weakness.

IRON AND STEEL.—In the pig iron trade the drop in Scotch warrants has completely suspended business. Makers, however, are firm in their prices, in view of the high prices for coal, coke, and iron ore, and, with the workmen's demands, it is difficult to see how they can give way. The trade cannot long remain as it is, and the general opinion seems to be that the legitimate trade is really no worse than when warrants were 12s. to 13s. higher than they are now. The same applies to steel, and for steel bars makers are firm at £7 15s.

IRON ORE.—Prices for Rubio ore are 17s. c.i.f. Cardiff or Newport, 18s. Middlesbrough, 18s. 3d. Glasgow. Sellers will not make any reduction on this price, and, as ironmasters are fairly well bought, the business transacted has been of a very limited nature.

MIDDLESBROUGH, 12TH FEBRUARY, 1890.

PIG IRON.—After the discouraging collapse of prices in the pig iron market, it is pleasant to have to report a reaction. Yesterday, there was not only a more numerous attendance on 'Change, but there was a greater eagerness to buy. Prices had fallen to 52s. 6d. for No. 3 G.M.B. prompt delivery. The market opened with this price, but it soon rose to 53s. and 53s. 6d., where it now stands. This was mainly owing to the favourable telegrams from Glasgow, where the chief business in Cleveland warrants is now carried on. Makers have never given in to the lower prices, but hold out for 60s. Those in want of iron take warrants in preference. Makers are confident of better prices shortly, and hold on at their own price. In hematite East Coast brands are quoted nominally at 78s. per ton f.o.b. for Nos. 1, 2, and 3 makers' iron. The stock in Connal's store yesterday amounted to 182,523 tons as against 184,227 tons a week ago, showing a decrease of 1,704 tons over the week.

SHIPMENTS OF PIG IRON.—The shipments have rallied considerably, and contrast more favourably with those of last month and the same month last year. Up to the 10th of the current month they amounted to 18,351 tons, against 15,380 tons to the 10th of January, and 14,507 tons to the 10th of February, 1889. Scotland is again taking her share, as also are Germany and Holland. There are signs, in fact, of a revival of the demand for pig iron both at home and abroad, and makers seem to be warranted in their expectations of higher prices in the immediate future.

MANUFACTURED IRON AND STEEL.—The demand for forge pig iron keeps it still 3s. or 4s. in advance of No. 3, so that, though the latter is 53s. 6d. per ton, the former cannot be had under 57s. per ton. This shows the steady pull on it by the wrought iron manufacture. Although there is little doing in the way of new orders, those in hand keep up the demand. Prices, however, are weaker in some lines. Iron ship plates are at £7 10s.; ship angles, £7 5s.; common bars, £7 10s. per ton, less the usual discount, f.o.t. on trucks at manufacturers' works. Steel ship plates are at £8 10s.; ship angles, £8 5s.; rails, £6 12s. 6d. per ton f.o.t. on trucks.

SUNDERLAND, 12TH FEBRUARY, 1890.

SHIPBUILDING AND MARINE ENGINEERING.—The dearth of new orders continues, and the demands for increased wages on the part of workmen have not ceased. The fitters and other members of the Amalgamated Society of Engineers have been temporarily quieted by being granted 1s. per week increase, with the understanding that a further similar increase, and reduction of working hours on Saturdays, shall be considered at an early date. Messrs. Wm. Allan & Co., of the Scotia Engine Works, are not bound by the decision, as they are not in the employers' association. This firm state that they cannot grant any increase, but in April or May they will perhaps be able to arrange to cease working on Saturdays at 12 a.m. instead of 1 p.m., as desired by the workmen.

SHIPPING.—Outward freights, despite fluctuations, have improved, but homeward prompt business from the Black Sea and Mediterranean is not satisfactory, and owners find great difficulty in obtaining remunerative freights. In the American market, which has so far been very firm and promising, forward fixing threatens to cause a collapse. The local coal shipments are still far from satisfactory, owing to the deficient outputs of the collieries.

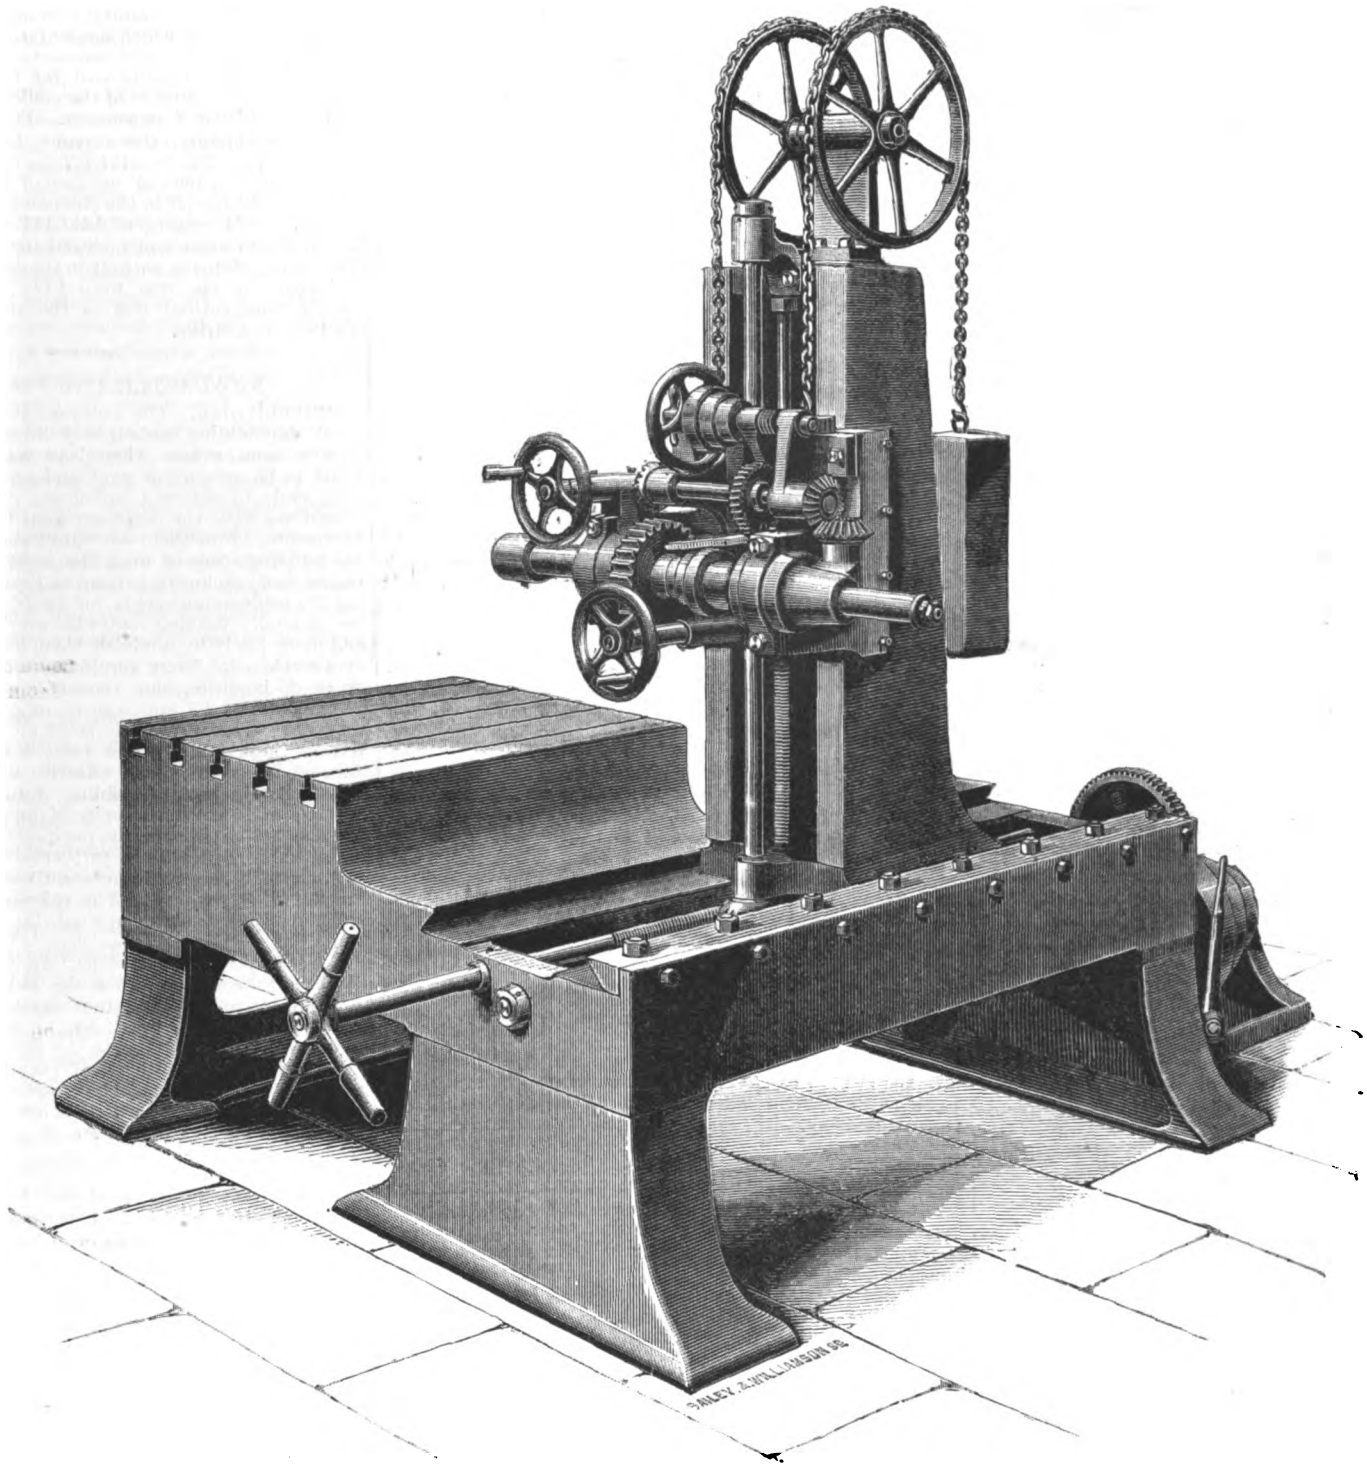
RIVER WEAR COMMISSION.—The annual returns are fairly satisfactory, the revenue having increased from £131,864 12s. 2d. to £134,437 2s. 2d. for the year ending December 31st, 1889, an increase of £2,572 10s. This is in spite of a falling off in the clearances and in the coal shipments. 6,824 vessels, of 2,531,174 tons, were cleared, as against 6,997 vessels, of 2,539,502 tons, in the previous year, the falling off being entirely in the coasting trade. The coal shipments of the year were 4,122,509 tons, a decrease of 68,217 tons, entirely due to the stoppage of Silksworth Colliery by a strike.

NEWCASTLE, 12TH FEBRUARY, 1890.

SHIPBUILDING.—The outlook at the moment in the local shipbuilding trade is very different from what it was twelve months ago, when there was scarcely an empty berth to be seen on the river, and employers were at their wits' ends to secure a sufficiency of labour to carry on operations with the necessary despatch in the various departments. Now there are vacant places to be observed in the building space of even the most important establishments, and employers, instead of having to keep importuning the trade union agents for fresh supplies of workmen, are, generally speaking, somewhat overburdened with labour, and more likely to diminish than increase the number of men employed. There continues to be a very marked absence of inquiries, and scarcely any new contracts are being placed. All appearances, indeed, point to the conclusion that, what with the large production of last year and the high prices of the present, the demand for new tonnage has received an effective check, and the present activity in the building yards cannot therefore be long maintained. In spite of the very palpable change that has taken place in the prospects of the industry, the workmen are agitating for further advances of wages, and an important section have recently sent in a claim for an increase of 3s. per week. The splendid steamer "Eagle," which has just been completed by Messrs. Hawthorn, Leslie, & Co., for a Russian firm, is to take her trial trip this week, prior to her departure from the port. The vessel is expected to prove the swiftest as well as the largest merchant steamer that has yet been built on the river, and, from the great care that has been bestowed on her construction, there can be no doubt that in other respects also she is quite an exceptional vessel. At other yards on the river the finishing touches are being put to a considerable number of vessels, some of which are being fitted up for the accommodation of passengers.

ENGINEERING. The wages question in the local engineering trade has been settled by the concession of 1s. per week advance by the employers, but it is understood that the question as to the 12 o'clock stopping time on Saturdays will be raised again at the end of the month. Messrs. R. Stephenson & Co., of the South Street Works, have just commenced the construction of the largest set of triple expansion engines yet built by them. They are intended for a vessel to be built at the firm's yard at Hebburn. The locomotive department is extremely busy, the firm having engines in hand for home and foreign railway companies. At Messrs. Watson & Son's establishment, High Bridge, business continues active, the demand for the special ships' pumps manufactured by the firm being particularly good.

THE COAL TRADE.—The coalowners, at a meeting held on Saturday, decided to refuse the advance asked for by the Northumberland miners, but indicated their willingness to reconsider the matter when the ascertainment of prices is taken for the months of December, January, and February. The shipments of coal and coke at Tyne Dock for the week ending February 8th amounted to 111,053 tons, being an increase of 23,767 tons as compared with the shipments for the corresponding week last year.



DUNDEE, 12TH FEBRUARY, 1890.

JUTE AND FLAX TRADES.—Advices from Calcutta state that the market for loose and baled jute is showing a downward tendency. In this market there is at present comparatively little doing, either in spot parcels or on contract. Jute yarns are in better request and prices have improved. The demand for Hessians is also brisker, and advices from New York report a firmer market there this week. Burlaps 40in. 10½oz. are quoted at 5¼c. to 5⅜c. per yard, compared with 5⅜c. to 5½c. last week A decline in the rates asked for flax has led to an increase in business, and a considerable number of contract transactions are reported. Complaint continues to be made of the influence exercised by foreign yarns in depressing home yarns. For linen cloth orders are coming in satisfactorily. In the fine goods produced in the Fifeshire district the demand on home account is not coming up to expectation. Orders for export are satisfactory, and manufacturers are well employed.

HORIZONTAL DRILLING AND BORING MACHINE.

CONSTRUCTED BY MESSRS. HETHERINGTON & CO., ENGINEERS, MANCHESTER.

HORIZONTAL DRILLING AND BORING MACHINE.

WE illustrate above a useful horizontal drilling machine designed for a variety of work where it is difficult to fix the article to be drilled. It has a massive bed, formed with a transverse slide, in which the vertical standard is fitted. The latter is of strong design, and has a carriage or headstock fitted to a vertical slide on the face of the standard. The wearing surfaces in both the transverse and vertical slides are broad, giving great rigidity. The boring spindle is borne by the carriage in hardened necks, and has a variable self-acting feed by means of a rack and pinion, which can be readily disengaged so as to give a hand feed. The illustration will show that the machine is powerfully geared in the carriage, and that a stepped cone is fixed on the driving shaft, two changes of gear being also added. If necessary, a reversing motion can be fitted for tapping, the carriage being balanced as shown. The illustration represents a machine with a table 3ft. by 2ft. 6in., a horizontal traverse of 3ft., the spindle having a vertical movement of 2ft. and a self-acting feed of 12in. Messrs. Hetherington & Co., of Manchester, are the makers.

COMMERCIAL EDUCATION.

THE Conference which was held in London recently, under the auspices of the London Chamber of Commerce, and with the Lord Mayor in the chair, marked an important step in the advancement of that department of technical education which is of special use to those engaged in commerce. We have often pointed out that, if employers would only take a little more interest in the subject, the problem of technical education could easily be solved. If they encouraged, or if necessary, insisted on their young men supplementing their experience in the workshop, manufactory, or office by classes in which they obtained a knowledge of the theory of their work, their requirements would be fully met without any very elaborate organisation. The object of the Conference was chiefly for the purpose of bringing about co-operation between teachers and employers, both of whom were represented by leading men.

The Lord Mayor pointed out that commercial education was becoming at the present day a question of bread and butter, and further, that the competition of foreign clerks with those of our own country was increasing rather than diminishing. The scheme which had been arranged by the London Chamber of Commerce had been revised by a special committee and by the Oxford and Cambridge Examining Board, and had thus been brought into conformity with the wishes of men of business and of educationists, and it had been prepared so as to be adaptable to commercial and industrial centres throughout the kingdom. The London Chamber only undertook examinations and management of the scheme in regard to the Metropolis, and it was hoped that similar arrangements would be made for other large centres. The scheme sought to supply inducements to schoolmasters and pupils, such as hitherto had not existed in this country, but which had long been in action in France and Germany under the military system, as in those countries young men passing their school examinations were able to complete their military obligations with one year's service, whereas they were obliged to serve three years if they failed in their examinations. The London Chamber of Commerce had succeeded in obtaining the co-operation of over 200 firms in the City, who agreed to give preference in employment to young men who had taken certificates under the scheme. It had also obtained from its members offers of various prizes and scholarships to be given for the highest passes under the scheme, or for passing in particular subjects.

Another object of the Conference was to make the scheme widely known, in order that it might be taken up in as large a number of other towns as possible.

Advertisements intended for insertion in the current week's issue should reach our London Offices not later than first mail delivery on Thursday morning. Scale of charges for displayed advertisements on cover and inside pages will be forwarded on application. Orders for single advertisements must be accompanied by payment in order to ensure insertion, the charge for which is 2s. 6d. for the first four lines or under, and 8d. for each additional line. Situation advertisements (Vacant or Wanted) 1s. for two lines or under, and 6d. for each additional line—which averages eight words. While all practical regularity in the insertion of serial advertisements will be observed, it can only be absolutely guaranteed in the case of those ordered to appear weekly.

As we go to press early with certain of our advertisement pages, all Alterations to Standing Advertisements should reach the Publisher not later than 2 o'clock on Wednesday afternoon in each week.

All accounts are payable to GEO. CAWLEY, 358, *Strand, London, W.C. Cheques should be crossed Manchester and Liverpool District Banking Co., Limited, 75, Cornhill, London, E.C. Post Office Orders should be made payable at the Post Office, 369, Strand, London, W.C.*

Industries:

FRIDAY, 14TH FEBRUARY, 1890.

THE GERMAN EMPEROR AND THE LABOUR QUESTION.

THE rescript of the German Emperor gives a fresh turn to the discussion upon the labour question. It does not yet appear whether he has been inspired by the State Socialism of Bismarck, or by the professorial Socialists in the chairs of political economy in Berlin and elsewhere, or whether his manifesto is simply an astute political move to outdo the Social-Democrats and thus to cut the ground from under the feet of the rapidly growing Social-Democratic party in Germany. The most favourable view of the action of the Emperor William is that he has set before himself the enormous task of settling the wages question, not only for Germany, but for the civilised world. If he has really set himself to do this, we can at least admire the gallantry of the attempt, however little faith we may have in the success of it. If the not unnatural suspicion is well founded, that political expediency, and not enthusiasm of humanity, has produced the manifesto, the Social-Democratic, or rather the Radical, party in Germany may be trusted to discredit it. In the meantime, we are bound to take the manifesto seriously, and to ask ourselves what it really means and what its probable results may be. As might be expected from a Government which is even yet largely despotic, the indication which the Emperor William gives of his theory of the State is practically that of a State in which the dominant power is the King, who is the father of his people. "It is the duty of the State," he says, for example, "so to regulate the duration and nature of labour as to ensure the health, morality, and economic wants of the working men, and to preserve their claim to legal equality." This theory is certainly not that generally current in England and in America. In both countries, in spite of an intermittent and frequently unobserved tendency in the actual practice of legislation to increase the power of the State, the general tendency of public opinion is that that power should be curtailed rather than extended. In so far as the Anglo-Saxon people may be taken as a gauge of progress, and their tendencies assumed to be in the line of it, the conclusion would be that the Emperor William's opinions and proposals are alike reactionary. We were at that stage long ago. The writings of English statesmen in the reign of Queen Elizabeth exhibit many passages parallel to that we have quoted from the speech of the Emperor William; but we have progressed a great deal since then. In fact, our theory of the State has pretty well been reversed. Instead of regarding the State as being bound "to regulate the morals and the economic wants" of men, we now-a-days look upon it as being a rather greedy monster, who devours a large portion of our produce, and who requires to be very strictly chained up indeed. The paternal theory, whatever charms it may have in the Fatherland, has few charms for English people, in spite of our intermittent relapses into belief in the efficacy of governmental management of individual concerns.

The attempt, however, of the young Emperor to initiate a formal discussion of the labour question by European rulers and statesmen is gallant enough. He may not succeed in effecting any material good by it—it would be passing wonderful if he did—but the natural ambition of a young ruler has at least been gratified. He has propitiated King Mob by an old expedient, with which King Mob has for a time almost invariably rested content. "We must inquire, we must inquire," is, after all, a specious enough cry for most ears; and the Emperor William, disturbed as he has been by the strikes in Westphalia, has become alive to the fact that, with the example of English and American workmen before them, German workmen will not be patient under the military discipline and wretched wages to which they have been accustomed, and therefore his sudden interest in the working class has a feasible enough explanation. It may be that he has been really affected by the position of German labour, and that he has been engaged in economic researches into the "standard of comfort." It is a not uncommon practice for students of such subjects to rise from a study of the elements of them with a burning zeal to redress the wrongs of the whole world at once. There is a suggestion of some such *naïveté* in the rescript of the Emperor. The neophyte jumps to the conclusion that nothing short of wholesale reorganisation by the single governmental act of superior persons will meet the case of the working class, and he forthwith appeals to the world for those superior persons to come forward and reform it. Meantime his own backyard may be breeding a pestilence. In some such form is the Emperor William, who convenes sovereigns together to discuss the wages question of the civilised world, while he naïvely admits that in his own mines things are not as they should be. Indeed, if Germany has been for a time the headquarters of more than one of the schools of political economy, it has also been for a time the headquarters of that exaggeration of the commercial spirit which refuses to discuss with labour, as if employment were not, as it really is, a contract, a matter of business, and not a matter of sentiment. While it would be preposterous to insinuate that industrially Germany is an Augean stable which needs cleansing by this young Hercules, it is fair enough for us to say in reply to his proposals—leave the German workmen and employers to fight it out together as English workmen and employers have done, or, better still, encourage arbitration by facilitating the establishment of, or by establishing, boards of arbitration. But in any case do not begin by demoralising the people you want to serve. If it is the duty of the State "to regulate economic wants"—(surely he means the supply of them and not the wants themselves)—if it is the duty of the State "to regulate health and morals," what is the duty of the individual man? Mazzini's famous essay on "Rights and Duties" should be read, as the antidote of a stout old Republican to such Imperial nonsense as this.

There is a certain importance in the emergence of this question at such times as these, for opinion is indeed seething with new social and industrial ideals, and, though the economic forces are stronger than Emperors, and even than Iron Chancellors behind them, the very expression of such opinions, inept as it is in many ways, is an evidence of the force which such ideas are possessing. Following upon our leader of last week, and our previous consistent declarations on the subject, we may repeat that we view with a kind of disinterested curiosity such efforts as those of the German Emperor, realising, as we must, that after all the State must do but little, because, in the nature of things, it is powerless when the forces are against it. To distrust the action

Digitized by Google

of Governments, to avoid bureaucracy, to shun industrial legislation, and to welcome spontaneous association or individual action for the public good—this, in effect, must be the policy of a new movement separate from all the tweedledum and tweedledee of party politics. If, as is not unlikely, the Convention on Labour which the German Emperor, if he receives sufficient encouragement, must now summon, results merely in admitting the ineptitude of the State to deal, either in wholesale or in retail, with effective amelioration, much good will have been done. A change in the attitude of the public mind towards the powers and sphere of the State may even be effected. The importance of such a Convention would lie, however, not so much in any immediate practical results that might arise from it, as in the mere fact of industrial problems having thrust themselves into the place previously occupied by dynastic and territorial questions. The reception of this proposal by different Governments of Europe, and the alacrity, or want of it, which some of them may exhibit in responding to the invitation, will be very eagerly discussed. More than this, such are the effects of international rivalry, that it would be entirely what might be expected if France, stung by the ursurpation by her rival of a *rôle* to which she herself has some historic claims, embarked on a labour propaganda more drastic even than that proposed by the Germans, and thus disputed with them their position as the friend of the proletariat. History has repeated itself strangely, for there have been times when King and people have combined against the nobles; and now we find the same with a difference—the King attempting to effect an alliance with the people against the middle class. The conflict of modern ideas with ancient forms like semi-despotic monarchy produces strange results indeed.

It may be questioned whether the proposal is at all likely to be accepted gratefully by the extreme party in Germany. They, almost to a man, would regard a Republican form of Government as being a necessary part of such social reconstruction as the Emperor William indicates in his rescript. For the labour question to be settled by a semi-absolute Monarch would not be at all welcome to those who regard political freedom as the only security for industrial freedom.

THE PROGRESS OF FORCED DRAUGHT.

There are few subjects connected with steam engineering about which we have less definite information than what is usually called "forced draught," although the name is not by any means definite. All draught, in a sense, is forced draught, for we have either to pull it along by means of a chimney or blow it along by means of fans or a current of steam. The ordinary chimney has, however, come to be looked upon as the natural method, while the artificial methods in use are: (1) The steam blast, such as we find in locomotives, by which the products of combustion are ejected from the chimney by means of the exhaust steam; (2) an air-blast delivered under the fires with a closed ash-pit, such as has been designed by Mr. Howden; (3) the closed stokehold system, in which the boiler room is made air tight, and air is forced into it by a fan until the pressure is above that of the atmosphere, the only vent being through the furnaces to the funnel. In making comparisons of results, the object in view in applying the forced draught must be clearly kept in mind. If the boiler be simply looked upon as an apparatus for burning coal economically, the closed ashpit system has hitherto been regarded with the greatest amount of favour. But if the boiler be looked upon as an apparatus for generating the greatest amount of steam in a given time, as is required in ships of the navy, it is maintained by those who have had experience of the system that the closed stokehold gives by far the best results that have yet been obtained. Whether the improvements which are being made in this system have been sufficient to combine in it both advantages is a point regarding which, as yet, we have no definite information, and the experience gained by the Inman liners, "City of New York" and "City of Paris," both of which are fitted with closed stokeholds, would be a valuable addition to our knowledge of the subject, and we hope that in due time it will be forthcoming. Mr. Howden's system has been applied to the White Star liners "Teutonic" and "Majestic," and by-and-by their performances will afford a direct measure of the comparative results of the two methods.

Of course Mr. Howden thinks his own system the best, and states that, notwithstanding the improvements which have been made on the stokehold system, he considers it radically defective, and he predicts that two years from this it will be found that it has not been successful. We infer that he means by that time it will have rendered the boilers useless, and, therefore, that the apparent economy has not been real. It is never safe to prophesy, or to rely on a prophecy, and in the absence of definite information we will not venture to express an opinion on the subject. Mr. Howden has, however, published some results of his own system, which will be of interest to marine engineers and shipowners, and of which we will give an abstract.

For what is usually called natural draught in an ocean steamer, the i.h.p. obtained per square foot of fire-grate is from 9 to 12. For an "Atlantic racer" with triple expansion engines, worked up to their utmost possible power, the i.h.p. per square foot with natural draught may be assumed as 12. The "City of Paris," with its closed stokehold, gave 15 i.h.p. per square foot of grate, or an increase of power of 25 per cent. Mr. Howden states that fully eighteen months ago he undertook to refit one of the "Clan" line of steamers with triple expansion engines and one single-ended boiler of 3 furnaces, having 50 square feet of fire-grate, and a total heating surface of 2,338 square feet. From this boiler he undertook to give an average of 1,000 i.h.p. in ordinary working at sea, or 20 i.h.p. per square foot of fire-grate. It was found on trial that the engines gave an i.h.p. of 1,300, or 26 i.h.p. per square foot of grate. The results otherwise were also so satisfactory that the company resolved to have six of their steamers refitted with exactly the same engines and a single main boiler, and the results have been most satisfactory, and they have been taken from actual performances at sea, and not from ordinary trial trips. They show on an average a consumption of coal of 1·25lb. per i.h.p., and 23·66 i.h.p. from each square foot of fire-grate; and if the style of firing which obtains in Atlantic racing steamers were adopted, this could easily be increased to 25 i.h.p. per square foot of fire-grate. Comparing this with the highest natural draught power of 12 i.h.p. per square foot, and 15 i.h.p. per square foot of the "City of Paris" with closed stokehold, it shows an increase of 108 and 66·6 per cent. respectively. The coal consumption in the "City of Paris" has not been published, but 1·25lb. per i.h.p. per hour, the quantity used in the "Clan" liner, is the least known of any sea-going steamer.

Mr. Howden will shortly have completed nine sets of engines and boilers on his system for Messrs. George Smith & Son's Calcutta steamers, so it is quite evident that it is being appreciated by shipowners, not only for its great economy in coal consumption, but also in wear and tear, as compared with boilers with ordinary draught, and he has published evidence on this point, which, however, we need not reproduce. Until we have more definite information with regard to the economical performances of steamers with closed stokeholds, we will not pronounce a definite opinion on the relative merits of the two systems, and we trust that this information will be forthcoming. In the meantime, however, Mr. Howden remarks, that why it is that the use of the closed stokehold system is continued by the Admiralty, and is fitted in Atlantic steamers, when it is shown beyond cavil that a system greatly superior in every respect exists, is a question somewhat difficult to answer. Possibly some of our readers may have some remarks to make on the other side of the question.

COMMERCIAL MORALITY.

"Palm oil" is a colloquial but expressive term to indicate bribes given as so-called commissions to influence orders or to pass work not properly carried out. Most commercial men have noticed the recent case tried before the Central Criminal Court, in which Bell's Asbestos Company figured as prosecutors. As shown by this case authenticated bribing cases are necessarily hard to find, as the parties concerned, for their own purposes, keep the matter to themselves. Bribing is as invisible as a current of electricity, but its presence and influence are just as much felt. The existence of "commissions" is so well known that it is needless to give instances. It is to the advantage of both giver and accepter to keep the matter in the dark. Where, however, certain parties disagree, light is sometimes thrown upon the transaction. The Salford Corporation and the Metropolitan Board of Works cases are possibly within the recollection of most readers. Few persons, however, are aware of the extent to which the practice goes. We have the greatest sympathy with firms who will not tolerate it, for we know instances where the system has been the cause of mischievous results. The coal merchant finds that a complaint is lodged against the coal which he has delivered to a gas company, and he may recollect that he originally obtained the order against adverse influences which he could not fully understand; and this complaint comes forward when the coal contracts are to be renewed. An investigation may show that the gas has not been properly purified, or something has been omitted; but, whatever it is, he loses the contract. The oil manufacturer may find that his lubricant is complained of - the quality is not good, and the bearings heat. An inquiry may possibly show that foreign substances have been introduced into the oil; and that a twist of the spanner has been the cause of the heating. It is hard enough to detect the practice in small concerns, but in large businesses, where the principals do not and cannot look after the details, it is almost impossible. The principal must rely on his assistant to report, and this is necessarily the case with all companies, corporations, and Government departments. We know that the practice has taken a wide root, and that there are good firms who give "commissions." They say in mitigation, but not in defence, that the practice is adopted by competitors, and that, therefore, the "usual commission" must be given. The whole theory of such "commissions" is rotten—the giver is as culpable as the receiver—"It is twice curst." It is a distinct bribe to another person's servant to obtain an order. The price is loaded so as to carry the "commission," which should belong to the purchaser by way of discount, and not to his agent. Payment to one's own agent by way of commission is right enough - lawyers, architects, auctioneers, brokers, and travellers are frequently paid by their own principals in this way. What we do take exception to is the acceptance of commission from anyone but the receiver's own principal. In the report of the case above alluded to, it would seem that the "commissions" paid by the company were entered in their books as "extra wages." If it is an honest practice, why should not they be entered correctly?

So far as we can see, there is nothing to be said in favour of commissions. An employer is entitled to have from his employés and agents unbiassed advice; and he is deprived of the benefit of that advice and judgment if the agent is in the pay of someone else. That particular form of jobbery which is known as "commissions" could be easily put down by a short Act of Parliament making it penal to give them and for an agent to receive them without the consent of his principal. We commend this subject to the notice of any Parliamentary member anxious to improve our commercial morality.

THE RAILWAY AND CANAL TRAFFIC ACT, 1888.

The inquiry before the Board of Trade into the classifications and schedules submitted by the railway companies in compliance with the provisions of the Railway and Canal Traffic Act, 1888, is still proceeding. The case for the companies has been concluded, and that for the traders is now under the consideration of the Court. The prospect of any conclusion of the proceedings within a reasonable time still seems remote, as many witnesses have yet to be called, and sittings will probably have to be held in Wales, Scotland, and Ireland. When the arguments and evidence are concluded the presiding officials will have a mass of matter before them which must involve lengthy consideration. In opening the case for the traders, Mr. Balfour Browne, Q.C., rightly pointed out the extreme importance of the matter to the whole country. If any practical schedule and classification is the outcome of this inquiry the internal trade of Great Britain must be regulated by them for many years to come. A review of railway legislation shows that a long interval has elapsed between the various efforts that have been made by Parliament to regulate railway charges, and it is impossible to conceive, after the enormous expense to which all parties are being put and the very exhaustive inquiry in progress, that railway legislation will be broached again at any rate in the nineteenth century. The traders first complain of the meagre information afforded by the railway companies on the all-important point of the cost of terminals and the general cost of working as compared with actual rates in force, and the maxima for which the companies are now contending. With regard to the vexed question of terminals, the traders admit that some charge should be allowed for loading and unloading, this being already authorised by statute in most instances, but they contend that a maximum charge based on the cost should be fixed by Parliament for every different service performed; that where there exist private sidings or no service is performed a rebate should be allowed; and that as in the case of rates, traders should be entitled to see

Digitized by Google

particulars of every terminal charge made. With regard to the classification, complaint is made that many articles are not specified, and that every article known to commerce must be included. It is also contended that there should be one classification only, instead of a statutory or maximum, and a working or current one, as proposed by the companies. It is a stereotyped assertion that the proposed classification involves rates higher than those now in force, in order to leave a margin for heavier charges in times of good trade, or to meet contingencies, and that there is no immediate intention of bringing them to bear. The traders insist that one working classification with fixed rates is essential.

To put the whole matter briefly, the railway companies are making every effort to not only maintain their existing charging powers, but to increase them, while the traders are engaged in the apparently somewhat forlorn hope of materially reducing them.

COAL, IRON, AND COGNATE INDUSTRIES.

The Board of Trade Returns for the first month of the present year have now been issued, and in relation to the industries under review must be considered of a satisfactory character. The total value of the imports was £38,143,850, being an increase of £85,532 as compared with January, 1889. The total value of the exports was £21,586,752, being an increase of £1,059,715 as compared with January, 1889. The total quantity of iron and steel exported was 302,751 tons, valued at £2,531,563, as compared with 300,324 tons, valued at £2,158,679, in January, 1889. We append our usual tabular statement :—

	Month of January, 1890.		1889.
Pig and puddled	£246,702	...	£153,690
Bar, angle, &c.	137,160	...	135,925
Railroad.....	538,682	...	376,275
Cast and wrought	484,238	...	398,969
Hoops, sheets, &c.....	341,942	...	327,541
Unwrought steel	147,504	...	106,842
Unwrought copper	165,118	...	53,224
Coals	1,356,001	...	1,059,683

Turning to the home markets we find a feeling of uncertainty with regard alike to the course of demand and prices. The speculative "bearing" of the Scotch and North of England markets, which has proved so successful, has disorganised the army of buyers. The feeling of confidence which prevailed at the opening of the new year has given way to one of doubt, and, in the minds of those inclined to pessimism, to one of fear. It is, perhaps, unwise to prophesy, as the course of trade is notably of a vagrant character, but the signs of the commercial times still point to a further measure of improvement. It is quite possible that during the next few weeks the Glasgow "bears" may turn to "bulls," and a sharp rally in prices occur. Legitimate trade is still good, and the order books of manufacturers bear evidence that a large bulk of business is still being transacted.

CLYDE SHIPBUILDING IN JANUARY.

The first month of the new year has given decided indications of a coming lull in the shipbuilding industry. The paucity of orders booked throughout the country is remarkable, and only two vessels of about 1,000 tons were secured by Clyde shipbuilders. The number of inquiries, too, fell considerably below the average for the past five or six months. This may in a measure be attributed to the less profitable rates of freight which now exist.

The total tonnage launched was 19,712 tons, which exceeds the average for the corresponding month during the last ten years by about 6,000 tons. The most noteworthy vessel put into the water was the high speed paddle steamer "Princess Victoria," built by Messrs. William Denny & Brothers, Dumbarton, for the joint committees of the Portpatrick and Wigtownshire Railways for their service between Larne and Stranraer. Her principal dimensions are:—Length between perpendiculars, 280ft. ; breadth, 35·5ft. ; and depth, 14ft. In this vessel a new departure has been made from the ordinary practice in paddle steamers, by placing the first-class accommodation amidships immediately forward of the machinery.

The following are the particulars of the vessels launched during the month :—

Screw Steamers.

By Messrs. Caird & Co., Greenock :—"Wistow Hall," 3,200 tons. Built of steel, and fitted with triple expansion engines of 2,000 i.h.p. by Messrs. Caird & Co., for general cargo trade. Owners, Sun Shipping Company, Liverpool.

By Messrs. R. Duncan & Co., Port Glasgow :—"Ascension," 450 tons. Built of steel, and engined by Messrs. Rankin & Blackmore, Greenock, with triple expansion engines. Owners, Messrs. Morton & Williamson, Glasgow.

By Messrs. D. Dunlop & Co., Port Glasgow :—"Francisco Vidiella," 450 tons. Built of steel, and engined by the builders. Owners, Messrs. Vincente, Martinez, & Co., Monte Video.

By Messrs. Fullerton & Co., Paisley :—"Rostrevor," 200 tons. Built of iron, and fitted with compound engines by Mr. Wm. Kemp, Govan. Owners, the Newry and Kilkeel Steamship Company.

By Messrs. Murdoch & Murray, Port Glasgow :—"Roseneath," 2,650 tons. Built of steel, and supplied with triple expansion engines by Mr. Wm. Kemp, Govan. Owners, Messrs. P. H. Dixon & Harrison, Glasgow.

By Messrs. Mackie & Thomson, Govan : —"Persis," 1,900 tons. Built of steel, and fitted with triple expansion engines of 900 i.h.p. by Messrs. Muir & Houston, Glasgow. Owners, Messrs. Aitken & Walker, Glasgow.

By Messrs. Murray Bros., Dumbarton : —A screw steamer, 450 tons. Built of steel, and engined by Messrs. Matthew Paul & Co., Dumbarton, for Clyde owners.

By Messrs. McArthur & Co., Paisley :—"Nautilus," 360 tons. Built of steel, and fitted with engines of 350 i.h.p., for coasting traffic. Owners, Messrs. Webster & Co., Cape Town.

By Messrs. Russell & Co., Port Glasgow :—"Bremerhaven," 3,330 tons. Built of steel, and fitted with triple expansion engines by Messrs. Duncan Stewart & Co., Glasgow, for the oil trade between New York and the Continent. Owners, Messrs. Herman Stursberg & Co., New York.

Paddle Steamers.

By Messrs. Wm. Denny & Bros., Dumbarton :—"Princess Victoria," 1,000 tons. Built of steel, and engined with compound engines by Messrs. Denny & Co., Dumbarton, for passenger and cargo traffic. Owners, Portpatrick and Wigtownshire Railways Joint Committee.

By Messrs. A. & J. Inglis, Glasgow : —"Rasmara," 900 tons. Built of steel, and supplied with engines of 2,000 i.h.p. by the builders, for service between Rangoon and Moulmein. Owners, British India Steam Navigation Company.

Sailing Vessels.

By Messrs. D. & W. Henderson, Partick : —Six lighters, 222 tons each. Built for the Colonial Sugar Refining Company, for trade in the Australian rivers.

By Messrs. Russell & Co., Port Glasgow :—"Glen Cona," 2,500 tons. Built of steel. Owners, Messrs. W. O. Taylor & Co., Dundee.

By Messrs. A. Stephen & Sons, Govan : —"Fascadale," 2,100 tons. Built of steel. Owners, Messrs. J. & A. Roxburgh, Glasgow.

Letters to the Editor.

CONTINUOUS BRAKES FOR GOODS TRAINS.

To the Editor of "Industries."

Sir,—I was pleased to see your article on "Large Railway Trucks for Mineral Traffic," published in your issue of the 24th ult., and also the letter of Mr. R. Jefferds, in your issue of last week, drawing attention to the importance of light weight, high capacity, bogie truck freight cars in the economy of railway working. Equally important in my opinion is the equipment of goods trains with quick-acting continuous brakes. This is another instance in which American practice is in advance of English practice. The introduction of large railway trucks will facilitate the introduction of continuous brakes, as the cost of equipment with a powerful brake is practically the same whether the truck is large or small. Many of the freight trains in the States are now fitted with these quick-acting brakes. In some trials made by the Westinghouse Brake Company in the United States with 50 freight cars it was found that the farthest brake from the engine was applied in two seconds, thus making the application of the brakes on each car practically instantaneous.

As the velocity of compressed air at 60lb. above the atmosphere is about 1,800ft. per second, and as the brake is applied 1,900ft. from the engine in two seconds, the air passes through the train at nearly its maximum speed. A whole train of fifty cars at forty miles an hour was brought to a stand in 580ft. on the level. In one instance, the train running at nineteen miles an hour was stopped in 78ft., two car lengths.

The introduction of continuous brakes on goods trains would enable the speed of the service to be increased, besides avoiding the frequent accidents which we hear of happening to goods trains, but which, as they only destroy rolling stock and plant, are not dwelt upon so largely as if life and limb were at stake. The placing of a good, reliable, rapid continuous brake in the hands of the engine driver would be like placing a good helm to a ship in the hands of the steersman. The engine driver would run his train quickly on its journey, steering his way at any speed he desires, through the network of signals on his route. The train, regulated by the driver's valve, answers to the slightest touch of the driver from stop up to full speed ; and thus, paradoxical as it may appear, a good, reliable, rapid brake for stopping the train would actually increase its speed, and enable the journey to be more quickly performed, thereby saving the time of drivers and guards and the expenditure of fuel burnt on the journey.

Those of your readers who travel on the Brighton line will have noticed the speed with which the passenger trains come running into the stations, and how quickly they are brought to rest, the driver having in his hands a reliable and powerful brake in which he can put confidence and which he uses at the right moment.

The cost of equipping goods trains with continuous brakes would be saved if only one accident was prevented. Our English companies are rather slow to act in introducing new features into their working, but one would have thought that the experience of numerous accidents would have led them ere this to the use of continuous brakes for all trains, without waiting for the States to lead the way. Even now, although continuous brakes have been in use for many years on most passenger trains, yet it has been found necessary at last for the Board of Trade to compel the adoption of automatic continuous brakes to *all* passenger trains. Let us hope that so many years will not elapse before the same rule is applied to goods trains, and that shortly we shall find the same brake power in use for goods traffic as for passenger traffic. My impression is that, as the greatest economy is found with large trucks for mineral and other heavy traffic, so will that economy be increased by using the quickest, lightest, and most reliable continuous brake.

Yours, &c.,

J. E.

London, February 11th, 1890.

STEAM BOILER LEGISLATION.

To the Editor of "Industries."

Sir,—Those of your readers who have taken sufficient interest to read my letter of the 24th ult. under this heading will agree that Mr. Young's attempt to dismiss it in his letter in your last week's issue as a mere attack upon his "district inspector" is a very small device. No such thing was intended, and it will not bear any such construction. It is and was intended as an attack upon the stand taken by the Scottish Boiler Insurance Company in declaring "they held no duty to the insured," and particularly with regard to their carrying their views into practice, by not even sending an inspector of any kind to see the boiler of the s.s. "Perseverance" before insuring it, it being my opinion, and probably that of all competent boiler inspectors, that reliable inspection is the only reason for the existence of boiler insurance companies. I think Mr. Young has unnecessarily brought the name of his district inspector into the matter. The real question at issue does not refer to an individual only, but to the class and requirements of inspectors employed by boiler insurance companies.

I enclose for your perusal transcript of the evidence taken by the shorthand clerk to the Commissioners of the Board of Trade at the formal investigation upon the cause of the explosion of the boiler of the s.s. "Perseverance," from which you will see that the expressions I have quoted in my letter of the 24th ult., relating to the manner in which the Scottish Boiler Insurance Company performs its duties and carries on its business, were made by Mr. J. D. Young, managing director, and by Mr. Henderson, the counsel appearing for this company, and in the exact words I used.

It is difficult to see, therefore, where the "obvious inaccuracies," Mr. Young refers to in my letter, exist.

Yours, &c.,

Boiler Inspector.

Manchester, February 11th, 1890.

ADJUSTMENT OF LABOUR DISPUTES.

To the Editor of "Industries."

Sir,—We have the honour to enclose you a copy of the final report of the Conciliation Committee of this Chamber, as adopted at the Special Council meeting, held on the 6th inst.—We are, Sir, yours faithfully,

John Lubbock (President).
Kenric B. Murray (Secretary).

Further Report of the Labour Conciliation Committee to the Council of the London Chamber of Commerce.

Your Committee has endeavoured to devise some practical methods for carrying out the scheme contained in the interim report provisionally adopted by the Council on the 12th December.

The Committee offers the following suggestions :—

I. That a permanent body be constituted, to be called "The London Conciliation Board," which shall be affiliated to the London Chamber of Commerce, and that its composition shall be as follows, viz. :—

(*a*) Twelve members representing Capital or Employers, to be elected by the Council of the Chamber.

(*b*) Twelve members representing Labour, to be elected by the employed.

(*c*) To these shall be added representatives from the separate Trade Conciliation Committees as hereinafter referred to.

(*d*) The body thus constituted shall add to their number six other members, who from their position, authority, or experience, may be useful in promoting the objects of the London Conciliation Board, three to be appointed by the Labour representatives on the Board, and three by the representatives of Capital.

(*e*) Four members—viz., the Lord Mayor of London, or some member of the Corporation to be nominated by him, the Chairman of the London County Council, or some member of the Council to be nominated by him, a representative of the London Trades Council, and a representative of a London Labour Organisation to be selected by the Labour Representatives on the Board.

The elections shall take place every three years, and the first election shall take place on the

II. The duties of the London Conciliation Board shall be as follows :—

(*a*) To promote amicable methods of settling Labour disputes and the prevention of strikes and lock-outs generally, and also especially in the following methods :—

1. They shall, in the first instance, invite both parties to the dispute to a friendly conference with each other ; offering

Digitized by Google

the rooms of the Chamber of Commerce as a convenient place of meeting. Members of the Committee can be present at this conference, or otherwise, at the pleasure of the disputants.

2. In the event of the disputants not being able to arrive at a settlement between themselves, they shall be invited to lay their respective cases before the Committee, with a view to receiving their advice, mediation, or assistance. Or, should the disputants prefer it, the Committee would assist them in selecting arbitrators, to whom the questions at issue might be submitted for decision.
3. The utmost efforts of the Committee shall in the meantime, and in all cases, be exerted to prevent, if possible, the occurrence or continuance of a strike or lock-out until after all attempts at conciliation shall have been exhausted.

The London Conciliation Board shall not constitute itself a body of arbitrators except at the express desire of both parties to a dispute, to be signified in writing, but shall in preference, should other methods of conciliation fail, offer to assist the disputants in the selection of arbitrators chosen either from its own body or otherwise. Any dispute coming before the Board shall, in the first instance, be referred to a Conciliation Committee of the particular trade to which the disputants belong, should such a Committee have been formed and affiliated to the Chamber.

(*b*) To collect information as to the wages paid and other conditions of labour prevailing in other places where trades or industries similar to those of London are carried on, and especially as regards localities either in the United Kingdom or abroad where there is competition with the trade of London. Such information shall be especially placed at the disposal of any disputants who may seek the assistance of the London Conciliation Board.

III.—The separate Trade Conciliation Committees shall be composed of equal numbers of employers and of employed.

Each trade shall elect its own representatives, employers and employed voting separately for the election of their respective representatives. The number of members and the general rules of procedure shall be determined by each particular trade, subject to the approval of the London Conciliation Board.

The Trade Conciliation Committees shall be affiliated to the London Chamber of Commerce, and shall be represented upon the London Conciliation Board. Any Trade Conciliation Committee constituted as above, representing a body or trade in the Metropolitan districts of more than 1,000 individuals, shall send two representatives to sit on the London Conciliation Board, one being an employer and the other an operative workman, each to be separately elected by employers and employed respectively. In the case of Trade Conciliation Committees representing bodies or trades in the Metropolitan districts smaller in number than 1,000 individuals, two or more such committees may unite together to elect joint representatives to the London Conciliation Board.

It shall be the duty of the Trade Conciliation Committees to discuss matters of contention in their respective trades; to endeavour amicably to arrange the same, and in general to promote the interests of their trade by discussion and mutual agreement. In the event of their not being able to arrange any particular dispute, they will refer the same to the London Conciliation Board, and in the meantime use their most strenuous endeavours to prevent any strike or lock-out until after the London Conciliation Board shall have exhausted all reasonable means of settlement.

They may from time to time consider and report to the London Conciliation Board upon any matter affecting the interests of their particular trade upon which it may be thought desirable to employ the action or influence of the London Chamber of Commerce as a body.

IV.—The London Chamber of Commerce places its rooms at the disposition of the London Conciliation Board and of the Trade Conciliation Committees for holding their meetings. Any alterations in the rules and regulations of these bodies which may be from time to time proposed shall be submitted for approval to the Council of the Chamber.

V.—The above regulations shall be subject to bye-laws, to be specially framed for the purpose, and which shall be open to amendment as required from time to time, on agreement between the Council of the Chamber of Commerce and the London Conciliation Board.

Signed { His Eminence Cardinal Manning. / The Right Honourable Sir Henry Isaacs (Lord Mayor of London). / Sir John Lubbock, Bart., M.P. / Sir Albert Rollit, M.P. / Sir James Whitehead, Bart. / Sir Vincent Kennett-Barrington. / R. K. Causton, Esq., M.P. / Samuel Montagu, Esq., M.P. / S. B. Boulton, Esq. (Chairman). / H. O. Arnold-Forster, Esq. / E. H. Carbutt, Esq.; and / Kenric B. Murray (Secretary). } Members of the Committee.

Reviews.

"The Electrician" Electrical Trades Directory and Handbook for 1890. "The Electrician" Printing and Publishing Company, Limited.

There is nothing very new to be said about the latest issue of the "Electrical Trades Directory." Information on current topics is up to date, and the general tables and data are gradually being perfected. Mr. Curtis Hayward has specially written a "Digest of the Law of Electric Lighting" for this issue of the Directory, and the book also includes a series of useful notes on "Patents, Designs, and Trade Marks," by Mr. J. C. Chapman. In looking through the Biographical Notices we are struck with the absence of some well-known names. We would suggest also that the names should be in strict alphabetical order. The portraits are still of a very low order; indeed, it is a question whether the subjects of them consider themselves flattered or otherwise by the inclusion of their portraits in the series.

We must give the compilers of the Directory great credit for their work, for a vast amount of research and accurate method is required in bringing a publication of this sort to such perfection.

Modern Workshop Practice, as applied to Marine, Land, and Locomotive Engines, Floating Docks, Dredging Machines, Bridges, Shipbuilding, Cranes, &c. By John G. Winton, Author of "Modern Steam Practice," &c. London: Crosby Lockwood & Son. 1889.

This book is one of Weale's Rudimentary Series, and in the sample before us has attained to the honour of a fourth edition, which is stated to have been "much enlarged and carefully revised." The new matter, which occupies somewhat over forty pages, relates chiefly to locomotives, gas and its manufacture, and steam fire engines. As the book is of small size, and the total number of pages is only 342, with moderately large type, it will be evident, from the imposing list of subjects with which the work is supposed to deal, set forth in the title, that the majority of these must necessarily be very briefly handled. The bulk of the space has been devoted to marine, locomotive, and land engines, and shipbuilding; on some of the other subjects so little is written that it is difficult to understand why they were not omitted altogether. A very large proportion of the information on marine engines and shipbuilding is obsolete; with the exception of a few pages of generalities on high-speed engines, and about three-quarters of a page on steel ships, this part of the work seems to have been simply transferred wholesale from one edition to another. As the particulars given are mainly of a class which if not up to date are almost worse than useless, the defect is especially unfortunate. The matter relating to locomotive engines is somewhat better, because, in the first place, it comprises much of the additions to the present edition, and, in the second place, the alterations effected in locomotive practice have not been during the last twenty years of such a sweeping character as those introduced in marine engineering. Even in this department, however, the detail drawings shown appear to be of rather ancient date. Considering the general character of the work we are agreeably surprised to find compound locomotives, including those made by Mr. Webb, mentioned at all, although the statements regarding them cannot be credited with any specific value. To land engines a few pages are devoted, for the greater part to single-acting pumping and beam engines of a type rendered venerable by age. Bridges are disposed of in nine and a half pages, while on "Air Furnaces in General Use" we are treated to five pages, and, to conclude the volume, half a page on "Tools" is thrown in.

In its present state we cannot conscientiously recommend this book. It is hard to say, after perusing it, which feeling predominates in our mind, wonder as to why it should have been published, or surprise that, being published, it should have attained a fourth edition. To be of any real use, "Modern Workshop Practice" must be entirely re-written, and embrace not more than two subjects instead of half a dozen.

THE PHYSICAL SOCIETY.

The annual general meeting of the Physical Society was held on the 7th inst., Professor Reinold, F.R.S. (President), in the chair. The reports of the Council and of the treasurer were read and adopted. The former stated that there had been a very satisfactory increase in the number of members during the year. The number now exceeded 360, of whom 80 were Fellows of the Royal Society. During the year the Council had proposed to change the time of meeting of the Society from Saturday afternoon to Friday evening. The change was adopted by the members by a vote of 129 to 30, and had resulted in a larger attendance at the meetings. During the year the second volume of the translations of important foreign memoirs had been issued to the members, and it was hoped that a third volume would be published early in the present session. The Council had to regret the loss by death of three well-known members—James P. Joule, Warren de la Rue, and Father Perry. A valuable collection of books had been given to the Society by the Royal Astronomical Society. From the treasurer's report it appeared that the balance of the Society had been increased by £120 during the year. The result of the new election of officers was declared as follows:—President, Professor W. E. Ayrton, F.R.S.; vice-presidents, Dr. E. Atkinson, Walter Baily, M.A., Shelford Bidwell, F.R.S., and Professor S. P. Thompson, D.Sc.; secretaries, Professor J. Perry and T. H. Blakesley, M.A., M.I.C.E.; treasurer, Professor A. W. Rücker, F.R.S.; demonstrator, C. V. Boys, F.R.S.

The paper on "Galvanometers," by Professor W. E. Ayrton, F.R.S., Mr. T. Mather, and Dr. W. E. Sumpner, was then resumed by Professor Ayrton. A long table of numbers accompanying the paper, and representing the results of experiments on many galvanometers, was explained. From this it appeared that galvanometers of the D'Arsonval type were exceedingly efficient in proportion to the amount of wire used in the coils. It was for this reason that voltmeters with strong permanent magnets could be made sensitive even with an exceedingly large external resistance in series, so as to diminish the power absorbed by the instrument. The space occupied by the wire was so exceedingly valuable that the extra resistance did not too much diminish the sensibility. The most sensitive galvanometers should, therefore, be made of the permanent magnet type. If, however, the magnets were to form part of the moving system, as in most galvanometers, the experiments showed that instruments of the Rayleigh, Gray, or Rosenthal type were the best. The coils should be numerous and small as Mr. Boys had previously shown. As an astatic system of needles sets itself perpendicular to the earth field, it was recommended that astatic galvanometers should be placed so that the needles pointed east and west. The controlling magnet would then not need to be turned round as it was raised or lowered. It was recommended to calibrate low resistance ballistic galvanometers for quantity by measuring the deflection for a known current. This obviates the necessity for large condensers or high potentials. The method, although not new, is not described in text-books. In conclusion, Professor Ayrton asked for information with regard to microscope galvanometers.

Mr. C. V. Boys thought that the factor of merit of galvanometers should not be given in scale divisions per micro-ampere under the condition of constant controlling moment. This gave too great an advantage to instruments of the Gray or Rosenthal type. Great sensibility could be obtained by diminishing the moment of inertia of the suspended parts, the practical limit being determined by the trouble due to the silk fibre. Spider lines, when used in place of silk fibres, gave better results. It was possible, by using a good suspending arrangement, to use needles $\frac{1}{8}$in. long and a period of 20 seconds, and to gain a sensibility far greater than those indicated in the paper. Ballistic galvanometers should be made with needles as light as possible. The method proposed of winding the central part of the coil in the opposite sense to the rest would probably not be good, owing to the unevenness of the field produced. The conclusion come to by the authors, that D'Arsonval galvanometers of great sensibility should be made with small coils placed in a very strong field, was one he had himself come to, but had finally abandoned, owing to difficulties caused by diamagnetism in the copper, and to excessive damping due to Foucault currents.

Mr. J. Swinburne thought that the factor of merit of a galvanometer should be determined differently according as it was to be used for the measurement of current or quantity, or for null methods merely. He saw no great advantage in making practical instruments proportional. The name D'Arsonval should be dropped, as the instrument denoted by it was invented by Varley years ago. He would like to know the relative sensibility of the telephone and the Lippman galvanometer.

Professor Fitzgerald stated that Lord Rayleigh had shown that the microscope method of observing angular deflections was as sensitive as the ordinary method of mirror and scale, even when only the mirror was used as a pointer, so that if a pointer were attached it would be far more sensitive. The drawback, however, was that it was impossible to distinguish with the microscope between lateral displacements of the needle and the angular motion whose measurement was required. To get over this error it was necessary to read both ends of the pointer, but this was hard to do.

Professor Ayrton replied to the different points raised in the discussion.

THE POLLOK GOLD EXTRACTING PROCESS.

Some months ago we referred to this interesting process for the extraction of gold from its ores. Since then, however, much progress has been made towards carrying out the process on more of a commercial scale than had at that time been attempted, and although the present works of the company, situated in Old Keppochhill Road, Glasgow, which we had an opportunity of visiting on the 29th ult., are still little more than what might be called experimental works, they are sufficient to test the value of the process as a commercial success.

The Pollok process is, like the great majority of gold extracting processes which have been hitherto patented, a *chlorination* one—*i.e.*, the reagent used for the purpose of dissolving out the gold from its ores is chlorine. The special feature of the Pollok process is the method in which the chlorine is applied—a so-called *hydraulic* chlorination method—*i.e.*, the chlorine after being liberated is liquefied by hydraulic pressure. This process, it is claimed by the patentees, is applicable to all ores or tailings containing gold, and especially to refractory and float gold ores. Being an eminently cheap process, the estimated cost of treating a ton of ore under present circumstances being not more than eight or nine shillings, it will be seen to be peculiarly suited for dealing with that large class of refractory ores which are unable to be treated by the older and more expensive amalgamation processes, which consequently have hitherto been allowed to accumulate in such large quantities in different parts of the world. As the process thus promises to be of great commercial importance, a more detailed account of its methods may not be without interest to our readers.

The works at Keppochhill Road have been in operation for the last two months. The gold ore at present under treatment is from Chili. It contains, according to assay, 3 oz. 6 dwt. per ton. Out of this quantity of gold 3 oz. 1 dwt. is extracted by means of the Pollok process. The following are the different operations which the ore is submitted to in this extraction process. The ore is first crushed by an ordinary crusher, and is rendered sufficiently fine to pass through a sieve containing 30 meshes to the linear inch. Too great fineness, it may be remarked in passing, is not desired in this process, as it is found to impede subsequent operations. In the case of very refractory ores a greater degree of fineness is desirable than in ordinary ores. In the case of what are known as float gold ores, the ore is brought, immediately after being ground, to the chlorinating cylinder. In the case, however, of refractory ores containing sulphur, iron pyrites, copper, lead, &c., the ore must be previously roasted. The object of roasting the ore, in such a case, is to remove the sulphur, oxidise the iron, &c., and thus to render the ore of a porous nature. The result of such previous roasting is to save the chemical reagents afterwards used, and to permit of the gold contained in the ore being more easily dissolved by the chlorine. In the case, however, of very poor refractory ores, the ore before being taken to the furnace is treated in a stamp battery and concentrated by vanners. In this way a very poor ore, which it would be impossible to treat profitably otherwise, is concentrated some ten times. Thus, an ore containing no more than 5 dwt. of gold per ton can, under favourable circumstances, be worked with profit.

The furnace at present used by the Pollok Company for roasting their ores is the common hearth furnace, and holds some 2½ to 3 tons at a time. It is capable of roasting about 12 tons of ordinary ore in a day, and burns in the operation about 1½ tons of coal. In working abroad, however, the company purpose using a revolving furnace holding 8 tons at a charge. This furnace, it is calculated, would be capable of roasting 30 tons of ore in a day, and would burn from 2 to 3 tons of coal. The chief benefit of a revolving furnace, it may be here pointed out, is that it feeds, stirs, and discharges automatically, thus saving labour—a most important consideration abroad. The time required for roasting the ores varies with the nature of the ore, some requiring a very much longer period than others. The average time is from four to six hours. Ores which have been previously concentrated in the manner above described require a considerably longer time. After being roasted the ore is raked out on to a cooling floor. It is next conveyed to the chlorinating cylinders (Figs. 1 and 2), of which there are two at present in work. One of these (Fig. 1), designed by Mr. Stephen Alley, is made of light steel—it only weighs 25 cwt.—and is lined with a thin coating of india-rubber, which protects the steel from the action of the chlorine. It has an automatic valve for charging and discharging, and a delivery pipe. There is also an escape valve on the top of the cylinder. The other cylinder, we may mention, is lined with wood. The rubber used for the purpose of lining the cylinder is about an eighth of an inch in thickness, and is made of pure rubber and not

* Three-fourths of this gold can be obtained by a second chlorination.

vulcanised. It is found that the chlorine has no action on the rubber, and that the wear and tear from friction practically amounts to nothing. It will be seen that the value of the india-rubber lining is thus very great. The chlorinating cylinders are charged as follows:—First, 80lb. of nitre cake—forming about 2 per cent. of the whole charge—is dropped into the cylinder; then two tons of the ore; and lastly, 60lb. of bleaching powder—or about 1½ per cent. of the whole charge. The charging aperture is then closed, and a steam injector is turned on, forcing in water till the pressure rises from 70lb. to 100lb. It is important that all the air in the cylinder should be allowed to escape, as the presence of air is most detrimental to the action of the chlorine, as it mixes with the gas and prevents it liquefying. The cylinder is then revolved, thus mixing up the ore with the bleaching powder and the nitre cake. The chlorine which is thus liberated goes into solution, and the pressure forces the strong chlorine liquor into the pores of the ore, previously rendered porous by roasting. The period during which the cylinder is revolved varies from one hour to an hour and a half. At the end of this time the contents of the cylinder are discharged on to a filter bed placed below. The waste chlorine is blown off, and largely recovered by being passed through slaked lime and thus absorbed. The filter is made of steel wire lined with india-rubber. The charge after being decanted on to the filter bed is filtered, the chlorine liquor, containing the gold, is drawn off by a specially designed vacuum pump, by which it is pumped into the precipitating tank (Fig. 2), where the gold is precipitated by adding ferrous sulphate. The quantity of this reagent used is about 30lb. to the ton, or 1½ per cent. The precipitating tank is fitted with a conical-shaped bottom, on which the gold precipitate settles. As soon as the liquor has become clear it is run off, and the gold paste is removed and fused, in Hessian crucibles, with borax into gold bars.

The chief advantages of this process, as claimed by the patentees, are:—(1) The rapid and complete extraction of the gold by the use and application of hydraulic pressure, a machine weighing 25 cwt. being able to put through 24 tons in twelve charges in twenty-fours; (2) the use of dry chemicals, which can all be safely and cheaply packed, shipped, and carried.

The table embodies some of the results obtained by the treatment of ores by the Pollok process.

THE INSTITUTION OF ELECTRICAL ENGINEERS.

At the meeting of this Institution, on the 13th inst., Mr. James Swinburne read a paper on "The Theory of Armature Reactions in Dynamos and Motors," of which we give an abstract as follows:—

It seems to be generally supposed that electrical engineers are in full possession of means for designing a dynamo or motor. This is no doubt the case as regards very small machines, and when considered with reference to no load. As not only the excitation necessary at full load, but also the best dimensions of the magnets and the proper shape of the pole-pieces, depend on the armature reactions, and as the armature reactions are of immense importance in large machines, such machines cannot be designed with accuracy unless the armature reactions and position of the brushes at full load can be foretold. The magnetic potential will be denoted by the symbol Ω; and for want of a unit of its own, it may be measured in ergs. An ampere-turn thus gives a magnetic potential of $4\pi/10$ ergs, or 1·26 ergs.

As single-magnet machines are very largely used now, and a type can be taken which is approximately that used by most of the large representative makers, such a machine may be taken as an example. A formula which gives the size of iron, and the excitation needed, will then be worked out.

The vertical line through the centre is taken as at zero magnetic potential at no load. Assuming the length of the core to be the same as that of the pole-pieces, and calling the external radius of the core r, and the radial depth of the discs b, and the length of core a, and the armature induction B_a, the surface integral of the induction, or what may be for shortness called the total armature induction, is $2\,a\,b\,B_a$. The desired armature induction is here assumed. The distance, l_a, which represents the length of iron that has to be magnetised to the induction B_a, depends on the arc of embrace of the pole-pieces; but a large error in the estimate of this length causes a very small error in the design of the machine, as very little of the excitation is spent on this part of the magnetic circuit. The fall of magnetic potential over $\frac{1}{2} l_a \frac{1}{2} l_a B_a/\mu$, and may be written $\frac{1}{2}\Omega_a$. The induction in the air gap depends on the armature induction, the radial depth of the discs, and the pole-face angle. It will be written B_g. The line integral of the induction across the gap is $\frac{1}{2} g B_g$, where g is the distance across the gaps. $\frac{1}{2} g B_g$ may be written $\frac{1}{2}\Omega_g$. The fall of potential from the middle of the yoke to the pole-piece depends on the length of the circuit and the induction. It may be written $\frac{1}{2} l_m B_m \mu$, or $\frac{1}{2}\Omega_m$. As the other half of the magnetic circuit is similar at no load, the line integral of the magnetic force needed in the shunt is $\Omega_s = \Omega_m + \Omega_g + \Omega_m$. As to the length of the field magnets, it depends on the total excitation needed.

At full load the armature induction has to be increased to allow for the resistance of the armature and series coils, and sometimes for the leads also. A higher value is therefore taken for B_a, and therefore for Ω_a. The effect of the armature current itself may be divided into two components; and in the case of a drum armature, which may be taken for the sake of simplicity, the electrical effect is the same as if the external conductors were connected across the ends as shown in Fig. 1. There is thus a belt of current-turns opposing the field excitation, and another belt acting at right angles to it. These may be called the back and the cross ampere-turns, and the induction produced by them, the back and the cross induction respectively. The breadth of these belts, or the number of turns in each, depends on the lead of the brushes. For the present the lead of the brushes may be assumed. The extra difference of magnetic potential between the pole-pieces due to the back current-turns is $\pi C n_b/10$, where C is the armature current in amperes, and n_b the number of external armature conductors in the belt of back turns, n_a being the number of external armature conductors. This may be written,

$$\Omega_b = \pi\ C\ n_b/10 \qquad \ldots\ldots(1)$$

The difference of potential of the pole-pieces at full load is this: $\Omega_a + \Omega_b + \Omega_g$; and Ω_a and Ω_g are greater than at no load, because the armature and gap induction are higher. The difference of potential between the pole-pieces may be shortly written, Ω_p. In a given type of dynamo the percentage of waste field varies directly as the difference of potential of the pole-pieces, provided the field magnets are not strongly magnetised, and is independent of the linear dimensions. The actual waste field, however, varies directly as the difference of magnetic potential between the pole-pieces, and directly as the linear dimensions, or as the diameter of the armature. If the armature cross-sectional area is $2\,a\,b$, and the armature induction is B_a, and if the field induction desired is B_m, the cross section of the field magnets must be

$$A_m = 2\,a\,b\,B_a/B_m + r\,\Omega_p/M\,B_m \qquad \ldots\ldots(2)$$

where M is a coefficient depending on the type of the machine. This coefficient can be readily determined from another machine of the same type but of different size, and an error in its estimation makes comparatively little difference in the dynamo.

In ordinary single-magnet machines M is generally above ·08 to ·085; in double-magnet machines it is less. Of course a great deal depends on the mounting of the dynamo. A machine let into a bed-plate, as is often necessary in the case of direct-coupled engines, has more leakage.

An equation for the shunt and series excitation is now to be found. From (1) the field induction is found—

$$B_m = 2ab\ B_a/A_m + r\Omega_p/MA_m \qquad \ldots\ldots(3)$$

Giving the value of B_a and Ω_p at no load, the value of B_m at no load is obtained. The shunt excitation is thus

$$\Omega_s = l_a\ B_a/\mu_a + g\ B_g + l_m\ B_m/\mu_m \qquad \ldots\ldots(4)$$

in ergs, or this number divided by 1·26 in ampere-turns. By giving the full-load values of B_a and Ω_p the total excitation,

$$\Omega_s + {}_m = l_a\ B_a/\mu_a + \pi\ C\ n_b/10 + g\ B_g + l_m\ B_m/\mu \qquad \ldots\ldots(5)$$

is obtained, and, of course, the difference gives the series excitation. Of course the full-load field induction has already been assumed in finding the size of the magnets.

It must not be forgotten that all this time it has been assumed that the load of the brushes, and therefore Ω_b, is known.

Returning to Fig. 1, a closed line, $a\,b\,c$, may be drawn which is interlinked with all the armature conductors under the pole-piece. The magnetic potential round this circuit is

$$\Omega_c = \theta\ n\ C/10 \qquad \ldots\ldots(6)$$

where n is the number of armature conductors, and C is the armature current as before, and θ is the angle of embrace of the pole-piece. As the permeability of the iron, both in the part of the armature and of the pole-piece through which this line passes, is great, the whole difference of potential may be taken as being between the core and pole-piece. The induction under the leading corner, due to cross current-turns only, is then $-n\,C\,\theta/2g \times 10$, and under the trailing corner it is $+n\,C\,\theta/(2g \times 10)$. The field is thus weakened under one corner, and, provided the permeability of the iron is practically infinite, equally strengthened under the other, being at its normal value half-way down. The cross induction has in this case no direct effect in increasing or lessening the e.m.f. of the machine. If a dynamo were enlarged to scale, the field excitation would increase as the linear dimensions, but the armature current-turns, assuming the same current-density, would increase as the square of the linear dimensions. Machines with single magnets, and fairly large outputs for the size of their armatures, become difficult to design when they have armatures above 35 to 40 cm. diameter. If the pole-pieces are made small, so as to carry the induction due to the field coils without saturation, one side will be to some extent saturated

Digitized by Google

by the additional induction due to the cross current-turns. If the armature is Gramme-wound, the lower brush will then need more lead than the upper, and sparking at the lower brush in single-magnet Gramme machines thus frequently arises. This effect is sometimes very marked in machines with cast-iron pole-pieces.

A double-magnet two-pole machine can be made up to a larger size than a single by shaping the pole-pieces so as to throttle the cross induction. A common type of machine is shown in Fig. 2 with the pole-pieces so cut. If it be assumed for the moment that the armature-section current can be reversed with no appreciable field, the largest pole angle that can be used is when the gap induction due to the field excitation is equal and opposite to the cross induction under the leading corner; that is, when

$$\theta = 2\sqrt{[(b\ g\ B_s \times 10)/n\ C\ (r \times \tfrac{1}{4}\ g)]} \quad \ldots\ldots\ldots\ (7)$$

As the armature sections need a sensible field to reverse them, the pole angle must be less than this.

As a convolution passes under a brush its current falls from the normal to zero, and then rises to the normal in the other direction, and the brush leaves the commutator strip just at that instant, else there would be sparking. To find what field the convolution must be passing through to produce this result, the variation of the number of lines of induction through the convolution must be found, and the time of short-circuiting known. Any lines of induction through the convolution must pass, 1st, round by the field magnets, thus taking the same course as the field-magnet induction; 2nd, through the armature and air gap in the same way as the field induction, and then from pole to pole across the external air like the field leakage; 3rd, through the iron of the armature in the immediate vicinity of the conductor, and round the conductor by the air. Fig. 5. In a Gramme armature there are two more paths—4, like 3, only inside the armature ring, and 5, round the ring. The last is neutralised by the reversal of the opposite section, and if an uneven number of sections were used the closed armature circuit would damp it. As to the first, any variation of the induction of the field magnets would be damped by the closed copper field-magnet coils, not to speak of the closed armature coils forming the belt of back ampere-turns. In addition to this, if the current died away, and increased up to its normal in the opposite direction uniformly, the current-turns linked with the circuits 1 and 2 would remain constant, for on one side there is a constant increase of back current-turns, and on the other the reversed or forward turns are again crossing the lines 1 and 2. There could thus only be variation of induction round circuits 1 and 2 if the current in the section did not change uniformly. Any change in the induction round such a circuit as 2 would be damped by the Foucault currents produced in the pole-pieces, as the current is small and the frequency enormous.

The third course—3—may be treated as if the convolution were stretched out straight in air. The self-induction could then be calculated. As half the circuit round the wire is through iron, the self-induction may be doubled. The conductor may be taken as a linear conductor, and the self-induction of the active part taken within reasonable limits. To give some idea of the magnitudes dealt with, we may take, as an example, a drum armature of 15 cm. radius and 38 cm. length, with 120 external conductors, giving 100 volts and 400 amperes at 800 revolutions per minute. Working out the self-induction and resistance of a convolution roughly at $1{,}236 \times 10^{-9}$ and ·000456 ohm, the electromotive force necessary to bring the current to 200 amperes comes out ·274 volt and the field needed to reverse is $B_g = 685$.

The field necessary for the reversal of the current in a section being known, the position of the brushes can be determined.

If the armature had no current the field would fall off very quickly round the armature after emerging from under the pole-pieces. At no load, for instance, the disposition of the lines of induction is, roughly, as shown in Fig. 4. In this case the lines that enter the uncovered part of armature are all cramped together at the pole corners. The lines leaving the shanks of the magnets pass right across and do not enter the armature at all.

If the cross current-turns are alone considered, a disposition, roughly, as shown in Fig. 5, is obtained. There are no lines across, so the lines are cramped together where they leave the armature only. If Figs. 4 and 5 were superposed, the opposite inductions would be equal quite close to the leading pole corners. The exact position would be difficult to determine, but by such a rough method as that just described the position can be found so as to make no sensible error in the calculations. It is clear, then, that except in the case of very small machines, or machines with very light loads, the position of non-sparking of the brushes is close under the leading pole corners.

A glance at actual machines shows that the conclusion here arrived at theoretically—that the brushes are almost under the leading pole corners—is correct. The angle of lead of brushes at full load thus depends on the pole angle, and the back potential, Ω_b, can now be given in the form $(\pi - \theta)\ nC/10$.

Equation (5), for the full-load excitation, can therefore be written,

$$\Omega_{s\text{-}m} = l_a\ B_a/\mu_a + (\pi - \theta)\ n\ C/10 + g\ B_g + l_m\ B_m/\mu_m \ldots (8)$$

Equation (2), for the cross-sectional area of the field magnets, also becomes, in full,

$$A_m = 2ab\ B_a/B_m + r\ [l\ B_a/\mu_a + g\ B_g + (\pi - \theta) n\ C/10]\ /MB_m \quad (9)$$

Probably the greatest problem that still remains for dynamo makers to grapple with is that of lessening or avoiding sparking at the brushes. At present it is necessary to move them whenever the load of the machine is altered. An attendant is therefore necessary if the brushes are to be kept in good order.

As a very weak field is enough to reverse the current in a section, a small pole-piece might be so applied to the armature as to reverse the sections at any convenient place. If the reversal could take place in such a position that the brushes would have a negative lead, the back current-turns would be converted into forward current-turns, and a machine could be designed to give constant electromotive force, or even a higher electromotive force at full load, without any series winding on the magnets at all. Reversing pole-pieces, as they are called, were brought out some two years ago. Fig. 6 shows a simple case. Two reversing pole-pieces are shown. In order that there may be some induction in the same direction as that in the left limb of the magnet, it is clear that the line integral of the magnetic force from A to B must be positive. If the brushes are under these reversing pole-pieces the line A B passes through the neutral points, and the cross potential is $\pi\ n\ C/10$. Each reversing magnet must therefore have

ARMATURE REACTIONS IN DYNAMOS AND MOTORS.

Digitized by Google

$\frac{1}{8}$ *n* C ampere-turns on it to counteract the cross current-turns, and a few more to cause the reversal. In large machines these pole-pieces are thus difficult to work in.

If the reversing pole-piece A is made larger, and attached to the yoke, the same number of current-turns is necessary, as the yoke is at the same magnetic potential as the centre of the armature, if the magnet limbs have equal coils, and the left pole-piece is not highly magnetised.

It is probable that some form of reversing pole-piece will come into general use.

The advantages to be gained by such an arrangement are very great. The brushes do not need to be shifted as the load varies, which saves attendance and wear. Back current-turns are avoided, and this reduces the expense in the series field windings, and saves power now wasted in them. The field magnets can be made smaller, and the induction in them will be the same at full load as at no load, so that the electromotive force will not be unstable at light loads—a state of things which is not always avoidable at present.

Having discussed the theory of dynamos, its application to motors is, of course, exceedingly simple. A motor is nothing but a dynamo running the other way, as a dynamo is a practically reversible machine.

Fig. 7 shows a dynamo armature with the position of the brushes and the back and cross armature windings. For simplicity the brushes are shown as touching the outside of the armature instead of the commutator.

Suppose the direction of the currents in the field and armature to remain the same, but the direction of rotation of the armature to reverse, the dynamo then becomes a motor. The brushes must be inclined the other way, as shown dotted, otherwise the ends would catch in the commutator. The cross and back turns remain as before, so that the armature current opposes the field excitation. It has sometimes been said that the armature current assists the field in a motor, but this can only take place if the brushes are given a negative lead. The same result is obtained in a dynamo by putting the brushes back; but in both cases, of course, this leads to excessive sparking. It is sometimes imagined that some effect of the convolutions being commutated acts differently in a motor, but a glance at the diagram shows that the action is completely reversed. The section being commutated in a dynamo, opposes the movement of the armature; in a motor it assists the armature. No appreciable Foucault currents can be caused by the reversal of the section. If any were, they would assist the dynamo and oppose the motor, so that they would also be reversible.

There is no point in which the dynamo is not perfectly reversible, and there is no foundation for the idea that a motor should have a large armature and a weak field. In so far as any motor departs from the design of a good dynamo it is bad.

Of course the winding of the field magnets in a motor is different.

The winding and design of magnets of motors has received but little attention. Suppose a motor is to run at constant speed on a constant-potential circuit. The shunt excitation is

$$\Omega_s = l_a B_{ao}/\mu_o + g B_{go} + l_m B_{mo}/\mu.$$

At full load the armature induction must be reduced so that the full-load current passes. If E is the terminal electromotive force, and R the armature resistance, the armature induction at full load $B_{af} = B_{ao}(E - CR)/E$, and the gap induction is also reduced in the same proportion. The full-load magnetic potential of the field coils is

$$\Omega_{s+m} = l_a B_{af}/\mu_a + (\pi - \theta)\, n\, C/10 + g B_g + l_m B_m/\mu_m \quad (8)$$

The alteration of the first and last terms makes so little difference to the value of Ω_{m+s} or Ω_s that it may be disregarded. The full-load excitation is thus increased by $(\pi - \theta)\, n\, C/10$, and decreased by the difference between $2\, g\, B_{go}$ and $2\, g\, B_{gf}$. That is to say, extra field excitation is needed to counteract the back current-turns on the armature, and less excitation is needed to produce the reduced air gap induction. If these are equal, the machine will keep constant speed when shunt-wound. In a small or slow machine the armature loss is large; in a large one the back induction is great. A small machine, therefore, needs backward-wound series coils, and a large one forward-wound. If $(\pi - \theta)\, n\, C/10 = 2\, g\, B_{go} - 2\, g\, B_{gf}$, the shunt ampere-turns needed at no load and full load differ only by the difference of excitation needed to magnetise the iron of the field magnets and armature.

As the field induction in a motor is highest at no load, the area of cross section is

$$A = 2\, a\, b\, B_a/B_m + r\Omega_p/MB_m \quad \ldots\ldots\ldots\ldots\ldots\ldots (2)$$

it is thus somewhat smaller than in the case of the corresponding compound-wound dynamo.

As a shunt machine is simpler to make than a compound, and as a differentially wound motor may start backwards, shunt winding is preferable. Within wide limits of size constant-speed motors can be designed with simple shunt winding. All that is needed is to make Ω_b equal to $2\, g\, B_{go} - 2\, g\, B_{gf}$. $\Omega_b = (\pi - \theta)\, n\, C/10$, and $B_g = 2\, a\, b\, B_a\, \pi/(a + d)(r + \frac{1}{2} g)\, \theta$, where d is an allowance for fringe, and θ is also made a little large to allow for fringe. This gives

$$\pi\, \theta - \theta^2 = 20\, a\, b\, B_a\, \pi/(a + d)(r + \tfrac{1}{2} g)\, n\, C \quad \ldots\ldots (10)$$

This appears complicated, but when the symbols are replaced by numbers for an actual machine, of course it is quite simple. It will be found that in very small motors this makes the pole angle too small, while in large machines the pole-pieces would embrace the armature so much as to cause excessive magnetic leakage and reversed induction under the trailing corner, unless the pole-pieces are designed to obviate this.

A properly designed direct-current motor has also the very convenient property of running at approximately constant speed, even if the electromotive force on it varies. If the field and armature are not highly magnetised the armature induction varies approximately as the electromotive force on the shunt. The armature induction, and consequently back electromotive force, of the machine thus varies as the electromotive force on the mains, which is just the condition wanted for constant speed. A direct current motor will therefore preserve approximately constant speed, not only with varying load, but also with varying electromotive force.

This paper has been devoted to direct-current dynamos, as the corresponding treatment of alternating-current machines is hardly ripe for discussion yet, though of enormous importance, as the whole theory of running machines in parallel and of alternating motors depends upon it.

THE SOCIETY OF CHEMICAL INDUSTRY.

MANCHESTER SECTION.

On the 4th inst. two papers were read by Mr. W. Younger, F.C.S., the first being on the "Reduction of Arsenic Acid by Hydrochloric Acid." The author has used this reaction for estimating arsenic in various compounds as follows:—Potassium iodide and hydrochloric acid are added to a solution of arsenic acid; arsenious acid is produced, and iodine is liberated in an amount directly proportional to the reduction. The solution is then boiled, neutralised with sodium bicarbonate, and titrated with iodine and thiosulphate. This method gives results comparable with the sulphurous acid method, and by its use very small quantities of arsenic can be easily estimated—*e.g.*, ·0187 per cent. arsenic in oil of vitriol. Various experiments to prove the accuracy of the reaction have been made.

In a short discussion which followed the reading of the paper, Dr. G. H. Bailey said that, although the application of the reaction to the estimation of arsenic might be new, yet the principle involved had long since been described by Bunsen and Fresenius, and had been generally employed in the laboratory.

The second paper, which was on the "Analysis of Deacon Gases," was a short addition to a previous paper by the author. The gases produced in the Deacon chlorine process consist of chlorine, hydrochloric acid, nitrogen, air, and aqueous vapour. The first paper referred especially to the detection and estimation of small quantities of hydrochloric acid in the presence of chlorine. In the present paper the author gives a method for the complete analysis of the gases. He absorbs the moisture in strong sulphuric acid, the chlorine and hydrochloric acid in an arsenious acid solution, the oxygen (which is calculated to air) in cuprous chloride, and obtains the nitrogen by difference. The aspiration of the gases from the decomposer is accomplished by the graduated cubic box figured in the first paper.

After the above papers some discussion arose with respect to the Technical Instruction Act, 1889, but it was decided that a full discussion on this subject should be postponed to the next evening.

NEWCASTLE SECTION.

At a meeting of this section, on the 6th inst., Mr. Shaw drew attention to the formation of sulphate of copper in the copper flues of gas stoves; and Mr. Lovibond stated that he had noticed an encrustation of the same salt in a brewer's copper which had burnt through in less than two years owing to the use of an inferior coal containing much sulphur.

Mr. Morrison read a paper on "Personal Recollections of the Bachêt Soda Process." An experimental plant was set up at the salt works at Walker-on-Tyne to work out on a practical scale Bachêt's process for the manufacture of caustic soda by the decomposition of salt with litharge, the litharge being regenerated with lime. Owing to the enormous bulk of water which had to be employed, as well as the large quantity of costly litharge in proportion to the almost minute amount of caustic obtained, the experiment proved a failure, as under favourable conditions the cost of production was too great.

Notes.

CHINESE DEFENCES.

Whatever vacillation the Chinese may seem to show in the matter of railway development, there can be no doubt that they follow with unswerving resolution their plans for coast defence, for which they always seem to be able to find money when it is wanted. We learn that they have recently placed with Krupp, of Essen, an order to the amount of £250,000 for guns for the defence of the Veiho. They have almost as much competition for their favours from the makers of guns as they have from the financiers who wish to do themselves the honour of lending them money, but the representative of Herr Krupp is credited with an unusual amount of energy and tact, which seems to carry the day. Not only the coast defences, but also the navy, is receiving attention, and Admiral Lang has brought it to a wonderful state of efficiency, considering the difficulties he has had to overcome. It is further reported that an order has been sent to this country for a considerable amount of machinery and other appliances for the manufacture of steel rails, and we think it will be found, as we have often pointed out that there is considerable method in what seems to be the obstructive methods of the Chinese. They no doubt recognise the advantages of Western industries, but they have their own ideas as to the methods by which they should be introduced into their country, and their policy is to place themselves in a position to withstand foreign aggression, and to allow the industrial and commercial changes to be brought about slowly, no doubt with a considerable amount of foreign assistance, but at the same time largely by the development of their own resources.

MACFARLANE'S FACILEGRAPH.

This ingenious appliance for the engineer's desk is intended to replace the somewhat expensive ruled paper for scale drawings and diagrams. The principle of it is extremely simple. The leaves of the book are semi-transparent, and behind these is placed, when in use, a card, upon which thick black lines are rules. The lines on the card may indicate any desired scale, or adopt any angle or curve. Drawings to any scale may thus readily be made. The publishers intimate that they can supply cards with any desired arrangement of scales, lines, and curves, provided a sufficient quantity be ordered. The Facilegraph must be of great use to the engineering student for work both at home and in class, and also to the engineer in ordinary practice.

THE PROPOSED FORTH AND CLYDE CANAL.

The promoters of both the Loch Lomond and the direct route schemes are displaying considerable energy in their prosecution of them. The former had a meeting in Edinburgh recently, at which arrangements were made for bringing their plans prominently before the public. The latter have instructed Messrs. Crouch & Hogg, civil engineers, Glasgow, to make a survey of the route and report to them, so that we ought soon to be in a position to discuss both plans on their merits. In the meantime, however, Mr. William Smith is energetically bringing his plans for a ship railway before various public bodies, and they have been very favourably received. The great argument put forward in favour of the Loch Lomond route has been that it is the only one suitable for ships of war, but a letter has just been received from the Secretary for Scotland, in which it is stated that, after having consulted with the naval and military authorities, the Prime Minister and the Secretary for Scotland are of opinion that her Majesty's Government would not be justified in incurring financial responsibility in regard to the proposed undertaking. This may only mean that public opinion has not yet been brought sufficiently to bear on the Government, but at any rate it shows that at present the schemes must be discussed chiefly on their commercial merits.

THE END OF THE GAS STOKERS' STRIKE.

After a duration of two months the dispute between the gas workers, coal porters and the South Metropolitan Gas Company came to an end last week, and we must confess to a considerable amount of disappointment over the whole affair. The men claim that they are going back perfectly unfettered by the bonus agreement, and that the removal of this obnoxious obligation is highly satisfactory to them. At the time the bonus system was proposed we pointed out some of its objectionable features, and we hoped that when these had been removed that it would have been adopted in a modified form, but the men evidently prefer to trust to their trades unions for the improvement of their position rather to any scheme which seems to them to fetter their liberty and place them more completely in the hands of the employers. They ought, however, to remember that every form of partnership lessens to a certain extent the liberty of the partners, but it ought to strengthen their confidence in their good intentions, and they should try to make arrangements which will bring them and the employers into closer relations, and so prevent disputes of all kinds. A social and industrial partnership is a higher ideal to aim at than the raising up of two opposing forces ready to do battle whenever an opportunity is offered of the one overcoming the other. It has been arranged that, except where mutually agreed the Company is to revert to the eight hours system as in operation previous to the strike instead of the longer hours now worked. As, however, many of the new men prefer the two shifts system, because it gives them longer intervals of rest, some of the stations will be worked on that system. Although the struggle has ended in a *fiasco*, we trust that it will at least have taught both parties the necessity for mutual forbearance, and for at least intelligent discussion of differences before force is resorted to.

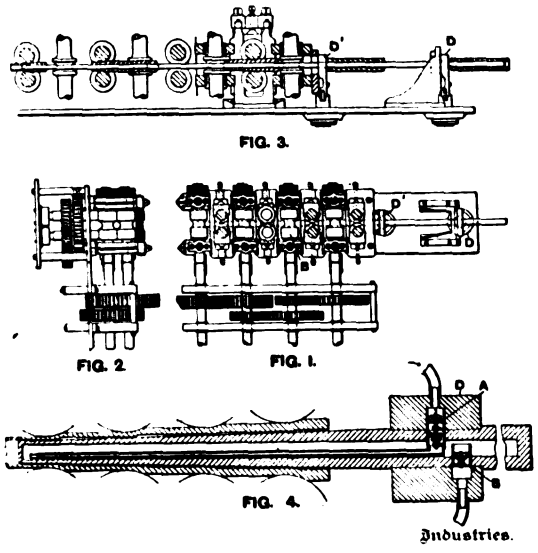
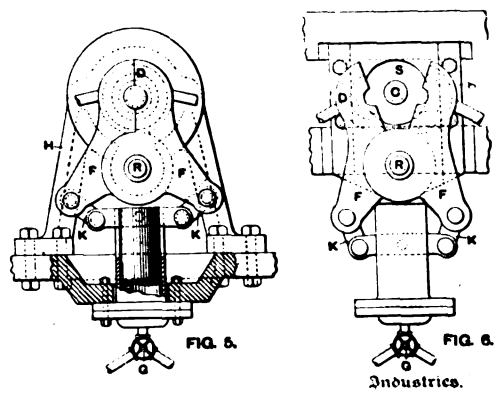
ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.



ENGINEERING.

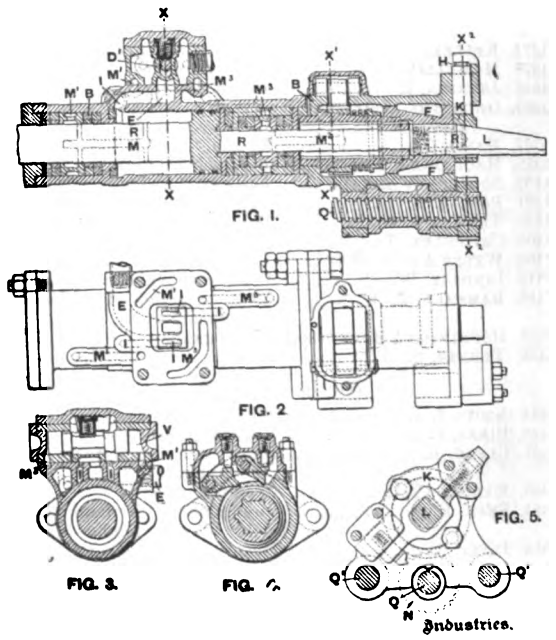
CARDING ENGINES.—*J. M. Hetherington, Manchester.*—The object of this invention is to render more perfect the enclosure of the main carding cylinder at the breast or part of the engine which extends from the "taker in" cylinder to the chain of flats, the intention being to prevent the escape of air, and, as a consequence, of dirt and fibres. To obviate this defect, a curved shield is employed, which extends outwards from the aforesaid breast cover, and partly around the flats which are upon the carrying wheels, the inner and preferably beveled edge of the shield being either in close contact with the upper edge of the breast cover, or being separated by as little space as desired. The shield is suspended from the brackets supporting the carrier wheel in such a manner as to permit of adjustment towards the axis of the carrier wheel and the breast cover. Two claims are made.—No. 3913. March 6th, 1889. 6*d*.



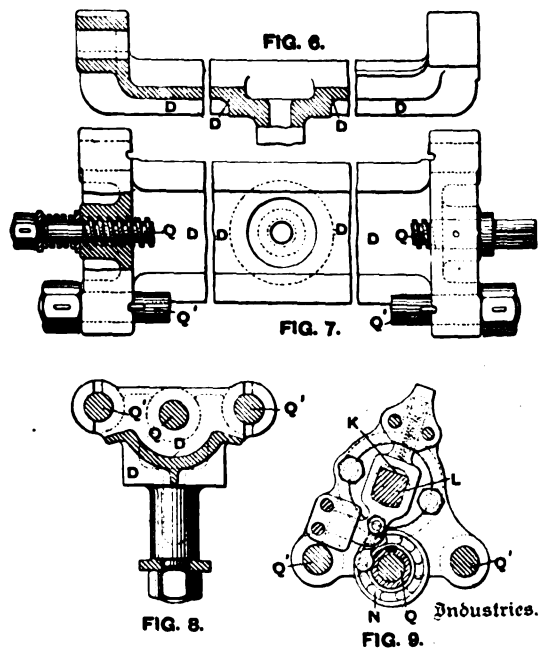
STEAM HAMMERS.—*J. A. Facer, Germantown, U.S.A.*—The invention refers to the use of steam hammers for the purpose of forming wheels for cars. The object is to make a finished wheel from a solid bloom or ingot of steel by forging the ingot under heavy steam hammers having suitably shaped dies. The car wheel made in this manner is compact and homogeneous as to metal, and possesses a hardened surface due to the forging. Further details of the invention may be gathered from the claims. Claims: (1) In a steam hammer for forging wheels, the combination of the hammer die and anvil die having recessed surfaces corresponding to the shape of the sides of the finished wheel, a projection upon one side of said hammer die and supporting devices to support the blank in an upright position against the vertical face of the anvil die and under the projection on the hammer die; (2) in a steam hammer for forging wheels the combination of a hammer and an anvil die having their surfaces formed to correspond to the shape of the finished wheel when the dies are in contact, a projection carried by said hammer die and supporting devices to support the blank in an upright position under the said projection; (3) dies for forging steel wheels consisting of the combination of an anvil die having a large depression or recessed portion upon its face adapted to receive the entire wheel blank including the flange, in combination with a hammer die formed with a small depression upon its face corresponding only to the side of the wheel and corresponding with the recessed portion in the anvil die to shape the blank into a finished wheel, and provided on its front part with a projecting hammer part arranged above the support on the anvil die and shaped to correspond to the tread and flange of the wheel; (4) dies for forging steel wheels consisting of the combination of an anvil die having a large depression or recessed portion upon its face adapted to receive the entire wheel blank including the flange, and a support in front and at a lower level than its face and formed to correspond to the tread of the wheel, including a groove for the flange, and also with a lateral support for the wheel when resting upon the front supports, and removable pin or part detachably connected with the anvil die opposite to the lateral support to hold the wheel blank in position while being turned, in combination with a hammer die formed with a small depression upon its face corresponding only to the side of the wheel and corresponding with the recessed portion in the anvil die to shape the blank into a finished wheel.—No. 17109. October 29th, 1889. 8*d*.

GAS ENGINES.—*H. Williams, Stockport.*—The improvements are particularly applicable to the "Stockport" type of gas engines with cylinders arranged tandem on opposite sides of the crank shaft and they are to ensure the delivery of a full charge of explosive mixture from the compression to the power cylinders. The compression cylinders are situated immediately below each of the power cylinders. The ends of the two power piston rods are fitted together to form a crosshead through which the crank-pin passes. According to the invention the crosshead is formed with a downward projection which carries a stud constituting a crank-pin for a connecting rod secured to the piston of one of the compression cylinders. This compression cylinder piston is adjustably connected to the other, so that the movements of both are simultaneous. By driving the piston of one compression cylinder from a separate and independent crank-pin as described a longer stroke can be given to it than that of the power piston, so that after the power piston has finished its instroke the compression piston below still continues to move inward and drives a full charge of gas and air into the power cylinder. Claims: (1) In a double-acting gas motor engine of the type specified, the combination with the power cylinders, their pistons and rods connected by a crosshead to the crank-shaft, of a separate and independent crank-pin carried by a projection from said crosshead, said crank-pin being connected to and operating the respective pistons of the compression cylinders as described and for the purpose specified; (2) refers particularly to appliance as shown in the drawings of specification.—No, 3820. March 5th, 1889. 6*d*.

ROLLING SEAMLESS TUBES.—*W. P. Thompson, Liverpool.* (*C. Kellogg, Findley, U.S.A.*)—The inventor describes an appliance for rolling seamless tubes from hollow steel ingots. The machine consists of a series of pairs of suitably shaped rolls, each successive pair being driven at a greater speed than the preceding pair, and a tapered or conical mandril placed between the series of rolls. Means are provided for placing the ingots on the mandril whilst others are being rolled, thus making the working of the machine continuous. In the accompanying drawings, Fig. 1 is a plan of the machine; Fig. 2, an end elevation; Fig. 3, a sectional elevation of the machine showing the operation of feeding and reducing a series of ingots simultaneously; Fig. 4 is a horizontal section



taken longitudinally through the mandril, showing the means of controlling a flow of water to the hollow mandril to cool it, and also showing the gradual reduction of an ingot; Fig. 5 shows an enlarged elevation view of the grip D for holding the mandril in place—the grip is here shown closed; Fig. 6 shows a similar grip D^1 opened. The grips are opened one at a time as is shown in Fig. 3 to pass the ingots on the mandril. They are held closed by a pressure of fluid acting upon the bottom of the piston which is connected to the arms F by the links K. To open the grips, the pressure is removed from the piston by a three-way valve G,



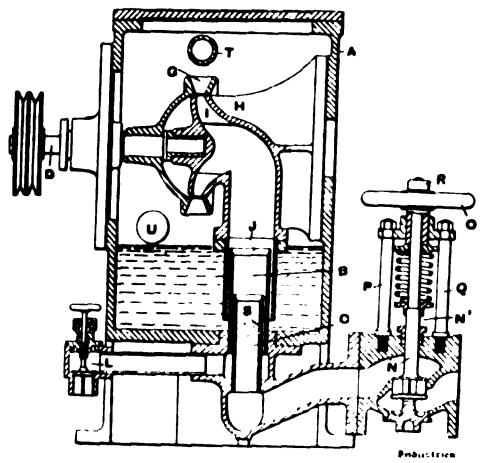
and the jaws then drop open. The jaws of the grips are made to close into grooves in the mandril. The mandril is made tapered, so that the resistance between the mandril and ingot only takes place at the points where the rollers act. The rollers are shown, each pair with their axes at right angles to the preceding pair, the object being to reduce the tube uniformly. The cooling water is passed into the mandril through check valves A and B situated in the grip D. These check valves open and close automatically as the grip is opened and closed. Eight claims are made for the form of tube rolling machine described and the details.—No. 2933. February 19th, 1889. 8*d*.

RAILWAY TRACKS.—*J. H. Clarke, Glenmary, U.S.A.*—The track described in this specification is constructed entirely of iron, and is self-supporting, the usual cross-ties and small fastenings being dispensed with. The chairs for the rails are made to cover a large surface, and are hollowed on the underside. The rail is supported centrally upon the chairs and the inner edge of the foot of the rails is held by an overlapping lug or lip of the chair. A bar of metal is placed between each pair of chairs to keep them at the proper distance according to the width of the track. To this distance bar are bolted hooks which pass under the rail upon each side of the chairs, and grip the outside edges of the foot of the rails. The hooks constitute with the lug upon the chairs a firm grip for the rails, whilst the distance bar prevents the chairs coming closer together and the hooks prevent them spreading. The chairs are constructed with their inner deflected edges longer than the outer, so that as they bed themselves, due to weight upon the rails, the gripping device tightens. The chairs may be circular and their undersides concave or pan-like, or they may be straight on their undersides with oblique anchoring lugs to enter the soil. Seven claims are made.—No. 18053. November 12th, 1889. 6*d*.

PERCUSSIVE ROCK DRILLS.—*A. W. Daws & T. W. Daws, Laurvig, Norway.*—Improvements are here introduced into a machine drill described in a former specification, No. 10738, 1887. They consist of—1st, an improved arrangement of the passages formed in the piston rod for the purpose of actuating the valve of the cylinder; 2nd, of an arrangement of parts enabling the same machine to be fitted to different sized saddles; 3rd, of an improved feed for advancing the drill; and 4th, an improved block or bearing for fixing or combining the rotating gear and feed gear of the drill. Referring to the figures, Fig. 1 is a longitudinal section of the drill; Fig. 2, a plan; Figs. 3, 4, and 5, sections upon the lines X X,

X^1 X^1, and X^2 X^2 respectively; Figs. 6, 7, and 8, elevations and plan of the drill saddle; and Fig. 9, a modified form of Fig. 5. In carrying out the first improvement, the passages M M^2 in the piston rod R are made of such length that one end of each is outside the stuffing boxes B when the other end is in communication with one of the ports M^1 M^2 of the valve cylinder V. This enables the motive fluid to be exhausted from the valve cylinder with certainty at the time motive fluid is admitted at the opposite end. The improved saddle is shown in Figs. 6, 7, and 8. A cast metal bracket D supports two guide rods Q^1, upon which the drill casing slides, as shown in Fig. 9. The feed screw Q is arranged between the guide bars Q^1 and is automatically worked forward

by the lifter L, raising the frame K and with it the spring catch which engages in the notches of the wheel N. The lifter L is connected to the piston rod R by a swivel joint to permit the latter turning. Another construction of this movement is shown in Fig. 5. The fourth improvement consists in the method of providing a bearing for the rifled bush Y of the rotating gear in the block F. The block F in its longitudinal section has the form of a cone, except the ends, which are circular plates. The circular ends are to fit the drill casing. The block F also acts as the guide for the lifter L and end of the piston rod R. Six claims are made for the improvements described.—No. 3691. March 2nd, 1889. 8*d*.



PILING WROUGHT-IRON PUDDLE BARS.—*R. P. Gubbins, London.*—The invention relates to improvements in piling or preparing the puddle bar previously to its being reheated and rolled into finished iron, and is performed as follows:—The bars

Digitized by Google

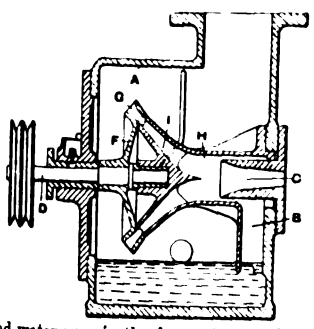
are indented whilst hot by passing between suitable rolls, in such a manner that they are nearly cut in two upon opposite sides and at regular intervals apart. The effect of this almost cutting the bar in two on opposite sides is, that it readily assumes a zigzag form, and can, upon applying pressure to it in the direction of its length, be easily and speedily folded together, taking the form of an ordinary puddle bar pile. If there are too many folds or layers in it, some of them may be easily removed, as they are attached to each other by a very slight connection; if the pile be too small, a piece or two more may be laid on top of the folded ones in the usual way, and thus piles of any weight formed. The folded pile being hot and immediately put in the reheating furnace, a great saving of heat follows the use of this system. The rolls for making the indentations in the bars are of such width apart as to pass the pile-bar without elongating it much. In the surface of the rolls are fixed knives such that as the bar passes between the rolls it is cut nearly through at regular intervals but from opposite sides. Claims: (1) The combination of the "piling rolls" and the knives fixed to the "piling rolls," for cutting almost in two the puddle bar at regular intervals apart on opposite sides as described; (2) the process of folding a puddle bar into a compact mass, ready to be reheated as described; (3) as an article of manufacture the folded pile.—No. 16109. October 12th, 1889. 6*d*.

Turbines.—*N. W. Curtis & A. E. Carey, London.*—The object of this invention is to simplify centrifugal apparatus worked by fluids. The illustrations show in Fig. 1 a section upon the side elevation; Fig 3, a section upon the parts F H; and Fig. 2, a section upon a modification of the apparatus. In the case A is mounted the spindle D which carries the piece F with vanes G. Projecting into the piece F is a part H with vanes I

FIG. 1.

curved in contrary direction to those in the piece F. The part H supports one end of the spindle D, and it has at its base three pipes J, B, and C, in communication with water, air, and steam supplies. The pipe C is in communication with the steam valve N, the pipe B with an air valve L, and the pipe J in communication with the water supply in the tank. The action of the apparatus is as follows:—The hand wheel O is turned until the spring P is so far compressed as to force the valve N from its seat against the steam pressure at the back. Steam then flows through the pipe C into the pipe B and draws water at a high temperature through openings S in the tube B. The mixed steam

FIG. 2.



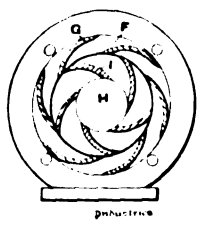


FIG. 3.

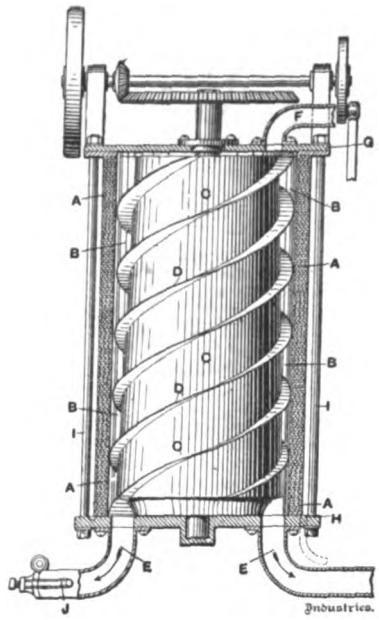

and water pass in the form of spray into the pipe J, and a further supply of water is drawn up between the pipes J and B, the whole being impelled past the vanes I of the case against the vanes G of the disc or wheel F, causing the disc or wheel and its shaft D to revolve. The water in the case A is kept at the requisite temperature by means of a regulated inflow at T and outflow at U. The spring P acts as a regulator on the valve N to control the passage of steam to the apparatus. In the modified form shown in Fig. 3 a single jet pipe C is used and water suction pipe B. Claims: (1) Apparatus for obtaining motive power by the action of a mixture of steam and water in the form of spray; (2) apparatus for obtaining motive power consisting of a disc and case provided with vanes and steam and water supply ways; (3) stop valves combined with screw and spring gear.—No. 1862. February 2nd, 1889. 6*d*.

Screw Conveyer.—*L. Hopcraft, London.*—The conveyer is designed to convey coal and other material in any desired direction instead of in a straight line as hitherto. According to the invention the screw conveyer is constructed in sections, each section carrying a part of the helical blade. These sections are mounted loosely upon a non-rotatable rod curved to the shape of the direction in which it is desired to convey the coal or other material. Between each two sections is placed a gimbal or universal joint, provided with two pairs of trunnions, each pair at right angles to the other pair. One pair of trunnions take into recesses or bearing in one section, and the other pair of trunnions into bearings in the next section. A hole is made in the gimbal joint for the passage of the non-rotatable rod. By this system of connecting the different sections to each other, a continuous helical blade is formed, and the whole of the sections rotated together. Claims: (1) The construction of a screw conveyer in sections fitted together by gimbals or universal joints working upon a central rod bent to the required shape, in the manner described; (2) a feed regulating device, consisting of a cone with a prolonged wing or blade mounted upon the non-rotatable shaft, and having a thread working in a corresponding groove of the same pitch as the blade to adjust the position of the cone beneath the supply pipe, to regulate the supply; (3) the improved screw conveyer constructed, combined, and operating as described.—No. 2581. February 13th, 1889. 8*d*.

Steam Engines.—*R. H. Edgerton, Philadelphia, U.S.A.*—In this engine the piston has a combined or simultaneous reciprocating and rotary movement for imparting motion to a driving shaft without the intervention of crossheads, pitmans, or cranks. The piston is mounted loosely upon its rod which passes through both ends of the cylinder and constitutes the motor shaft. The piston rod is connected to the piston by a feather so that the rotation of latter about its axis cause the former to rotate with it. In the surface of the piston, which is made of great length, is cut a groove, the course of the groove being elliptical. In this groove works a pin firmly fixed to inside of the cylinder at its centre. As the piston is forced from end to end of the cylinder the pin travels in the groove of the piston and causes the piston to revolve. Disc-shaped valves are situated at each end of the cylinder for the admission and exhaustion of the working fluid. They are attached to the piston rod with which they revolve. Seventeen claims are made for the engine described.—No. 18996. November 26th, 1889. 8*d*.

Separating Solids from Liquids.—*F. H. Danchell, Maidstone.*—In apparatus at present in use the process of separation of the solids from the liquid is not continuous; but in the apparatus described in this invention the process is made continuous and much time saved. The illustration shows a vertical section of the machine. A A show a series of rings in close proximity to each other each ring consisting of an annulus of metal flat in cross section and of shallow depth, interstices between the adjacent rings forming the channels of escape for the liquid. The mixture to be separated is passed in by the pipe F. The solid matters are retained in the space B formed between the walls of the inner barrel C and the pile of rings A. These solid matters are carried by the helical blades D down the spaces B towards the

outlets E E to be conveyed away. The space B is of diminishing area from the uppermost part to the lower portion owing to the barrel C being formed of increasing diameter from top to bottom. The rings A are held firmly together by plates G H and bolts I. The apparatus is revolved by suitable gearing shown at the top of the machine. The outlets for the solid matters are fitted with valves J, which retain them until sufficient pressure has been brought to bear on them by the helical blades D to remove all the liquid. Claims: (1) The employment as filtering media of plates of metal of annular or equivalent form, held superposed in series one upon the other, and kept in close proximity to each other, the small interstices between the adjacent plates forming channels of escape for the liquid, but preventives to the passage of more solid matters; (2) in apparatus for separating solid matters from liquids, a series of plates held superposed in close proximity to each other, the small interstices between the adjacent plates forming channels of escape for the liquid, but preventives to the passage of more solid matters, in combination with means—as the helical screwed barrel C D—for conveying away the solid matters as they are separated, and means for supporting, containing, and driving the same; (3) the general arrangement and combination of parts forming apparatus for separating solid matters from liquids by the aid of a series of plates held in close proximity to each other, the small interstices between the adjacent plates forming channels of escape for liquid, but preventives to the passage of the more solid matters.—No. 499. January 10th, 1889. 8*d*.

Gas Motors.—*A. J. Boult, London. (E. Capitaine, Berlin.)*—The invention relates to the distributing mechanism for gas motors, and its object is to enable the toothed wheel ordinarily employed to be replaced by a crank or an eccentric. For the purpose of operating the valves at each alternate revolution only an arm is pivoted to the eccentric rod to alternately strike and miss the valve rod. To this arm is pivoted a plate in the shape of a cross, having a spring bearing to form a resistance to any change of position relative to the arm. The arms of this plate are approximately at right angles to the axis of the valve and eccentric rods, and tends to be held in this position by two springs attached to the cylinder. The operation is as follows: When the arm pivoted to the eccentric rod strikes the valve rod and thus shifts the valve, one arm of the cross-shaped plate strikes, in its movement forward with the arm, a pin upon the cylinder. The plate is thereby moved out of its normal position relative to the arm, and its top end displaces one of the springs attached to the cylinder. At the end of the return stroke when the arm moves away from the end of the valve rod, the spring upon the cylinder thrusts the arm aside by reason of the plate's spring joint holding the plate in its displaced position. In the next stroke forward the other arm of the plate strikes a second pin on the cylinder and makes the plate assume its normal position so that it will strike the valve rod the next stroke. Two claims are made.—No. 121. January 3rd, 1889. 8*d*.

Manufacture of Tuyeres.—*W. Webster, Sheffield.*—The tuyeres to which this invention particularly refers are such as are used for conveying the blast to Bessemer converting vessels An improvement is made in the machines for the manufacture of these articles by perforating them at the time of moulding. In the illustrations given, Fig. 1 is an elevation partly in section of a complete machine, Fig. 2 shows two completed tuyeres in the act of being removed from the machine, Figs. 3 and 4 show a completed tuyere, and Fig. 5 shows a horizontal section of the machine upon the line X X. C is the cylindrical press containing the plastic material for making the tuyeres. At the bottom of the chest C are two apertures leading into the moulds B B

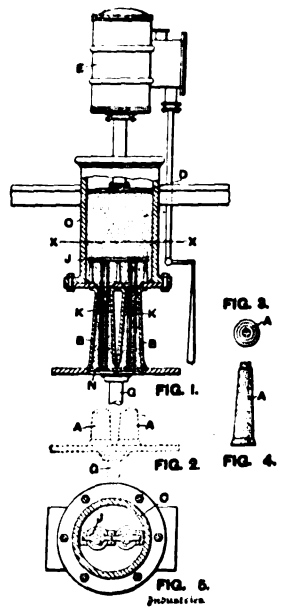

FIG. 3.

FIG. 1.

FIG. 4.

FIG. 2.

FIG. 5.

in which the tuyeres are formed. Rods K K are suspended from a cross-bar J, and pass down through the apertures and the moulds B B to holes in the plate N, which keeps them in their proper position during the moulding. The plate N can be lowered from the moulds by the rod G to remove the tuyeres, as shown in Fig. 2; parts of the tuyeres there shown are broken away. The plastic material is pressed down into the moulds and around the rods by the piston D, actuated by steam or hydraulic power in the cylinder E. When the moulds are filled, the table with the tuyeres is lowered, and the tops of the tuyeres cut off either by hand or automatically. The core rods may be fixed to the plate N instead of the crosshead as described. Claims: In machinery and appliances for the manufacture of tuyeres made from refractory material in a plastic state, the arrangement and combination of parts and appliances by means of which such tuyeres may be produced either by hand or power, so that the perforations or holes are formed therein during the operation of moulding, and when a tuyere so made is ejected from the mould, and cut off to the required length and lifted off the table, it is complete and ready for drying and baking.—No. 3096. February 21st, 1889. 8*d*.

Cutting Metals.—*B. C. Tilgman, Philadelphia.*—The cutting and abrading of metals is assisted in this invention by the application of electricity to fuse or soften the part of metal operated upon. In the practical application of the invention an electric current is used of large quantity but low intensity. The metal object to be operated upon forms one electrode, while the other (preferably the cutting tool) is made to come in contact with the metal object at the point where the mechanical cutting action is taking place. The passage of the current from one electrode to the other at the point of contact, which is also the point of maximum electrical resistance, softens or fuses the metal at that point. When the tool itself constitutes an electrode, it is preferably made similar to a milling cutter to avoid heating of its cutting part. The different teeth are brought then into action with rapid succession. The whole operation can be performed under water, or the tool and work artificially cooled. Claims: (1) The process of cutting and abrading metals, which consists in heating by an electric current successive small portions of the metal surface and simultaneously removing the heated metal by an abrading tool; (2) the process of cutting or abrading metals which consists in passing a current of electricity through the successive points of contact of the metal being treated and the abrading tools; (3) the process of cutting or abrading metals which consists in passing a current of electricity through the successive points of contact of the metal being treated and a rotating abrading tool.—No. 19869. December 10th, 1889. 8*d*.

Pulveriser.—*T. R. Jordan, London.*—The pulveriser is designed for crushing ores and such like substances. The main object of the invention is to simplify the construction and reduce the wear and tear of the parts; also to make the wearing surfaces easily removable. The apparatus comprises a receptacle or pan which is provided with a circular crushing path, and is arranged to be rotated about an inclined axis. In this pan are placed heavy spherical mullers or balls, which, by the rotation of

Digitized by Google

the pan, are caused to roll and revolve about their axes on the said crushing path, the inclined position of the pan keeping them practically in the same position in the lower part of the pan. The ore or other substances is fed into the pan, which is open at the top, and after undergoing the action of the balls passes through a meshed surface of the pan. The meshed surface is conical, in the central part of the pan, so that as it assumes the highest position in the rotation of the pan it becomes level with the bottom of the crushing surface, and the material flows over it. Provision is made for the introduction into the pan of a jet of water, which is so regulated and directed as to wash the crushed or pulverised material over the meshed surface and cause the smaller particles to fall through and be conveyed away. Seven claims are made.—No. 3,298. February 23rd, 1889. 11*d.*

SCREW PROPELLERS.—*C. Inwood, Gravesend.*—The object of this invention is to reduce the slip or difference between the linear advance of the vessel propelled and that of the screw propeller due to its pitch, and the formation of the blades in such a manner that they shall be of great strength and rigidity in combination with lightness, and the whole of their surface effective for propulsion. The blades are made of sheet metal of the same gauge from the tip to the root. The blades are U-shaped, and each one joins the boss at two places, parallel to each other and of a given pitch, and arranged round each end of the boss equidistant from each other. Claims: (1) The construction of screw propeller blades with helical propelling surfaces in combination with the propeller boss forming a figure after the manner of an open triangle or U; (2) the construction of propeller blades with two roots, each joining opposite ends of the boss, helically deposed and arranged that no portion shall overlap that of another in line with the axis of rotation or advance.—No. 18431. November 19th, 1889. 6*d.*

BOILER FURNACES.—*E. Hales, Philadelphia, U.S.A.*—In the illustrations, Fig. 1 is a front elevation of the furnace, Fig. 2 a section upon the side elevation, A is the container for the fuel, which is fed in at the top and descends by gravity to the bottom. In the bottom part of the container A are openings C and N; the bottom itself is entirely open, and the fuel rests upon the accumulated ashes F. Air for combustion is supplied through the opening E, closed at will by the suspended door K. The air passes through the fuel in the lower part of the container A, and forms combustion. The products thus formed are conducted on by the draught into the flue B beneath the boiler D. To allow fresh fuel to descend the ashes are cleared away from under the fuel gradually. Claims: (1) The method herein described of

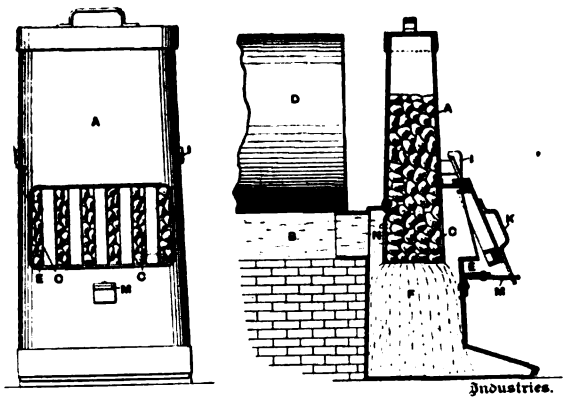

FIG. 1. FIG. 2.

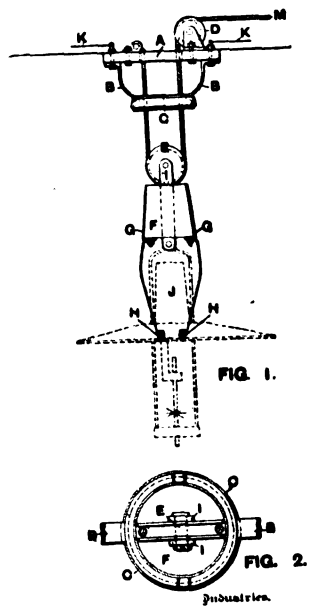


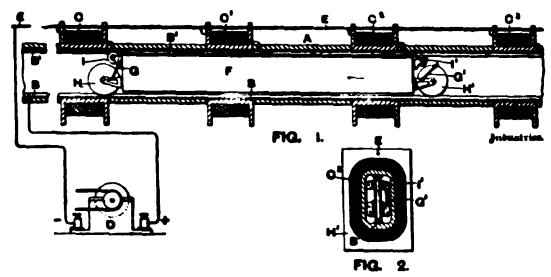
burning fuel in furnaces for steam boilers and other purposes, which consists in storing and feeding the fuel in a vertical chamber having grated side openings, supporting from lateral displacement the burning fuel, and the fuel to be burned on a bed or bank of ashes in the lower portion of the furnace, igniting the fuel lying between the grated side openings, and drawing off the products of combustion, and supplying the air which supports combustion, at right angles to the vertical body of the furnace; (2) a grateless furnace for steam boilers and other purposes, consisting of a vertical chamber, in which the fuel being burned is supported by a bed of ashes in the lower portion of a vertical chamber; (3) a grateless furnace for steam boilers and other purposes, consisting of a vertical chamber, in which the fuel being burned and the fuel to be burned is supported by a bed of ashes in the lower portion of the vertical chamber; and (4), (5), (6), (7), referring more particularly to the parts as illustrated.—No. 18502. November 19th, 1889. 8*d.*

SHEDDING MECHANISM OF LOOMS.—*T. A. Hinchliffe, Denby Dale, & R. Ross, Bradford.*—Improvements are here made in "Howles" and similar shedding mechanism of looms in which motion is communicated from the jack levers to the healds by means of leather straps passing over or under guide pulleys. The improvements consist in replacing the leather straps by suitable chains, particularly to those parts exposed to excessive wear. This overcomes the disadvantage experienced in practice of the rapid wear and stretching of the straps. The chains are formed with flat links adapted to pass smoothly over the guide pulleys. Claim: The combination with a shedding motion of a loom of a chain or chains adapted to pass round a pulley or pulleys, and transmit motion from the jack levers to the healds as described.—No. 2186. February 7th, 1889. 6*d.*

CONDENSERS.—*D. Halpin, London.*—The condensation is conducted by bringing the steam into intimate contact with a current of air. The exhaust steam is caused to escape through a nozzle that is presented to the air-inlet orifice of a rotary fan, so that both the exhaust steam and a current of air are drawn into the centre of the fan. This combined current of air and steam is caught up by the rapidly revolving blades of the fan and thoroughly intermixed as it passes to the periphery of the fan, so that by the time it reaches that point the steam is condensed and the resulting water of condensation thrown to the sides of the fan casing, where it is collected and led away, whilst the blast of air can be utilised for other purposes. A lining of wire gauze or other suitable material is provided at the periphery of the fan to catch up and retain the water thrown against it by the fan blades. The fan is preferably specially constructed, and a second one can be employed to condense any steam that should escape the first operation. The mixture of air, water, spray, and any uncondensed steam might also be made to pass from the fan into a chamber containing groups of tubes so arranged that the mixed current is first made to pass transversely against the outer surfaces of the tubes, on which that portion of the water already condensed would be collected, and flow downwards into a receptacle, while the air and any uncondensed steam is made to flow through the tubes so as to condense the remainder of the steam held in suspension. Claims: (1) The herein-described method of condensing exhaust or waste steam by intimately mixing its current with an air current from which the water of condensation afterwards separates; (2) for effecting admixture of steam and air currents for the purpose above referred to, a propelling apparatus or fan arranged and operating as described.—No. 4340. March 12th, 1889. 8*d.*

ELECTRICITY.

SWITCHES FOR SUSPENDED ARC LAMPS.—*F. Wagg & W. Hudson, London.*—The switch is constructed to automatically "cut out" a lamp by simply lowering it, and to dispense with the usual slack wires, &c., that constitute the "leads." Referring to the figures, A is a disc of wood or non-conducting material permanently fixed in the position from which the lamp is to be hung. Bolted to the block A are springs B B for supporting a split ring C, which is surrounded by an elastic closing band. The lamp is fastened to strips of metal I which support the pulley E and a tapered block of non-conducting material F. A rope



passes around the pulley E and a pulley D for raising and lowering the lamp. Strips of metal G G are attached to the block F and electrically connected to the terminals H H of the lamp. The springs B are also electrically connected to the main "leads" K K. In the position shown in Fig. 1 the lamp is lowered and is "cut out" of current, and the current passing uninterrupted through the ring C. By raising the lamp by the rope M the wedge F will pass into and separate the ring C, and put the strips G in contact with the separated parts of the ring, and so pass the current through the lamp. Claims: (1) The method and arrangement described; (2) the absolute safety from electric shock directly the lamp is lowered, forming its own "cut out;" (3) the taper plug, with insulated strips and split ring, with connecting springs and india-rubber band, forming a switch in the manner described; (4) the application of the switch arrangement to either "parallel" or "series" system of lighting; (5) the arrangement by which the lamp is raised and lowered, and prevented from twisting and preventing the polarity of the carbons.—No. 2742. February 16th, 1889. 6*d.*

ELECTRIC METERS.—*W. P. Thompson, Liverpool.* (*H. C. Tudor, Rosport, Luxemburg*).—In electric meters whose motive apparatus is either a clock motion or an electrical one derived from the distributing circuit in which the apparatus is placed, the motors must be very regular in their action if the periods during which the intensity of the current is to be registered are to follow each other at regular intervals. The object of this invention is, first, to regulate the motion by making it dependent on the motion of a governing apparatus, and, secondly, to abolish the necessity of periodical winding. The governing apparatus preferably used at centres of distribution is composed of a pendulum which establishes and interrupts at intervals the source of electrical energy supplying the motive apparatus of the meters. The motive apparatus of each meter consists of a simple ratchet wheel governed and actuated by a hooked lever. The lever is worked by the armature of an electromagnet alternately magnetised and demagnetised by the current that is controlled by the governor. The ratchet wheel advances one tooth at each contact, and so describes a complete revolution at the end of a certain number of contacts; and since the wheels in each meter have the same number of teeth they will all revolve at the same rate, which rate is controlled by the governor. Claims: (1) In a system of distribution of electric energy the employment of a series of meters, the registering apparatus of each of which is actuated by a uniformly intermittent and simultaneous movement regulated by a governing apparatus at any convenient point on the circuit and transmitted in a similar manner to that employed with electric clocks, whereby the quantity of electricity consumed at different points during equal periods of time may be registered; (2) the improvements in or appertaining to electric meters as described.—No. 2168. February 7th, 1889. 8*d.*

SWITCHES.—*H. Parker & E. S. G. Rees, Wolverhampton.*—In a switch constructed according to these improvements there are two diametrically opposite fixed contacts, between which there is a stud on which a cross-bar is pivoted so as to be capable, when turned in one direction, of disconnecting the fixed contacts, and thereby opening the circuit. An inclined plane is employed in combination with the cross-bar in order to compel the movement of the cross bar along the stud during a portion of its rotation. A spring preferably coiled around the stud is arranged so as to tend to force the cross-bar into the open position. In opening the circuit just as the ends of the cross-bar are about to leave the fixed contact bars or brushes, the spring and the inclined planes combine to force the ends of the bars suddenly out of contact, and thus make a quick break of the circuit. Claims: (1) An electric switch constructed and operated as described; (2) in an electric switch the combination and arrangement with two fixed contacts of a centrally pivoted cross-bar working during a part of its rotation on an inclined plane, a spring, and a handle or key for operating the same as described. No. 3907. March 6th, 1889. 6*d.*

ELECTROMAGNETIC DESPATCH APPARATUS.—*H. J. Haddon, London.* (*J. T. Williams, New York, U.S.A.*)—This apparatus is intended for the transportation of letters and packages. Fig. 1 shows a longitudinal section of the tube with a carrier, and Fig. 2 a transverse section of the same. In the tube or guide A there are two metallic rails B B¹. The rail B is continuous, but the rail B¹ is made in sections insulated from each other. At certain distances along the tube there are solenoids C C¹ C² C³. These solenoids are electrically connected to each of the different sections of the rail B¹, and also to a continuous conductor E. The conductor E and the rail B are connected up to the different poles of an electric generator D. The body of the carriage F is made of soft iron, and it travels upon wheels H H¹, I I¹, which run upon the rails B B¹. The wheels H I and H¹ I¹ can be electrically connected respectively by switches G and G¹. If it is required to send the carrier in the direction indicated by the arrow, the wheels H I are connected by the switch G, and so electric communication is formed between the poles of the

generator D and with the solenoid C in circuit. The solenoid C is thus vitalised, and draws the carrier along with it until it forms fresh connections with the succeeding solenoids. Claims: (1) The combination with the guide A, the continuous rail B and the sectional rail B¹ secured in said guide, the continuous conductor F and the solenoids C C¹ C² C³, mounted on said guide, of a wheel carriage F, the wheels of which engage the rails B B¹, and are in metallic contact with the same and with each other, and suitable connections between the solenoids, the conductor E, the rails B B¹, and a generator of electricity; (2) in an electromagnetic despatch apparatus or port electric a carriage F, provided at each end with a pair of wheels, which are insulated from each other, and a switch mechanism for bringing the wheels at each end in metallic connection.—No. 17765. November 7th, 1889. 6*d.*

CHEMISTRY.

FRACTIONAL DISTILLATION.—*B. Hoff, Galicia.*—The inventor describes a modification of the process of separating liquids of different boiling points by means of fractional distillation. The liquid is first vaporised, and the gases thus generated are passed through a series of chambers in which there is a condensing surface of silicious material, such as flint. The gases of the liquid with the highest boiling point are condensed in the first chamber, and those of the liquid with the lowest boiling point in the last chamber. The surface and capacity of each chamber are of course regulated according to the constituents of the mixed liquid under treatment. Claims: (1) The process whereby gas from several liquids of unequal boiling point is conducted through a vessel under one single distillation only, without using cooling water for condensing, the vessel containing silicic acid, &c., so that the gases of higher boiling point are condensed, whilst the gases of lower boiling point escape in the shape of steam, and are only ultimately condensed in the cooler as a pure product; (2) for apparatus described.—No. 3468. February 26th, 1889. 8*d.*

COLOURING MATTERS.—*T. R. Shillito, London.* (*J. R. Geigy & Co., Basel*).—This invention consists of the synthesis of tricarbo acids of aurine and its homologues by the oxidation of salicylic acid or β-cretosonic acid and one of the methane derivatives, such as methyl alcohol, methyl aldehyde, dioxydiphenylmethane dicarbo acid, &c. As an example of the process, two parts of salicylic acid are dissolved in fifteen parts of concentrated sulphuric acid and four parts of methyl alcohol. This solution is heated to about 70° C. and then 1½ parts of sodium nitrate are added. After a short time the solution becomes green, and it is then poured into water. The new product is precipitated. One claim is made.—No. 3333. February 25th, 1889. 4*d.*

Copies of the British specifications may be obtained on application to H. READER LACK, Esq., *Comptroller-General, Patent Office, Southampton Buildings, London, W.C. The published price must be remitted, together with a sum sufficient to cover postage, which may be reckoned at ½d. for every 10d. or fraction of 10d. Remittances exceeding one shilling must be made by Post Office Order.*

ON THE COMPOUNDING OF LOCOMOTIVES BURNING PETROLEUM REFUSE IN RUSSIA.*

In fulfilment of his promise made in a former discussion upon the Compounding of Locomotives (Proceedings 1886, page 391) the author has much pleasure in now communicating to the Institution the results of the experience he has thus far acquired in the compounding of existing petroleum-burning locomotives on the Grazi and Tsaritsin Railway in South East Russia.

Amongst the conflicting opinions entertained as to the utility of compounding in locomotives, the author, like many others, had his doubts on the subject in 1886. In order to satisfy himself on the question, he obtained the sanction of the Government for altering one locomotive by way of experiment according to his own plans. The altered goods engine No. 35 was put to work on 1st September, 1887; and after some modifications in the valve-gear, suggested by indicator diagrams taken in preliminary trials, it was finally completed, and the driver was allowed over a month's running to get fully acquainted with the handling in regular service. Comparative trials were then made of the compound against a non-compound with the same weight of train on the same days, the two trains being run one after the other with an hour's interval between, so as to expose them both to the same circumstances in regard to weather. It was proved without doubt that the compound burnt 22 per cent. less of the petroleum refuse used as fuel than the non-compound.

In consequence of this very favourable result the compounding of other locomotives was at once proceeded with. At the time of writing (December, 1889) there are already in daily use in the regular train service on this line twelve compound goods engines with six wheels coupled, and three compound passenger engines with four wheels coupled, all of which are doing very well indeed; and in the shops, in course of reconstruction, two passenger and four goods engines. It is intended to go on altering the rest of the locomotives to the compound plan as fast as the limited means in the railway works at Borisoglebsk will admit of this being done.

Economy of Compounding.—The fuel economy in the passenger engines the author believes cannot be less than 20 per cent. in the second or third notch, though there are not yet data enough for confirming this opinion with absolute certainty; it will be greater when the drivers manage the engines better. The mean economy in the twelve goods engines is now found to be 18½ per cent., which is a very good result, though less than what was got in the actual trial of the first one compounded. Including the three passenger engines therefore, the fuel economy in the compounded engines may now be safely taken at 18½ per cent. in comparison with ordinary locomotives. Last winter, 1888-89, was exceptionally severe, with from 55° to 65° Fahr. of frost; but the compounds ran equally well with the other engines, giving no inconvenience on account of the great cold.

Dimensions of Engines.—During the progress of these alterations, and of the author's observations on the working of the altered engines, several difficulties developed themselves, for which remedies had to be devised; those will no doubt interest all engineers concerned in the adoption of compound locomotives. In the accompanying illustrations, Figs. 1, 2, and 3, are shown a side elevation on the high pressure side, a transverse section through the smoke-box, and a sectional plan, of one of the altered six-wheel coupled 36-ton goods engines, of which the following are the main dimensions affecting the compounding:—Cylinders 18½in. and 25⅝in. diameter, and 24in. stroke; ratio of areas, 1·000 to 1·912. Slide-valves, maximum travel, 4¾in.; angle of advance of eccentrics, 20°; high-pressure valve, outside lap 0·81in., inside clearance 0·08in.; low-pressure valve, outside lap 0·67in., inside clearance *nil*. Stephenson link-motion. Receiver, capacity, 3·98 cubic feet; surface exposed to smoke-box heat, 11·52 square feet. Boiler pressure, 9 atm. = 135lb. per square inch above atmosphere. Six wheels, all coupled, 4ft. 3in. diameter. Adhesion weight, 36 tons. Tubes, number 151, outside diameter, 2⅛in.; length between tube-plates, 13ft. 10⅛in. Heating surface, tubes, 1164 square feet; fire box, 67 square feet; total, 1,231 square feet. Fire-grate area, 17 square feet, prior to burning petroleum; but no fire-grate is now used.

In Figs. 7 and 8, page 172, are shown sections of the two slide-valves. The diameter of the high-pressure cylinder is 18½in., and of the low-pressure 25⅝in., the piston areas being consequently 269 and 516 square inches, or in the ratio of about one to two. The original stroke of 24in. is retained unaltered, and the boiler pressure is 135lb. per square inch above the atmosphere. On first testing the engine with the original eccentrics, giving the valves a maximum travel of 4¾in., and having an angle of advance of 30°, it was found from the indicator diagrams that very excessive compression took place in the high-pressure cylinder, and too early a cut-off in both cylinders. The new eccentrics now used for all the compounded locomotives give the valves an increased travel of 4¾in., and have angles of advance of 20°. The indicator diagrams, Fig. 20, page 173, taken in forward gear since these alterations were made, show an improved distribution of steam, the engine giving out ample power in the third and fourth notches for the heaviest trains up the steepest gradients on the line, of 1 in 125; in fact, so far as the power of the engines is concerned, the compounds take their regular turns in the service, drawing the same number of trucks as the non-compounds, and keeping punctual time. The trial trains as well as the ordinary trains in summer consist of thirty loaded trucks of 16 tons each, or a total load of 480 tons exclusive of engine and tender. In these indicator diagrams 10 per cent. has been added to the mean pressure in each cylinder, in order to allow for the effect of the pipe connection from the cylinder to the indicator. All the engines have screw reversing-gear, enabling the driver to use any degree of expansion intermediate between the extreme limits of mid gear and full gear; and the four and five notches mentioned on the diagrams and in the appended Tables 1 to 8 are given merely for comparison with the ordinary nomenclature when a reversing lever and a sector with four and five notches are used. For the driver's guidance a corresponding notched indicator is added, which is shown double full size in Fig. 9 as fitted on the reversing gear for the passenger engines.

In Tables 5 and 6 are given the particulars of the working of the first compounded passenger engine No. 110; and in Fig. 19 are shown the corresponding indicator diagrams taken in forward gear, which are seen to be very good; the passenger engine indeed seems to work rather better than the goods.

Tractive Power.—An opinion prevails among engineers that the compounding of existing locomotives, when retaining the original boiler-pressure without augmentation and also retaining one of the original cylinders to form the high-pressure cylinder in the compound, must result in a considerable reduction in the tractive power of the compound as compared with the non-compound engine. In order to clear up this point, and ascertain fully what are the relative tractive powers of compound and non-compound locomotives, a series of comparative trials were made by the author during the summer of 1889 with both passenger and goods engines. A complete trial train of equal weight was made up for each passenger engine, the gross load being equal to its full adhesion; and similarly for each goods engine. Indicator diagrams were taken at each notch, at the slow speed of only ten miles an hour. At the same time a dynamometer was placed between the tender and the train, to show the actual tractive force exerted upon the train. The trials were all made up hill, from Borisoglebsk up to Gribanovka, a distance of eleven miles, with the maximum incline of 1 in 125 for the greater part of the way, and with frequent curves of 2,100ft. (32 chains) radius. In Fig. 18 is shown a profile of this portion of the line. The boiler pressure was the same in all cases, namely 9 atmospheres effective, or 135lb. per square inch above the atmosphere. The results are given in Table 7 and Figs. 19 and 22 for the passenger engines, compound and non-compound, both of which took trains of 344½ tons exclusive of engine; and in Table 8 and Figs. 20 and 23 for the goods engines, which took trains of 463 tons net.

In the compound passenger locomotive, as shown in Fig. 15, the tractive power undergoes the following diminution, as compared with the non-compound, in the five successive notches of the reversing lever from the earliest cut-off to full gear:—

1st notch	tractive power	42	per cent.	less in	compound.
2nd notch	,,	,,	28	,,	,,	,,
3rd notch	,,	,,	17	,,	,,	,,
4th notch	,,	,,	7	,,	,,	,,
5th notch (full gear)	,,	,,	5	,,	,,	,,

1	20	131	524	167	1·449	4·2 = 1 to 24
2	18	117	468	366	3·395	10·0 = 1 to 10
3	15	100	400	482	5·116	14·7 = 1 to 6·8
4	13	87	348	478	6·112	17·5 = 1 to 5·7

The high-pressure cylinder in this engine was worn out and had a crack in its body, and a liner was therefore put in, whereby the clear working diameter was reduced to 460 mm. = 18·11in.; whereas the first engine compounded, No. 35, with high-pressure crank leading, had its cylinder re-bored to 470mm. = 18·50in.

In the compound goods locomotive, as shown in Fig. 16, the diminution of tractive power as compared with the non-compound is as follows for the four notches:—

1st notch .....tractive power 27 per cent. less in compound.
2nd notch..... ,, ,, 17 ,, ,, ,,
3rd notch..... ,, ,, 10 ,, ,, ,,
4th notch (full gear) ,, ,, 5 ,, ,, ,,

Although the compounds thus show in full gear a diminution of 5 per cent., this difference from the non-compounds may for all practical purposes be neglected.

In Table 7 are given the indicated horse-power developed, and also the tractive force exerted by the passenger engines, compound and non-compound, each having an adhesion weight of 24 tons. At the third notch in the compound it will be seen there is a tractive force of 4·44 tons, equal to 18·5 per cent., or 1:5·4 of the adhesion weight, which is quite sufficient for all practical purposes. The maximum traction in the compound, at the fifth notch or full gear, reaches 5·17 tons, equal to 21·7 per cent., or 1:4·6, or more than one-fifth of the adhesion weight, which the author noticed was sufficient to slip the wheels on a perfectly dry rail. The increased tractive power shown in Table 7 over Table 6 is due both to the slower speed of only 10 miles an hour, and also to the cut-off being a little later, owing to wear of the valve-gear after longer running. The object of making these later trials in Tables 7 and 8 at the slower speed of 10 miles an hour, and at the full capacity of the locomotives, was to get fuller and clearer indicator diagrams than would be possible at higher speeds.

In the case of the goods locomotives, Table 8, having 36 tons adhesion weight, at the third notch in the compound a tractive power is attained of 5·56 tons, equal to 15·6 per cent., or 1:6·7; while at the fourth notch or full gear the maximum is reached of 6·42 tons, equal to 18·0 per cent., or 1:5·6 of the adhesion weight, which is quite sufficient for all practical purposes. Having fortunately been able to ascertain the foregoing facts from his own personal observations, the author will be very glad if they should be deemed sufficient to set at rest a question upon which a good deal of conjecture has hitherto existed.

In the calculation of the tractive power of the compound engines, the power of each cylinder is calculated separately by means of the formula:—Tractive power = 0·57 × boiler-pressure above atm. × (cyl. diam.)² × stroke ÷ (2 × diam. of driving wheels). The coefficient 57 per cent., which gives the mean effective pressure on the high-pressure piston in full gear, has to be replaced by a lower figure, deduced from indicator diagrams, when working more expansively; and for the low-pressure cylinder a still lower coefficient has of course to be taken.

Economy of Fuel and Repairs.—Table 11 shows the consumption of petroleum refuse, and the cost of engine and tender repairs, in six compound and six non-compound locomotives, one of each being a passenger engine and the other five goods; the results are those of five months' working in 1889, from April to August inclusive. The saving of fuel in the compounds is seen to have been 4·55lb. per mile, or 18·22 per cent. in the passenger engine, and a mean of 5·31lb. per mile, or 18·96 per cent., in the five goods engines, which together made 58,580 miles; in these five engines the saving ranged from a minimum of 14·75 to a maximum of 25·57 per cent. The saving in repairs was 49·2 per cent. in the passenger engine, and a mean of 28·8 per cent. in the goods. Naturally the whole of the saving in repairs must not be put down to the credit of the compounding alone, because all these compound engines had just passed through the shops and undergone a complete overhaul, so that they would reasonably require less repairs in running service than the old non-compound locomotives with which they are compared. None the less is the author of opinion, as the result of his own observations thus far, that the compounds will at all times require less repairs than the non-compounds, to the extent of probably at least 25 per cent., simply from the fact that the initial strains are not so high on the bearings and other mechanism in the compounds, and the force exerted by the pistons is continued upon the crank-pins for a greater distance during each stroke than in the non-compounds. Moreover, the friction of the slide-valves is much less in the compounds, because the back-pressure of about 60lb. per square inch under the high-pressure slide-valve tends to ease it off the face, while the low-pressure slide-valve is loaded to less than half the boiler pressure.

In Table 9, and graphically in Fig. 17, is shown the comparative consumption of petroleum refuse in compound and non-compound six-wheel coupled 36-ton goods engines doing equal work on the same section of line from 1st January to 31st October, 1889. During the first three months of severe winter the trains were much blocked by snow-drifts, causing the traffic to be very irregular; and as the compounds require just the same quantity of fuel as the non-compounds for keeping steam up while standing, they do not show so advantageously under such conditions as in long running service. The mean consumption per engine-mile for the ten months is seen to be 25·40lb. in the compounds and 30·65lb. in the non-compounds, showing a saving of 5·25lb. or 17·13 per cent. in the compounds. In conjunction with the mean saving of 18·96 per cent. shown in Table 11, the general average is roundly a saving of 18 per cent. for the whole of the ten months' working.

Slide-Valves.—The results of observation show that a very small difference in lap, outside or inside, amounts to a great deal in fuel consumption. The fuel sheets for all the compounds are every month carefully scrutinised, in order to see which particular engine burns least. Out of the twelve compound goods engines now running, No. 40, working between Tsaritsin and Archeda, has thus far proved the best from the commencement of its service in May, 1889, to the end of October; although over the shorter period covered by Table 11, No. 43, which began running in June, 1889, between Archeda and Filonoff, happens to show a little better. A longitudinal section of the two slide-valves of this engine No. 40 is shown in reduced size in Figs. 10 and 11; and particulars of their setting are given in Table 10. The full travel of the valves in each case is 4¾in., and the exact amounts of their lap are as follows:—High-pressure valve, outside lap 20mm. = 0·79in., inside clearance 1½mm. = 0·06in.; low-pressure valve, outside lap 15½mm. = 0·61in., inside lap 2mm. = 0·08in. A trial, however, is now being made of a low-pressure valve with an increased inside lap of 3mm. = 0·12in., with a view to increasing the compression in the low-pressure cylinder in order

Digitized by Google

to take up the extra momentum due to the greater weight of the larger piston; and this difference in the inside lap is now being watched over a lengthened period of working, for determining its importance in accomplishing the desired object.

Relieved Slide-Valves.—For relieving the pressure of the slide-valves on their faces the author has adopted the plan shown in Fig. 12 for the high-pressure valve, placing over the back of the valve a fixed table or back-plate B, against which bear a couple of relieving rings R, let into annular grooves in the back of the valve, and pressed outwards against the plate by the steam getting under them through a small hole H made for the purpose. Any steam leaking through past the rings escapes through the tube T open to the atmosphere, whereby the valve is relieved from the steam pressure over the area enclosed within the two rings R. For the low-pressure valve the arrangement shown full size in Fig. 13 is adopted, consisting of a piston P in a cylinder of 6in. diameter, exposed to the steam pressure underneath and open to the atmosphere above, thus tending to lift the valve off its face by means of the connecting link L. This latter plan was tried on eight engines and did very well, but has been temporarily abandoned because it made so much noise when running without steam. In other respects, however, the author is so satisfied of its value that he intends to try it once more, and see if the above objection cannot be obviated. It will be seen that in neither of these plans for relieving the slide-valves are any springs used.

Sequence of Cranks.—The first four compounded engines turned out of the shops had their high-pressure crank leading and low-pressure following in forward running; and in Tables 1 and 2 are given the corresponding mean steam-pressures, and temperatures of steam, and power developed. In order to test the effect of the reverse sequence of cranks, one goods engine, No. 53, was altered to have the low-pressure crank leading and the high-pressure crank following in forward running; and in Tables 3 and 4 are given the corresponding particulars for comparison with Tables 1 and 2. From the indicator diagrams taken in forward gear with the latter arrangement, shown in Fig. 21, it will be noticed that inconvenient and very excessive compression takes place at the first notch in the high-pressure cylinder, so much so indeed that this notch is not used; but in all the other notches a good distribution takes place. In the low-pressure cylinder a much better distribution takes place at all notches compared with engines having the high-pressure crank leading; and this engine with the low-pressure crank leading, which has only recently been put to work, seems to develop more power and to burn less fuel than the others having the high-pressure crank leading. This is the first time, so far as the author is aware, that the sequence of cranks in compound locomotives has been taken into consideration. The receiver capacity is equal to that of the high-pressure cylinder; and all the dimensions are the same in both the above cases. Four goods engines now have the low-pressure crank leading, while all the passenger have the high-pressure leading.

The idea of making one engine by way of trial with the low-pressure crank leading in forward running originated in its being accidentally noticed that one of the other engines, compounded with the high-pressure crank leading in forward running, seemed to work better and to be more powerful, developing its full tractive force with an earlier cut-off and making steam with greater freedom, when running backwards with its train, in which case of course the low-pressure crank became the leading one. The line following generally the undulating contour of the plains, its profile has very long gradients of 1 in 125, thus demanding for long stretches at a time the full power of the engine, or say about the third notch out of four. The only objection the author now sees to the low-pressure crank leading is that it gives too much power in the large cylinder and too little in the small, thus putting the engine out of equilibrium; but this irregularity will in a great measure be obviated by having a receiver about half as large again as those now used on all the present compounds.

Air-inlet Valve.—When the first passenger compound was put into regular train service, it was noticed that, where an ordinary non-compound ran easily down hill with the regulator closed, the compound ran very stiff, and even required the regulator opening a little: thus proving that an increased internal resistance existed in the compound locomotive, which was traced to the large area of the low-pressure piston creating a strong vacuum in the receiver. This was overcome by placing on the receiver an air-inlet valve opening inwards, Fig. 14, for enabling the large piston to draw in air when required, as is invariably the case when the steam is shut off. Since the addition of this valve the engine runs down hill with even greater ease than a non-compound locomotive. As for the objection that such a valve cools the low-pressure cylinder, the author had to choose one of two inconveniences: either to keep steam on when running down hill, or to cool the cylinder. The latter proves the more profitable method, and is accordingly adopted.

Subsequently the author has arranged for mixing part of the hot smoke-box gases with the cold air, and admitting this mixture into the low-pressure cylinder at a temperature of from 120° to 180° Fahr.: this can easily be done without risk of injury to the valve-faces and piston-rings, because no solid particles from cinders or ashes exist in the smoke-box of these engines burning petroleum refuse. The plan adopted is shown in Fig. 6, and consists in placing upon the receiver R a short perforated pipe P of 2⅛in. bore, projecting into the smoke-box, the aggregate area of the perforations being double the area of the pipe. In order that the hot gases alone may not get into the cylinder and cause damage by their great heat, a couple of air holes are made in the flap-valve F which closes the top of the stand-pipe above the high-pressure valve-chest; the joint area of the two holes is about one-quarter that of the gas pipe P, so that the air and gas get mixed in the proportion of about one to four, which, as far as the author's experience goes, is quite sufficient for preventing over-heating. The results are very good; the cylinders no longer get cooled as they did before, and when the regulator is opened afresh less steam is condensed, or possibly none at all. The flap-valve F is closed by a light spring, and is at once blown wide open whenever the engine is made to work non-compound at starting.

Starting Valve.—The starting valve on the receiver, for admitting boiler steam direct to the low-pressure cylinder for starting, is worked by hand by the driver, and is not automatic in closing, its only merit being that it is exceedingly simple. In fact, these valves were already in stock, having formerly been used for steam-brakes on the locomotives. It cannot therefore be pretended that they present the same excellent features as the special automatic starting valves which have been introduced elsewhere and and have proved so efficient in working. In the author's locomotives retaining their original boilers it must be borne in mind that his whole attention was directed simply to obtaining from old engines compounded with 8½ to 9 atmospheres pressure the nearest and cheapest approach to modern compounds having 12 atmospheres pressure. As to any possibility of a wasteful expenditure of steam through abuse of the starting valve, this is sufficiently guarded against by the drivers being paid a premium for saving fuel; they are, as a rule, fully alive to their own interests, and never use the starting valve more than is absolutely necessary. In Figs. 5, 4, and 6 are shown a side elevation on the high-pressure side, a plan, and a transverse section through the smoke-box and cylinders, of a compounded passenger engine having a hand interchanging valve, in addition to the hand intercepting valve; the two together enable the engine to continue working non-compound for any length of time, instead of for only the first stroke at starting; and the interchanging valve, when the intercepting valve is either open or closed, serves also as an air-inlet valve for both cylinders in running down hill with the steam shut off. In Fig. 14 is shown the arrangement of these valves, which are indispensable for starting heavy trains without jerks.

Receiver.—The first compounded passenger locomotive had a receiver capacity equal to the volume of one stroke of the high-pressure piston; but in two recently compounded the receiver has been enlarged to 1·3 times that capacity, by the addition of

The boiler pressure in all these engines, both Compound and Non-compound, was 135lb. per square inch above the atmosphere.

The Trucks were each about 16 tons gross load.

In the three columns of Economy, the five Compound and five Non-compound goods engines are compared severally, according to their order of sequence:—Compound No. 35 with Non-compound No. 48, and so on to Compound No. 58 with Non-compound No. 63. The mean results show the comparison between the two groups collectively.

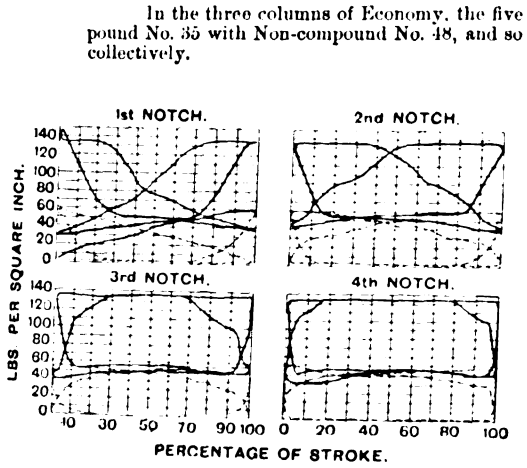

FIG. 19.

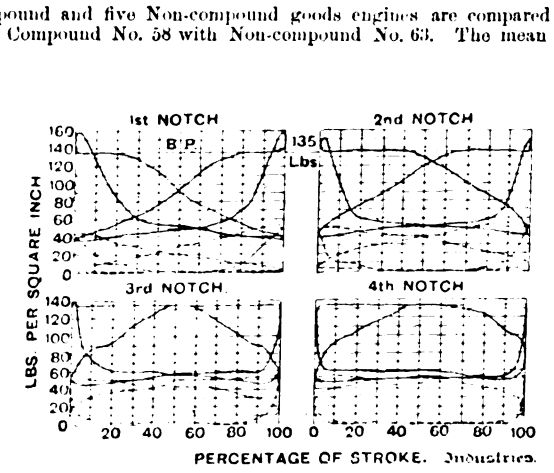

FIG. 20.

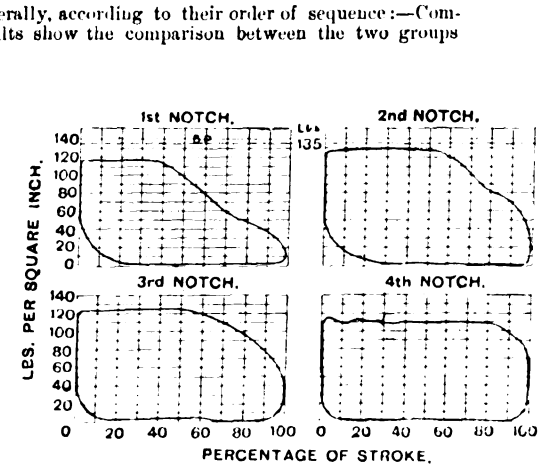

FIG. 22.

the pipe A in the smoke-box, as shown in Fig. 6. Both these engines have the high-pressure crank leading in forward running. The enlargement of the receiver is a step in the right direction, by more nearly equalising the power in the cylinders. There is less back-pressure in the high-pressure cylinder, and a greater quantity of steam in the receiver for charging the low-pressure cylinder; and although this steam is of slightly lower pressure, yet the diagrams from the low-pressure cylinder come out fuller. In other words, before the receiver capacity was increased it was found that the pressure in the low-pressure cylinder dropped at once on the piston starting at the beginning of its stroke; but with the enlarged receiver the pressure does not drop so fast.

In the compounded goods locomotive No. 28, recently put into service, with the low-pressure crank leading in forward running, the receiver has been further enlarged to 1·8 times the capacity of the high-pressure cylinder. The result is that not only is the pressure well kept up in the low-pressure cylinder from the beginning of the stroke, but also the influx of steam from the high-pressure cylinder takes place before the admission to the low-pressure cylinder is cut off at some notches of the valve-gear. Thus a pretty even pressure is obtained in the large cylinder, giving a good diagram for this cylinder, while at the same time, owing to the sequence of cranks, less resistance is offered to the exit of the steam from the high-pressure cylinder, except at the first notch or greatest expansion. From three months' performance, during September, October, and November, 1889, engine No. 28 seems to work very well; and for this result three reasons may be assigned. Firstly, the hangers to the link-motion are made ¼in. longer on the low-pressure side than on the high-pressure, causing a later cut off in the low-pressure cylinder than in the high-pressure. Secondly, the blast pipe is set 12in. lower down in the smoke box than in the other engines, keeping its nozzle at about the height usual in English engines, say about 8in. above the top row of tubes. Thirdly, the receiver as already stated is made 1·8 times the capacity of the small cylinder. Any one of these three points may have a useful effect upon the better

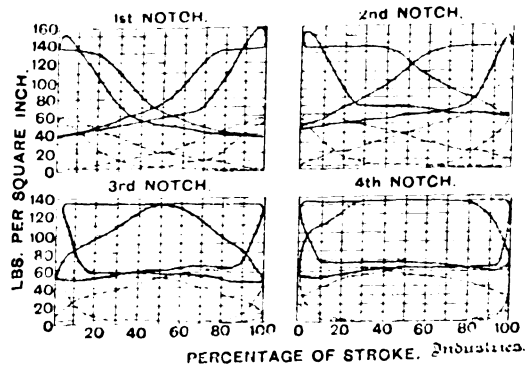

FIG. 21.

working of the engine; and the combination of all three together has undoubtedly the effect of saving a trifle more fuel; but to which of the three it would be right to assign the benefit it is impossible at present to say.

The results of the author's experience are such as to leave no doubt in his own mind that compound locomotives are the engines of the future in all countries. Plans are already in hand for compounding the eight wheel coupled 48-ton goods locomotives; and advantage will be taken of the alteration of these and other engines to substitute also the relieved slide-valves above described, so as to save the extra 5 or 6 horse-power at present absorbed by the friction of the slide-valves. The Government railway authorities have decided in future to order all new locomotives on the compound principle.

FOREIGN INDUSTRIES.

(From our own Correspondents.)

(FOR LATEST TELEGRAPHIC DESPATCHES SEE PAGE 177.)

PARIS, 18th February, 1890.

IRON.—In their general aspect, the iron markets, as well of the capital as of the provinces, remain unchanged. Here in Paris the demand is slack, but prices are firm, at from £8 8s. to £8 15s. for bars and joists. Old rails are scarce at £4 12s. In the Haute-Marne the makers of wire cannot meet the demand, which is now exceptionally strong. The retrograde movement in the English markets, and the consequent retardation of business in those of Belgium, have somewhat shaken the confidence of buyers and checked a further rise. It is a commonly held opinion that prices have touched their highest point. The export trade seems to be steadily growing.

COAL PRODUCTION.—The *Journal Officiel* publishes the statistics of coal production in France in the year 1889 The total output was 24,588,880 tons, an increase of nearly two million tons relatively to 1888. The increase would have been fully half a million tons greater had not the strike occurred in the basin of the Pas-de-Calais. The production of the latter district amounted to 8,646,919 tons, and that of the Nord to 4,809,065 tons. Relatively to last year this is an increase of 9 per cent. for the former and 10 per cent. for the latter.

BERLIN, 17th February, 1890.

COAL AND COKE.—The falling off in the demand for house coal has relieved the tension which kept the Upper Silesian markets in an extremely sensitive state. The railways are now able to cope with the traffic, and deliveries are consequently made more promptly. This altered situation is, of course, favourable to the iron and steel industry, the production of which has been restricted of late by the want of fuel. Several of the new coke ovens constructed to save the tar and ammonia products will be ready for work in a few weeks. At the Falvahütte works several ovens on the Collins system are in course of construction. The imports of coal and coke into Germany in the year 1890 were as follows: Lignite (from Austria-Hungary), 5,650,966 tons; coke, 387,395 tons (from Belgium, 287,466 tons); coal, 4,573,209 tons (from England, 3,400,450 tons); briquettes, 51,769 tons (from Belgium, 35,201 tons). The exports were: Of lignite, 14,270 tons; of coke, 814,613 tons; of coal, 8,860,217 tons; and of briquettes, 93,385 tons. Of the coal exported, 3,128,079 tons were sent into Holland and 3,098,302 tons into Austria-Hungary. French and Austrian consumers purchased most of the coke exported.

IRON.—Though the current of trade has slackened considerably in the Rhenish-Westphalian markets, there is no retardation observable in those of Upper Silesia. The opinion, however, commonly held is that prices have touched their highest point. The Upper Silesian convention of rolled iron manufacturers has been prolonged for three years. In the Berlin market business is active, the demand for joists increasing as the spring approaches. The lowest tenders for the 6,300 tons of steel rails for the Berlin railway were received from the Gütehoffnungshütte at Oberhausen, and the Hösch Iron and Steel Works at Dortmund, whose prices were 165s. and 165s. 6d. respectively.

GERMAN IRON ABROAD.—The German export iron trade has suffered considerably from the effects of the high prices brought about by the syndicates of manufacturers in 1889. It is not possible, by reason of the changes made in the Customs Union, to compare the exports of last year with those of 1888; but it is certain that a serious shrinkage has taken place in the total trade. The exports in December amounted to 70,846 tons, exclusive of machinery, steam boilers, and ordnance, against 81,353 tons in November. The following is a classified account of the exports in the last month of the year and in the twelve months of 1889. Pig iron, 9,280 (156,434) tons; old iron and scrap, 1,740 (33,284) tons; half wrought iron and steel, 1,653 (20,847) tons; finished iron and steel (bars, angles, and plates), 18,042 (280,254) tons; wire, 10,386 (156,582) tons; wire nails, 3,686 (46,411) tons; rails, 9,386 (110,979) tons; other railway iron, 4,051 (52,185) tons; heavy castings, except ordnance, 1,793 (19,334) tons; other manufactured goods, except machinery, 10,829 (121,317) tons. Total, 70,846 (997,325) tons. The exports of wire to Great Britain in December amounted to 2,291 tons, making 33,575 tons for the year. The shipments of wire nails to Great Britain in the same periods amounted to 1,097 tons and 12,615 tons respectively. In the course of the year 10,338 tons of wire nails were shipped to Japan.

NEW RANGE-FINDER.—In military circles a new range-finder is spoken of as superior to anything of the kind previously in existence. Up to 7,000 yards it indicates distances with a degree of accuracy hitherto unapproached. The instrument, the readings of which are determined by geometrical methods, is the invention of Captain Erle, a staff officer of the German artillery.

SHIPBUILDING IN GERMANY.—The scheme which was under consideration by the Vulcan Shipbuilding Company, for the erection of a shipbuilding and repairing yard at Bremerhaven, has been abandoned on account of want of capital. A new shipyard is to be built on the Vistula. Owing to the site of the yard being very low, it is proposed to transport soil and earth to raise its level. A wire-rope railway will be employed to bring the earth from a neighbouring hill some hundreds of yards away.

VIENNA, 17th February, 1890.

THE COAL MARKET.—There is great activity in the Bohemian coal market. During the last few weeks the export to Bavaria has begun to revive. This export was at its maximum in 1888, when 572,929 tons were sent there. Ten per cent. of this quantity were consumed at Munich alone, whilst 40,000 tons went to Nuremberg. The greatest part of the export went to the Bavarian State railways for their own consumption. The Nordböhmische Kohlenwerks-Gesellschaft placed its shares last week on the Vienna Bourse, and they had a good sale. At the works of this company 1,400 hands are employed, and the daily production amounts to 2,700 tons; in January the works produced the total quantity of 70,350 tons, being nearly double the production of the same time in 1889. Last year's profit was 155,000fl. During the last twenty years the production has increased sixfold—viz., 1·6 millions to 9·2 millions. During the last year the greatest increase was at the Brux works, which in 1870 produced only 0·7 per cent. of the total quantity, whilst now it produces 27 per cent. of the coal quarried. The good quality of the coals and the excellent communication with the railways have caused this important increase.

THE IRON MARKET.—The animated traffic is being followed daily by increasing prices. In pig iron the demand is very much greater than the supply. Last week the Bohemian Ironworks raised the price of rolled steel plates by 10fl. per ton, and the Hungarian syndicate of rolling mills declared an increase of 5fl. per ton in the price of sheets. There is great activity in machine construction and in locomotive and waggon building. The Aussig-Teplitz railway has ordered 200 coal waggons with a capacity of 15,000kg.

ELECTRICAL ENGINEERING. Two more towns in Austria have decided on adopting the electric light for the purposes of illumination. At Carlsbad the town authorities have determined to spend 350,000 florins in the construction of a central station. At Brünn the matter is not as yet settled. The electric lighting installation at Cologne is to be supplied with long-distance cables on the Zipernowski-Deri-Blathy system, and with apparatus made by Messrs. Ganz, of Budapest.

BRUSSELS, 18th February, 1890.

THE COAL MARKET.—The tendency of the market towards a normal state of affairs continues at work, and at most of the collieries the stocks are being replenished. In the following table the imports and exports during the years 1888 and 1889 are compared with one another:—

Imports.

	1888.		1889.
Coal.....	1,033,169 tons	.....	1,002,194 tons.
Coke	27,461 „	.....	18,259 „
Briquettes ...	— „	.....	— „

Exports.

	1888.		1889.
Coal.....	4.141,908 tons	.....	4,257,694 tons.
Coke	1,060,754 „	.....	1,220.325 „
Briquettes ...	324,893 „	.....	316,439 „

The exports of coal have increased in all directions, with the exception of France, and the exports of coke have increased all round. During the week ending the 9th inst., 22,579 waggon loads of coal and coke were carried over the railways, as compared with 20,068 during the corresponding week of the previous year.

THE IRON MARKET.—The orders and demands are not quite so pressing in the iron market as they were a few days ago, but the current of business remains satisfactory, and there is no weakening in the scale of prices. The production of pig iron during the month of January amounted to 82,305 tons, as compared with 75,640 tons during the same month in 1889. The increase is entirely due to the improvement in the production of pig for making steel. The exports show that there is considerable progress in the iron and steel industries, and they have now risen to an unprecedented height. The exports of rolled iron have risen from 309,698 tons in 1888 to 332,987 tons in 1889, and of rolled steel from 87,936 tons in 1888 to 104,639 in 1889. The Couillet and Acoz Companies have obtained the order for 40,000 steel sleepers for the Congo Railway at the rate of 23·70fr. per 100 kilog.

THE GLASS TRADE.—At a meeting of the Glass Association on the 3rd inst. the formation of the syndicate for controlling the export of window glass to the United States was fully discussed, and a scheme drawn up for its establishment. A committee has been appointed to complete and extend the scheme and to draw up the statutes of the syndicate.

DÜSSELDORF, 18th February, 1890.

COAL.—The tone of business in the coal market is one of indecision. The prospect of a great strike of colliers in the North of England offers a set-off to the threatened general strike here in March, and tends to keep the market steady. The demand for house coal is rapidly falling off The merchants engaged in the export trade with Holland and Belgium resolved at the meeting held on the 13th inst. to make no alteration in prices. The consignments of Westphalian coal to Hamburg and its neighbourhood in the month of January amounted to 58,790 tons, against 61,350 tons in the same month of last year. The Hamburg trade proper shows an increase; the shrinkage is in the Altona to Kiel district. Relatively to January of last year, the price of coal delivered at Hamburg has risen 110 per cent., and that of coke 250 per cent. The tendency of the market is still upward for both Westphalian and English coal.

IRON.—The slower current of business in the iron market is not to be regarded as the beginning of a relapse, or as likely to be followed in any degree by weaker prices. The present level must be maintained so long as the raw materials of manufacture remain at the prices at which they are now quoted. As for coal, the tendency is toward higher rather than lower rates. Prices of pig iron remain steady. The market for finished iron and steel continues active, the demand being strong for bars, joists, and hoops. Makers of sheets have plenty of work in hand, sufficient for several months to come. At a meeting of the West Germany Sheet Makers' Syndicate, held at Siegen on the 12th inst., the convention was prolonged. Three hitherto outstanding firms joined the syndicate. The official list of prices made up for the 15th inst. is as follows:—Good merchant bars, 210s.; angles, 215s.; joists, 150s.; hoops, 215s.; ingot iron and Bessemer steel bars, 205s. to 210s.; boiler plates, 260s. to 265s.; common plate, 235s.; sheets, 255s.; rolled iron wire (nail quality), 195s.; wire nails, 220s.; rivets for boilers, bridge work, and ships' plates, 290s. a ton at works.

BELGIAN COMPETITION.—The industrial world of this region is much disturbed by the results of recent tenderings for railway rolling stock for the German State railways. The stock consisted of 3,170 goods waggons, to be delivered in a short space of time. The tenders of Belgian manufacturers were much below those of the German makers. For example, for 250 coal trucks provided with brakes, the lowest German offer was 2,430 marks per truck, while that of the Belgians was 2,280 marks, a difference of 150 marks. For 750 similar trucks without brakes, the lowest German tender was 1,840 marks per truck, a sum that was underbid by the Belgians in a like proportion. It will be seen that when the import duty is taken into account, the difference of price is large. Moreover, the Belgians offered to deliver in much less time than the Germans. As a consequence, important orders have been lost to German industry. But besides the present loss, a danger has been revealed which has given rise to grave anxiety.

LILLE, 18th February, 1890.

TEXTILE MANUFACTURES.—Business continues brisk in the market for linen goods. The turnover for the last week at Armentières was large, considerably above the average for this season, and the tendency is towards greater activity. The stocks in hand are about equal to those of last year. Provincial buyers are operating more largely. The Roubaix woollen goods trade presents no new features. The terminal wool market is reviving; the cause, however, must be sought among speculative dealings, for manufacturers are buying but sparingly. The reason alleged is that the February deliveries are defective in quality. Jute goods are in brisk demand.

FLAX AND YARNS.—Business in the flax market is scarcely so brisk as it was, and prices for home-grown produce have turned slightly in favour of buyers. A good deal of Russian flax has changed hands during the last week. There is a steady though not strong current of business in tows, the commoner sorts being offered plentifully. Buyers of yarns continue to restrict their dealings to what is strictly necessary. Prices are unchanged. Activity is still the characteristic feature of the jute market.

IRON.—The supply of coal having increased, the production of iron now proceeds without interruption. The market is very firm. For early delivery, bars and joists are sold at 160s. a ton; but for delivery later than March 31st, as much as 168s. has to be paid. This firmness is, however, due less to the activity of the market than to the high and still increasing cost of coal. Though our manufacturers are well provided with orders, they continue to push the foreign trade, and with considerable success, for export orders are coming in freely. There is a project under consideration for forming an export syndicate such as now exists for Algeria.

AMSTERDAM, 17th February, 1890.

ACCIDENTS IN FACTORIES.—The Government and a large number of factory owners have promised to exhibit in the coming Exhibition of appliances to minimise dangers to lives and limbs in factories, to be opened in Amsterdam in May. Many foreign companies and manufacturers have also announced their intention of exhibiting, and altogether this international show assumes much more important dimensions than was at first contemplated. The original guarantee fund is now considered inadequate. The committee asks for subscriptions to raise it by £1,000.

NEW LAND COMPANY AT AMSTERDAM.—The King has sanctioned the articles of association of the Transvaal Land Company, formed for the acquisition of lands in South Africa, particularly mineral lands in the Transvaal.

Digitized by Google

The capital is 720,000 guilders (say £60,000). The company will also foster emigration of Hollanders to the South African Republic, for which same purpose the Dutch South African Association is now endeavouring to create an emigration fund, by whose means loans could be granted to intending emigrants, sufficient to defray their outfit and passage out, also their first expenses on arrival, and repayable out of the subsequent earnings. In a pamphlet, recently issued at Amsterdam by the secretary of the association, it is pointed out that, with the increased emigration of Englishmen and Germans to the Transvaal, it becomes necessary to strengthen the Dutch element there by a constant infusion of sturdy peasants and artisans from the Low Countries. The systematic exodus of Dutchmen to North America, Canada, and the Argentine Republic is deplored, because they become lost to the fatherland in course of time, whilst in South Africa they would contribute to maintain the old stock. The Transvaal Government should encourage immigration like the Argentine Republic, but, failing this support, the next best thing to do is to start an emigration fund. The secretary of the Dutch South African Association cannot contemplate any difficulty in the matter, for wages are high in the Transvaal, and, consequently, it would be easy for the emigrants to repay the grants made to them.

The Workmen's League.—The Workmen's League of Holland will hold its annual meeting in April at Amsterdam. Apart from several political questions various matters that interest the workmen will be brought forward for discussion. Among these are sanitary dwellings and their control by the State; the creation of strike funds for the support of workmen and their families whilst strikes or lock-outs are going on; the various methods by which slackness or absence of work can be remedied; an energetic support of the proposed labour inquiry by a Royal Commission, so as to make it as stringent as possible; the legislative settlement of employers' liability in cases of the incapacitating of workmen through accidents in factories, &c.

New Steam Ironclad Corvette for India.—The Royal Engineering Factory at Amsterdam is now building the steam ironclad corvette "Sumatra" for Government service in the Dutch East Indies. The vessel is to have electric light and fish torpedoes attached.

A Gigantic Scheme.—It is proposed to build a dam or embankment in the Y before Amsterdam, so as to form a means of communication with the other side, instead of a bridge. This embankment would have openings, with drawbridges, to let through ocean steamers and other passing vessels as required. The cost is estimated at more than £200,000; on the other hand, it is estimated that the municipal lands at the other side of the Y, opposite Amsterdam, would enormously increase in value for building purposes by this scheme, and a profit of no less than ten million guilders (say, £800,000) is anticipated after its completion.

English Coals in Holland.—With the exception of a few collieries in Limburg, Holland has no coal mines of her own. Her annual consumption is about 4,500,000 tons, and nearly the whole of this large total has to be imported from abroad. Prussia supplies by far the largest part thereof. In 1889 she exported into Holland 3,587,502 tons of coal, against Belgium 400,479 tons, and England 501,314 tons, but, whereas the imports from Belgium only increased 10,600 tons, those from Prussia fell off 388,202 tons, whilst the English imports of coal advanced by 210,314 tons, which shows a great increase on the total import in 1888, only 291,000 tons. The increased arrivals from England in 1889 were due to the strikes in Germany, and it is probable that the English imports into Holland during 1890 will again show a material advance upon 1889, as many Dutch manufacturers, foreseeing a rise in prices, have contracted forward deliveries in England, which have yet to arrive. These contracts are mostly at quotations much below the current ones, and so the Dutch consumers have been benefited; but, otherwise, the great rise in the coal prices has occasioned in Holland both inconvenience and losses. In many towns, the charge for gas has had to be raised. Thus in Utrecht, where the municipality has just contracted for the delivery of 40,000,000 hectolitres of coal at a minimum price of 94c., say 1s. 7d., the hectolitre, whilst the average price for the years 1885-1888 was only about 11d. per hectolitre.

COPENHAGEN, 15th February, 1890.

The Norwegian State Railways.—The total number of carriages on the Norwegian State railways is 3,627. Of these 3,032 are goods carriages, 419 are passenger carriages, and 176 are of various kinds. Some very large third-class carriages have just been received from the Kockum Engineering Works at Malmo, Sweden; they have a breadth of 2·9 metres, and length of 17·4 metres; they contain nine compartments each, with passage through, and one lavatory.

Wood Pulp Manufacture in Scandinavia.—The erection of new wood pulp manufactories continues, although the prospects cannot said to be particularly bright. Last year's production in Norway was a very large one, and this year's will of course be still larger. There will shortly be fifty-four wood pulp manufactories in work in Norway, against the fifty working last year, and their probable production has been put at about 250,000 tons. The export during last year was about 190,000 tons, which is again some 15,000 tons in excess of the production during the previous year. These figures refer to mechanically made wood pulp of chemical wood pulp the export has amounted to about 25,000 tons, of which rather more than half was wet wood pulp. This, too, is considerably above the export of this kind of wood pulp during 1888. Of manufactories for chemical wood pulp there were fifteen going at the end of 1889, eleven sulphite and four soda cellulose works. Their production is estimated at 30,000 tons sulphite (wet), and 9,000 tons soda cellulose (dry). The chemical wood pulp has not experienced such an unfavourable market during last year as has the mechanical, the former having maintained its price and commanded a satisfactory and ready sale. The value of the exported chemical wood pulp during 1889 has been put at approximately £200,000 f.o.b. Norwegian port. From a financial point of view the result has hardly been so satisfactory as one might expect, owing to the important rise in nearly all the requisite raw materials. For mechanical wood pulp, matters are, however, far more unsatisfactory, and prices, which have been gradually declining for the last twenty years, reached during the past year the unprecedented low figures of £2 2s. 6d. f.o.b. Hull. Attempts have been made to reduce and regulate the production during the present year of wood pulp in Scandinavia, as of iron in Sweden, but while Scandinavian farmers seem to have a happy knack of co-operating to mutual advantage this cannot be said to apply to the manufacturers, and however beneficial to all concerned an arrangement of this nature might prove, it is not very likely to come to anything. The value of the Norwegian export of mechanical wood pulp during 1889 has probably amounted to about £450,000. As is natural, the increasing production of wood pulp has given an impetus to the Scandinavian paper industry. In Sweden, as has already been mentioned in this paper, two or three large paper manufacturing companies have been formed of late, and in Norway some of those already in existence have been materially extended. The effect of these extensions will, no doubt, be apparent before long.

Land Reclamation in Denmark. Few kinds of large undertakings have perhaps, as a class, proved more risky than those based upon the laying dry or reclaiming of land, but nothing in this line has probably more utterly failed than the attempts of the Danish Land Company, afterwards the Nissum Fjord Company, in Denmark. Not only have these companies expended very large sums without any results, but the Danish Government has now undertaken to restore the whole thing to its *status quo*, the deposit of the English company being used for the necessary works. The Nissum Fjord has an area of some seven square miles, and was separated from the North Sea by a narrow ridge of cliffs: the depth of water is only small, although, of course, variable, and with a constant easterly wind portions are virtually laid dry. The concession passed into the first English company through one or two intermediate parties, and the work was at once commenced with energy; the weak ridge of cliffs was strengthened by dams and a sluice was erected at the entrance to the fjord. The building of a strong dam was commenced so as to isolate the northern and eastern portion of the bay, but the subsequent history of the undertaking became almost an uninterrupted chapter of accidents. The sea made its way hrough at various times, the large sluice was damaged before its completion, and the leading engineer, Mr. Earle, lost his life in a gallant attempt to save some countrymen from an English vessel stranded on the coast. The thing was, however, persevered with, and in 1870 a Danish engineer succeeded in completing a sluice, which transformed the Nissum Fjord to a sluice. In 1871 a corner with an area of some 5,000 acres was isolated by a dam, about two miles long, varying in height from 6ft. to 10ft. above daily water level, and covered for a distance of 6,000ft. with a shell of concrete up to 4ft. height. Heavy steam engines and pumping machinery were fixed, including a centrifugal pump of 6,000 barrels capacity per hour. The water would, however, not disappear. The concession expired in 1880, but was prolonged for a few years. The work was continued, absorbing a lot of money, but, finally, the whole thing collapsed in 1885, and, the concession expiring, the Danish Government became again proprietor of the Nissum Fjord, as it had been up to 1864. The machinery, &c., were sold for a song, and the dam, just referred to, for £50. A whole colony of labourers were thrown upon their own resources, and negotiations have been pending with the Government as to having the Nissum Fjord again transformed to what it was before the works began, on account of its fishing and marsh land. This will now be done, the deposit of the English company being used for the purpose—rather a melancholy winding up, after all.

MADRID, 17th February, 1890.

Madrid Gas Works.—Notwithstanding the tremendous price of 9s. per 1,000ft. being rigorously kept up, the increased sale has continued unchecked so far. As it is, the company have not had to supply gas to the theatres, otherwise they could not have met the demand. The electric light is now obligatory in the theatres. Should the further introduction of electric light not affect their present sale, it is supposed that they will be obliged to erect new works on some other site. It is the high price of coke that makes their business so good and safe. They derive very little advantage from their tar, and for the ammonia there seems to be no demand, notwithstanding that at the port of Valencia sulphate is imported to a large extent.

Silver Coining.—The Government of Spain has bought 30,000 kilogrammes of silver bar to turn into coins. The sellers have been the Marquis of Villamejor and the representatives of Rothschild's house. There is no real want of silver coins for circulation, and the idea of the Government in increasing the quantity is to gain a profit.

The Robla and Valmaseda Railway.—The Bill for this special coal-carrying line has passed in the Lower House, and has been sent to the Senate, where it is sure to pass shortly. Commercially this line of 220 kilometres, or 140 miles, is one of the most promising in the market.

Cost of Coals in Asturias.—As Spain is preparing to use native coals more freely than in past time, serious attention is now being given to all questions connected with the cost of obtaining and carrying fuel. Lately an engineer who is a good authority in the matter has given the cost on an average of the coals in the Mieres and Langreo districts at 8s. per ton, interest and depreciation of plant included, at pit's mouth. The northern coals though very good for some purposes, are not so well suited for steamers as those in the south, which, however, are much dearer to work.

NEW YORK, 8th February, 1890.

The Iron and Steel Markets.—The market is in a fairly satisfactory condition, although in such shape as to warrant much enthusiam. Prices of pig iron have been quite irregular, No. 1 foundry selling from $19·50 to $20·50 per ton, No. 2 at from $18·75 to $19·25, and grey forge at $17·50 to $18·00. The leading companies are all sold ahead, and all that is in the market is the product of small furnaces. There is a good deal of this iron offering, however, and during the week buyers have not found it difficult to obtain small lots at very low figures. In manufactured iron the market has not been very active, but prices are steady, and holders do not show much disposition to make concessions. Mills are generally well employed on old contracts, and new business is not as abundant as could be desired. In a few instances a slight shading has been done on plates and bars, but, as a rule, 1·59c. to 2c. per lb. for bars, and 2·35c. for plates and angles, have been the ruling quotations. Steel rails are steady at $35·50 to $36 at mill, but only small lots are taken at these figures. Prospects are said to be very encouraging, and a heavy demand is looked for in the near future. Billets are in a fair demand at about $38·50 per ton, with a restricted supply.

The Metal Markets.—The copper market is quiet, with little business doing. Prices are 14¼c. for Lake and 13c. to 13½c. per lb. for casting brands. The tin market is more active, a fair amount of business being done at improving prices. Straits, spot, is quoted at 20·90c. to 21·35c. per lb. Plates are in moderate demand, and prices are low. Lead is dull; few sales have been made, mostly at 3·82½ spot. There is nothing doing in spelter. Antimony is in active demand at $40 for Hallet's and $31 for Cookson's.

New Locomotive Shops.—The new locomotive shops which the Pennsylvania Railroad Company has been building, about one mile east of Altoona, are completed as far as the buildings are concerned. There is still about $500,000 worth of machinery to be put in. When in working order they will be capable of turning out 150 locomotives per year, and will employ 1,000 men. The old shops at Altoona will be used only for repairing purposes.

Material for Cruiser Machinery.—Contracts have been awarded for material for building the machinery of cruisers 7 and 8, to be built by the Government at New York and Norfolk, as follows: Wrought iron bolts, 7,500lb., to J. B. Morsell & Co., of New York, $561 75; pig iron, 100 tons, to D. S. Cook, of Wrightsville, Pa., $2,050; 200 tons steel plates for boiler shells, to the Linden Steel Company, of Pittsburgh, $30,912; and 40 tons steel rods, shapes, and forgings for boiler bracing, $11,332, 22,500lb. wrought iron nut blocks, $2,250, and 4,000lb. wrought iron washers, $480, to Greenlie, Watt, & Co., New York.

Important Railway Connection.—The Pennsylvania Railroad Company, which has for years been endeavouring to secure a more direct entrance to McKeesport, has accomplished its purpose at last by the purchase of the McKeesport and Bessemer Railroad. This line itself is only an insignificant one, and is to extend but a few miles from McKeesport to the manufacturing town of Bessemer, where connection will be had with the Pittsburgh, Virginia, and Charleston division of the Pennsylvania road. The line will be constructed forthwith by the purchasers, and will form an important link in the Pennsylvania system, as it will materially aid in the handling of the enormous freight traffic offered by the iron and steel plants along the Monongobela River.

The Master Builders.—The National Builders' Convention has been holding its session during the past week in St. Paul, Minn. The principal subjects taken up were on lien laws and an eight-hour day. On the subject of liens the laws in the various States are entirely different, so that while in many places they are just and fair, in others they are defective. The attempt was made to appoint a committee to either pick out the best law or formulate a satisfactory one, and urge it on the State Legislatures. The matter was finally tabled. In dealing with the eight-hour question, the executive committee took no action as to the advisability or otherwise of an eight-hour day, but recommended that labour be hired and compensated by the hour, allowing each locality to determine for itself the length of the working day.

MESSRS. ARBEY'S TOOLS AT THE LATE PARIS EXHIBITION.

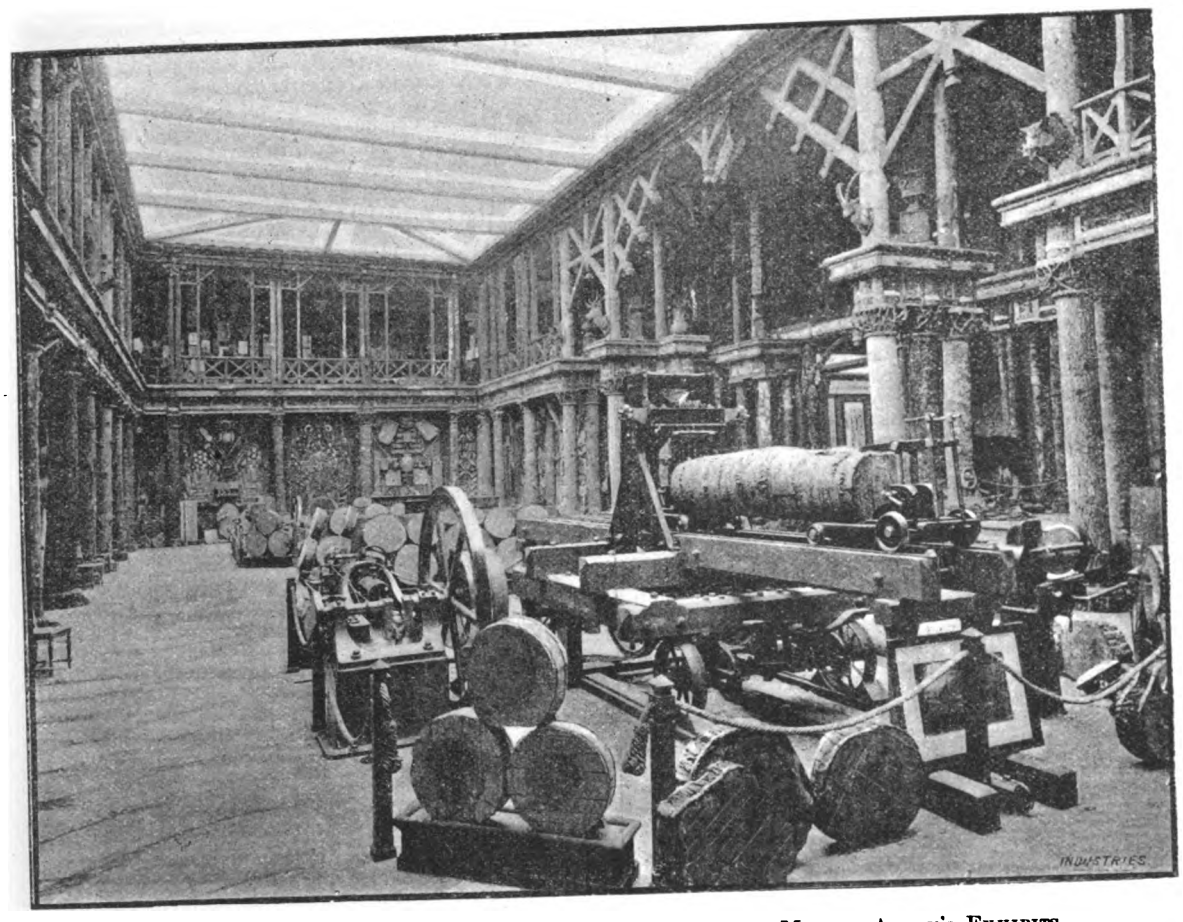

Fig 1.—The Pavilion of Woods and Forests, showing Messrs. Arbey's Exhibits.

MESSRS. ARBEY'S TOOLS AT THE LATE PARIS EXHIBITION.

Near the Trocadéro, and in the grounds, was a very artistic building erected by the Government Department of Woods and Forests, and containing a most interesting collection of woods and instruments used in forestry. This is shown in Fig. 1, above. There were three very instructive panoramas of forests and operations for maintaining them, as well as samples of the different woods, and the various articles made from each or the uses to which it may be put. In this pavilion Messrs. Arbey were invited by the Department to exhibit some of their special appliances for use in forests, and the interesting collection above mentioned was the result. The collection included a machine for sawing down trees, a machine for sawing logs in the forest or wood yard, a circular saw for use in the forest, and which may be drawn about by horses, and a log frame which may be moved from place to place by horses. Fig. 2, on page 180, shows the portable vertical log frame ready for working. When it is required to remove it to another place, two or four horses can be attached to the carriage, and it can be transported along the forest roads. About 5 h.p. are required to drive this frame. In many parts of France the owners of portable engines, which are kept busy driving agricultural machinery during the spring and summer, have nothing to do during the winter, and they take them about with these machines doing the kind of work for which they are adapted.

THE SOCIETY OF ENGINEERS.

The first ordinary meeting of the Society of Engineers for the present year was held on Monday evening, the 3rd inst., at the Town Hall, Westminster. Mr. Jonathan R. Baillie, the President for 1889, first occupied the chair, and presented the premiums of books awarded for papers read during his year of office, viz.:—The "President's Premium," to Mr. G. M. Lawford, for his paper on "Fireproof Floors"; the "Bessemer Premium," to Mr. Samuel Griffin, for his paper on "Modern Gas Engine Practice"; a "Society's Premium," to Mr. Henry Faija, for his paper on "Forced Filtration of Water through Concrete"; and to Mr. George R. Strachan, for his paper on "The Construction and Repair of Roads."

Mr. Baillie introduced the President for the present year (Mr. Henry Adams) to the meeting, and retired from the chair, receiving a hearty and unanimous vote of thanks for his services during the past year.

Mr. Adams then took the chair, and proceeded to deliver his inaugural address. After thanking the members for the honour they had conferred upon him in electing him to the presidential chair, he briefly alluded to the satisfactory position of the Society, which now numbers 417 members of all classes, and mentioned the loss by the death of Dr. Percy, and the addition of Earl Granville, Lord Armstrong, Lord Brassey, Sir Wm. Thomson, Mr. Wm. Anderson, and Mr. Benjamin Baker to the roll of honorary members. He commented on the principal points of the papers read during the session, and described the features of interest in the works visited by the members during the vacation, which included the East London Waterworks, the Sewage Outfall Precipitation Works at Crossness, the Central Station of the London Electric Supply Corporation, and the Foreign Cattle Market, Deptford. The President then referred to the progress of technical education, noticing particularly the work of the Science and Art Department, and that of the City and Guilds of London Institute, and incidentally gave some particulars of the City of London College, where he has been for 21 years the Professor of Engineering. Remarking that a wider field of enterprise than that contained within the shores of the United Kingdom was necessary for engineers, he gave statistics showing that about 30 per cent. of the English engineers were now practising abroad, and spoke of the advantages to be derived from the realisation of the idea of Imperial Federation. He then referred to the enormous strides being made in ocean navigation, and gave some particulars of the eight million tons of British shipping, with details of some of the recent performances. In connection with the Government expenditure on the increase of the Royal Navy, he said the contracts had been very fairly distributed over the great shipbuilding and marine engineering centres, and had given general satisfaction to those concerned. The extended use of mild steel and some of its disadvantages were noticed, and the President then passed on to a consideration of our fuel supply. He believed that the days of coal were surely numbered, and that it behoves us to seek other means of generating power and in the meantime to practise the greatest economy in the use of the mainstay of England's prosperity. Under the head of railways some figures were given, showing the vastness of the traffic upon them, and that, notwithstanding the rapidity of transit, according to the last statistics only one passenger was injured in 1½ millions, and not more than one in 80 millions was killed by causes beyond their own control. Particulars of present practice in compound locomotives were given, and the necessity for increasing the strength of the permanent way was stated. In connection with ordinary locomotives, Mr. Adams said he had recently made a public statement, which had been questioned, of the saving which one of the railway companies had obtained by the use of the "vortex" blast pipe, and he now appended a copy of the official statement, showing that by the alteration of 324 of the engines upon the London and South-Western Railway during the last four years, a saving of £48,461 had been effected. Several large bridges were described, the Forth Bridge, of course, occupying the place of honour, and references were made to many other engineering works and processes which have occupied public attention. In conclusion, attention was directed to the necessity for specialisation in the studies of engineers, the multifarious sub-divisions rendering it physically impossible for one man to thoroughly master more than one or two branches, and hence the necessity for the existence of such bodies as the Society of Engineers, where experience could be freely exchanged. A final exhortation to the members to wear out rather than rust out, brought to a close a very able and interesting address.

SHIPBUILDING NOTES.

The trial trip of the steel screw steamer "Malange" took place on the 5th inst. The "Malange" is built for the Mala Real Portuguese Company by Messrs Scott & Co., Greenock, and is fitted with a set of inverted direct-acting triple expansion engines, constructed for a working pressure of 160lb. to the square inch, and of 4,000 i.h.p. The cylinders are 31in., 50in., and 80in., with a stroke of 4ft. 6in. Her dimensions are: Length between perpendiculars, 350ft.; breadth, moulded, 42ft.; depth, 28ft. 6in.; gross tonnage, 3,543. She is fitted with two centrifugal circulating pumps with independent engines, supplied by Messrs. J. & H. Gwynne, of London. The electric light is fitted throughout the ship by Messrs. Parsons, Newcastle-on-Tyne.

On the 6th inst. Messrs. Russell & Co., Kingston Yard, Port Glasgow, launched a four-masted steel barque, named the "Strathgryfe." The vessel is built for Messrs. J. & W. Stewart, Greenock, and her dimensions are: Length, 270ft.; breadth, 42ft.; depth, 24ft. 6in.; net register, 2,200 tons.

The steel screw steamer of 4,000 tons, the "Palamcotta," was launched on the 6th inst. from the yard of Messrs. A. & I. Inglis, Pointhouse, Glasgow. The vessel was built for the British India Steam Navigation Company, London, and is intended for the Indian trade. She is provided with accommodation for first and second class passengers, and will be fitted with triple expansion engines of 3,000 h.p. She will also be supplied with electric light and hydraulic gear. Her dimensions are: Length, 360ft.; breadth, 42ft.; and depth, 29ft. 3in.

The steel screw steamer "Latona," built by Messrs. Russell & Co., Port Glasgow, was taken on her trial trip on the 8th inst. Her dimensions are: Length, 323ft.; beam, 42ft.; depth, 23ft. 6in. Two runs were made on the measured mile on the Clyde, and the speed obtained was 10¼ knots. The machinery worked very smoothly at 72 revolutions. The engines, which are by Messrs. Dunsmuir & Jackson, of Govan, have cylinders 24in., 39in., and 64in. diameter, with a stroke of 45in., and have been built under the superintendence of Messrs. Flannery & Blakiston, of Liverpool and London. The vessel is owned by Mr. G. M. Steeves, of Liverpool.

The "Normannia," a new Hamburg-American liner, was launched, on the 9th inst., from the Fairfield Shipbuilding and Engineering Yard at Govan. The launch was intended to have come off on Saturday, but it was found impossible owing to the dense fog which was over the river. The "Normannia" is provided with accommodation for 428 first-class, 170 second-class, and 700 steerage passengers. Her dimensions are: Length, 500ft.; breadth, 57ft. 6in.; depth, moulded, 33ft.; gross tonnage, 8,500 tons. She is guaranteed a speed of 19 knots, but there is every probability of her exceeding this. Twin screws have been adopted, as in most of the recent Atlantic liners, and her propelling machinery is designed to develop at least 14,000 i.h.p. The propelling bosses are of steel, and the blades of manganese bronze. Steam is supplied by nine double-ended steel boilers, each 16ft. by 18ft., and the shafting, which is made by Messrs. Jno. Brown & Co., Sheffield, is entirely of steel. She is fitted with triple-expansion engines, with cylinders 40in., 67in., and 106in. diameter respectively, with a stroke of 5ft. 6in.

Digitized by Google

THE "Alfred Dumois," a steel screw steamer, was launched on the 11th inst. by Messrs. Blackwood & Gordon, Port Glasgow. The vessel has been built to the order of Mr. Jacob Christensen, Bergen, and is intended for the fruit trade between New York and the West India Islands. It is a remarkable fact that this trade, at one time largely in the hands of Scotch shipowners, has been for some time drifting into the hands of Scandinavian owners, till now they own the bulk of the tonnage engaged in the trade.

Notices of Meetings.

THE INSTITUTION OF ELECTRICAL ENGINEERS.—Thursday, February 27th, 8.0 p.m. Discussion on the following papers: "The Theory of Armature Reaction in Dynamos and Motors," by James Swinburne, and "Some Points in Dynamo and Motor Design," by W. B. Esson.

THE INSTITUTION OF CIVIL ENGINEERS.—Friday, February 21st, at 7.30 p.m. Students' meeting. Paper to be read: "Some Types of American Locomotives and their Construction," by C. N. Goodall, Stud.Inst.C.E. Tuesday, February 25th, at 8 p.m. Ordinary meeting. Discussion upon the papers by Messrs. Hart, Orange, and Turner, on the Shanghai, the Hong-Kong, and the Yokohama Water Works.

PRICES CURRENT, 19TH FEBRUARY, 1890.

Quotations at per ton, unless otherwise specified.

METALS.

Spelter: Ordinary	£23	15	0	to	£24	15	0
Copper: British Cakes and Ingots	56	0	0	„	57	0	0
„ Chili Bars, G.O.B.'s	47	15	0	„	48	2	6

„ Manufactured (strong)	64	0	0	„	.....		
Lead: Common Pig	13	15	0	„	14	0	0
„ English Sheet	14	5	0	„	14	10	0
Tin: Straits	91	5	0	„	91	12	6
„ Australian	91	0	0	„	91	10	0
„ English Ingots	97	0	0	„	.....		

Messrs. Carrick & Brockbank, Manchester, report as follows:—

COPPER: Since our report of the 12th the market for Chili bars has been irregular, and values are now higher. A better demand set in at the end of last week, and prices advanced from £46 17s. 6d. to £47 5s. on the 12th to £48 5s. to £48 12s. 6d. on the 17th, but have since receded, being quoted to-day £47 15s. to £48 2s. 6d. In manufactured the demand continues slack, and the official quotation is now £64 for strong copper.

TIN has been very variable during the week. On the 13th prices were £90 7s. 6d. to £90 15s. cash, advancing on the 17th to £92 to £92 10s. An easier feeling has, however, since prevailed, to-day's quotations being £91 5s. to £91 12s. 6d.

LEAD continues very flat, and prices are decidedly easier.

SPELTER is much stronger and in better demand, with every prospect of still higher prices, as stocks are small. The late depression was brought about by the reselling of stocks by weak holders. These lots having been worked off, the market has rallied, and the price is advancing daily.

ANGLES, PLATES, BARS.

Messrs. G. Bailey Toms & Co., London, quote as follows:—

Messrs. S. W. Royse & Co., Manchester, report as follows:—

CHEMICALS: There have been few changes of note during the past week. Business in chemicals is, however, now quieter than it has been for some time, but prices remain fairly steady. The demand for caustic soda has slackened, and prices are easier. Bleaching powder has a good inquiry at steady figures. Soda ash still scarce, and the advance in soda crystals is maintained. Sulphate of ammonia has steadied, but not much business is passing. Other ammonia salts are in moderate request. Benzoles are easier. Carbolic acids still quiet. Solvent naphtha in demand. Makers of oxalic acid are busy, but prices remain low. There is less inquiry for green copperas. Sulphate of copper is very scarce on spot. Lead salts quiet, but steady.

FOREIGN TELEGRAPHIC ADVICES.

(From our own Correspondents.)

PARIS, Feb. 20.—*Iron.*—The tone of the iron market generally is weaker. Business here is very slack, and merchants find it hard to maintain the price of bars and joists at 172s. The markets of the provinces are still moderately strong in tone; but they have lost the buoyancy which characterised them a few weeks ago. Buyers hesitate. Sellers, however, having their order-books well filled, manifest no disposition to force the market.

Metals.—Business in the metal market continues to shrink. Consumers of copper are buying but little, and no rigging of the market will frighten them into dealing beyond the needs of the moment. Prices are weak. The markets for tin, lead, and zinc exhibit the same features which characterised them a week ago. The declining tendency is, however, but feebly marked.

BERLIN, Feb. 20.—*Bourse.*—The last week has been a period of fluctuations in the market for industrial securities. Among investors, however, sellers are still more numerous than buyers, the threatened strike of colliers having shaken confidence. Shares in iron and steel companies maintain their position in the market, but colliery shares are lower.

Iron.—Though business in the iron market is not particularly brisk just now, sellers have not hesitated to advance their rates. The minimum price for Upper Silesian bars is 205s., but dealings are recorded several shillings higher. There is a better demand for joists and sheets.

Metals.—Business in the metal market is quieter, and prices have further declined. Mansfeld refined copper, £59 10s. to £60; English brands, £57 to £59. Tin has receded a point: Banca, £102 to £104. Lead is tending in favour of buyers: Clausthol refined, £16 to £16 10s. Spelter, too, has receded slightly: Silesian, W.H. brand, £26 10s. Antimony regulus firmer, at £79 to £82 English.

BRESLAU, Feb. 20.—*Coal.*—The prices of coal at the fiscal collieries have been advanced 1s. to 1s. 4d. a ton. As a reduction is usually made on March 1st for the summer months, this advance is significant. The supply of coal for metallurgical purposes is increasing.

Iron. The market is active all round. The blast furnaces are now producing more abundantly, thanks to a better supply of coal. The price of grey No. 1a pig remains at from 85s. to 90s. Boiler and common plates are in strong demand, the former at 250s. to 260s., the latter at 230s. Sheets are quoted 265s. The minimum for bars has again been raised.

Metals.—There are no signs of weakness in the metal market here. Spelter remains unchanged in price. The production is large, but barely sufficient to meet the demand. There are no stocks. Lead maintains its price firmly.

DÜSSELDORF, Feb. 20.—*Coal.*—No change worthy of note has occurred in the market for coal within the last few days. The recent advance is readily paid. Iron masters are now getting a more abundant supply. Coking coal from 14s. to 16s. at pits. Blast-furnace coke from 29s. to 31s. at the ovens. Briquettes are in strong demand at from 16s. to 18s.

Iron.—Business in pig iron is somewhat slack, but prices have lost none of their firmness. Spiegel pig, ordinary, 103s.; Rhenish-Westphalian forge, 93s.; Siegen forge, 94s.; white steel pig, 93s.; foundry, No. 1, 102s.; Thomas, 80s. to 82s.; Bessemer, 95s. to 96s. The market for finished iron and steel is less animated generally, but common plates and sheets are in strong demand. Prices are unchanged.

CHARLEROI, Feb. 20.—*Iron.*—The recent relapse in the English market has knocked out most of the life from the market here. To-day, however, matters look a little more cheerful. Buyers are not, perhaps, dealing more freely, but they are inquiring more earnestly. Prices are firm. Bars, No. 2, are quoted 152s.; joists, 144s.; angles, No. 3, 152s.; plates, No. 2, 220s.

Glass.—The proposed syndicate for the sale of window glass in the markets of the United States of America is on the point of being established, all the difficulties which hindered its formation having, it is said, been removed.

GHENT, Feb. 20. *Flax and Yarns.*—The supply of home-grown flax is large and the demand moderately brisk. Prices unchanged. Large dealings are taking place in Russian flax at lower prices. There is a fairly active demand for yarns; but sellers have to make concessions in the case of large orders. The high prices asked for cotton yarns restrict business within very narrow limits.

PREVENTION OF FIRE.—An invention for the prevention of fire in cotton cargoes is attracting some attention. Jute packing is objected to on two grounds. It is woven loose, and therefore does not completely cover the cotton bale; and, besides being of an inflammable nature, it is rendered easily combustible on account of oil being used in its preparation. Mr. Samuel Quilliam, Liverpool, has patented an invention which it is claimed obviates the two difficulties referred to. Mr. Quilliam's improvement, it is said, gives a non-inflammable close woven bagging, which can be produced at a little over the cost of the bagging now in use.

AN IMPROVEMENT IN SLIDE VALVES. Mr. Lyon, of Messrs. Gourlay & Co., Dundee, has patented a new arrangement of slide valve in connection with marine engines, with the object of getting rid of the difficulty of cushioning the low-pressure piston. The arrangement is thus described:—"The exhaust ports are so arranged that during the period of release the communication with the condenser is closed and opened to the heater. The steam, which would in ordinary circumstances rush to the condenser, is therefore trapped and utilised to cushion the piston and to heat the feed water." It is claimed that besides making the engine work more smoothly this arrangement effects a saving in fuel of about 7½ per cent.

HOME INDUSTRIES.

LONDON 20TH FEBRUARY, 1890.

THE MONEY MARKET.—In the earlier part of the week a strong impression prevailed, chiefly in Stock Exchange circles, where the change would be welcome, that the Bank directors would lower the official rate to 5 per cent. The belief was fostered by the purchase of gold by the Bank on Monday and by arrivals of sovereigns from Paris later on. But neither cause was sufficient to justify the assumption, for purchases of bullion do not affect the relations between liabilities and reserve, and the arrival of gold from Paris was proof that the high rate was achieving what it was intended to do. The money market set no store on the rumours of a reduction in the official minimum, and rates for loans and discounts have remained firm. The stock markets are still listless. The slight improvement in the monetary position has told in favour of Consols, and the investment of dividend money has given a fillip to substantial railway stocks. Still, home railways have been dull, speculative purchases of Chathams and Metropolitans being the most marked feature. American railways have been hardly looked at, though the long-talked-of funding of the stocks of the Pacific lines has been used as an argument for purchases. Canadian lines are neglected, and Mexican Railway stocks, though a rise in silver has stiffened quotations, are out of favour. In the foreign department business is restricted, Turkish stocks alone showing consistent vitality. Nitrate securities, after a feeble rally, have relapsed, and mining quotations are tending downwards.

COMPANIES.—The following companies have been registered since our last report:—The Summervale Mill Co., Ld., with a capital of £22,500; The Hull Enamelled Slate and Marble Co., Ld., with a capital of £8,000; The Hargher Clough Room and Power Co., Ld., with a capital of £15,000; The Patent Rivet Co., with a capital of £60,000, to carry on business at Smethwick; Pearce & Co. (Cardiff), Ld., with a capital of £35,000, to carry on the business of brewers; The Lane-Fox Electrical Co., Ld., with a capital of £100,000; The Golden Valley Mines, Ld., with a capital of £60,000, to acquire mines in the Barberton De Haap Goldfields, Transvaal; The Fareham Electric Light Co., Ld., with a capital of £5,000; The Button Machine Manufacturing Co., Ld., with a capital of £25,000, to acquire a certain patent for button machines; The Heavitree Brewery, Ld., with a capital of £65,000; The Iron Minerals Syndicate, Ld., with a capital of £10,000, to carry on the business of proprietors of mines, &c.; The South Wales Whitworth Mineral Estates, Ld., with a capital of £50,000, to carry on the business of colliery proprietors; The Bradford Manufacturing Co., Ld., with a capital of £41,000, to carry on the business of combers, doublers, spinners, &c.; The African Prospecting Syndicate, Ld., with a capital of £100,000, to acquire claims, &c., in Africa; The Hollingreave Manufacturing Co., Ld., with a capital of £5,000, to carry on business of cotton manufacturers; The Sheriff Hill Colliery Co., Ld., with a capital of £30,000; The Leeswood Spelter Co., Ld., with a capital of £5,000.

COPPER.—James Lewis & Son report that the "stocks of copper continue steadily to decrease, the reductionin the past fortnight being 1,978 tons. Realisations of good merchantable copper falling due, bought by Scotch and other speculators three months previously, combined with the large number of warrants available from the sale in January of 4,000 tons Chile bars by one of the French holders and the dearness of money, caused the market, in sympathy with a further fall of 4s. per ton in pig iron warrants (making the total fall in rather less than a month over 20 per cent.), to give way, and sales of cash G.M.B. were made from £48 15s. on the 3rd inst. to £46 15s. on the 11th the fall on this day being 22s. 6d. per ton. With less pressure to sell and more desire to buy, values advanced on the 13th and 14th inst. from £46 17s. 6d. to £47 17s. 6d. for cash and from £47 5s. to £48 10s. for three months' prompt. On the 17th the market was irregular, but good business was done at £48 12s. 6d. to £48 2s. 6d. for cash, and £48 17s. 6d. to £48 12s. 6d. for prompt, closing with buyers at the latter figures. A considerable portion of the warrants put on the market by the French bankers have now been absorbed by consumers, and in view of the sharp fall in values caused by the sale of a large quantity at one time, they will doubtless act with more caution in future."

GAS AND ELECTRICITY.—At the half-yearly meeting of the Gas Light and Coke Company, held recently, the Chairman, Colonel Makins, M.P., stated that he did not think the house owners of London, who were mostly leaseholders, would go to the great expense of an installation of the electric light when they could get gas without that expense. This attitude of Colonel Makins is exceedingly similar to that of stage coach owners and posting house proprietors in the days when railways were in their infancy. The general public, they said, were not likely to give up the safe and pleasant four-in-hand to risk life and limb on the iron road.

THE SPHINCTER GRIP ARMOURED HOSE.—The Sphincter Grip Armoured Hose Company, Limited, 9, Moorfields, E.C., have been awarded a bronze medal (being the highest award given for hose exhibit) for their patent sphincter grip hose, at the Brighton and Hove International Exhibition. No other armoured hose has, we understand, secured an exhibition award. Awards have been made at the Paris Exhibition, 1889, the Birmingham Electrical and Industrial Exhibition, and the American Exhibition, London, 1889. The company have added five new patented improvements to their machinery since they first placed this hose on the markets. The hose is in extensive use at the various Departments of Her Majesty's Government, the Continental and Colonial Governments, railway, steamship, and dock companies, &c.

ARTIFICIAL STONE.—The Indurated Stone Company, Limited, are removing their offices from 13, Victoria Street, Westminster, to their works in the Glengall Road, Millwall. The company are very busy manufacturing artificial paving stones and sewer pipes. They are extending their works, having taken in a large piece of ground, upon which they propose erecting a galvanised iron shed and improved machinery for the manufacture of their specialties.

SANITARY ENGINEERING.—Messrs. Baird, Thompson, & Co., ventilating, sanitary, heating, and lighting engineers, of London and Glasgow, have opened new showrooms at 165, Queen Victoria Street, E.C. Alterations are being made to St. John's Church, Carlisle, and the ventilation improved. Baird, Thompson, & Co.'s new and improved self-acting exhaust ventilator has been adopted for the extraction of the vitiated air, and their latest improved form of air-inlet "panel ventilator" is used for the introduction of the fresh air without draughts.

NEW TELEMETRICAL THEODOLITE.—Mr. W. F. Stanley has introduced a new patent theodolite possessing many noteworthy improvements. A tribrach stage is employed instead of four parallel screws, which permits the instrument being used on a wall without the legs, and prevents all possibility of straining the centre. The instrument has a mechanical stage for shifting the centre with exactness over the desired spot. The telescope supports and the centre are in one casting, and the size of the bearing on the centre has been increased. Instead of webs, which are a constant anxiety to the engineer or surveyor, platinum-iridium points are substituted. These neither rust nor break, and allow of any dust being brushed off with a camel hair pencil without interfering with the adjustment. The eye-piece is also fitted with two vertical adjustable points for measuring distances. A long trough needle is supplied with each instrument in place of the usual small circular compass. The head of the tripod is of an improved form, giving greater rigidity.

MANCHESTER, 20TH FEBRUARY, 1890.

THE LIMITED LIABILITY ACTS.—A conference of representatives of Northern Chambers of Commerce was held on the 14th inst. in Manchester, at which resolutions embodying the proposed amendments to the Companies Acts were adopted. The amendments suggested were as follows:—First, that two registrations of every company should be made, one provisional and one complete; second, that before complete registration 75 per cent. of the nominal capital should be subscribed and allotted; third, that 10 per cent. should be paid on application and 10 per cent. on allotment; fourth, that the nominal capital of any industrial company shall not be less than the value of the fixed and working plant; fifth, that before allotment a meeting of applicants should be convened, which may appoint a committee of five, exclusive of the promoters or other interested persons. The committee is to have the power of examining all documents and contracts, present or proposed, between the vendors and the proposed company; sixth, that a copy of the memorandum of association, the names, addresses and occupations of the promoters or provisional directors, and the names and descriptions of all persons entitled to any commission, brokerage or agency charges and the amount of these, should be included in every prospectus; seventh, that the balance-sheet of every company shall state the annual rate of depreciation which has been charged and be accompanied with a detailed statement of all items added to the capital account since the preceding balance-sheet. Power is given to penalise auditors who do not certify the deduction of the depreciation, and a similar power is given with regard to the signing of balance-sheets by directors. Sir W. H. Houldsworth, M.P., and Mr. Isaac Hoyle, M.P., were empowered to draft a Bill upon these lines.

BRUNNER, MOND, & CO., LIMITED.—The half-yearly report of the directors of this company shows that a profit of £120,640 had been made, out of which a dividend of 7 per cent. per annum on the preference and 30 per cent. on the ordinary shares is proposed to be paid. In addition to this £2,500 was written off patents account, £20,000 placed to a suspense account to provide for remodelling a part of the plant, £6,500 written off the lands account, and a balance of £13,806 carried forward.

PACKING OF SURAT COTTON.—The Liverpool Cotton Association have adopted two new bye-laws with reference to Indian cotton. The first provides that this class of cotton is not to be considered merchants' shipment unless it has been sampled and examined by the European firm shipping it. The second empowers either buyer or seller to remove a hoop and to take samples from both sides and the middle of the bale, in equal quantities, in order to test the condition of the packing. Samples for sale or arbitration are to be drawn only from the fair side. The examination is not to invalidate any subsequent claims for false packing.

AMERICAN LIFTS.—At the annual dinner of the Manchester Association of Engineers the Mayor announced that the Corporation of this city had resolved to put an American lift into the Victoria Buildings, and twitted English engineers with not being able to compete with Americans. The statement was received with dissenting cries, and the President subsequently said that if English firms were fairly treated they were quite able to construct lifts equal to those of American make.

AIR PROPELLER TESTING.—The Blackman Air Propeller Company at their Manchester stores have fitted up a simple contrivance by which they can ascertain the relative merits of any make of propeller. It consists of a short length of tube of large diameter with both ends open. Attached to each end are light frames containing suitable bearings for a shaft extending the full length of the tube, and fitted with a shank at each end, on to which the propellers can be firmly fixed. Sliding freely upon the shaft and fitting the tube is a diaphragm, dividing the tube into two parts. When the propellers are fixed the shaft is driven by a strap from a gas engine, and as one of the propellers is the opposite hand to the other, air is forced into the tube from each end. The relative efficiencies of the different makes is determined by the position the diaphragm assumes in the tube. If the powers are equal it remains midway; if not, it is forced to one end. We saw several types tested against the Blackman, and in every case the diaphragm was forced to the end of the tube furthest from the latter. By means of a gas meter of suitable construction the actual consumption of gas by the engine with each propeller when running can be gauged, but we did not see this point actually tested.

THE LINEN AND JUTE TRADES.—Manufacturers across the border and in the North of Ireland continue well engaged on orders placed some time ago and on new contracts, but producers in the North of England are not so busy as could be wished, power looms not being fully engaged, while the old hand-loom industry seems to be dying out altogether. Brazilian and Portuguese troubles have affected business somewhat, but not to a sufficient extent to have any perceptible influence upon the commerce of the country generally. Firms engaged in the shipment of drills to South America of course find trade slower owing to the political disturbances there, and the sensationally high rates of exchange have borne very heavily upon importers in South America, with the result that remittances are being purposely delayed until they can be made without so much loss. Scotch makes of bleached fringed tray cloths have met with a good inquiry, and the business in these elegantly designed fabrics promises well for the future. Fancy check hollands in greater widths than usual, suitable for pinafores and dresses, are much more in favour now with the public, to judge from the orders placed by the wholesale distributors here, and manufacturers would do well to note this fact. Stair linen damasks and crumb-cloths are not in such demand as formerly, and the old huck towel trade is a decaying one. The fancy jute trade is unchanged. Plain varieties move off steadily, and there is a good all round demand for linen threads.

GLASGOW, 20TH FEBRUARY, 1890.

SHIPBUILDING.—Orders continue to be scarce, almost none of any consequence having been booked by any of the Clyde shipbuilders for about three weeks. This lull is probably due to the falling away of freights, especially homewards. The increased cost of material and labour, and the large amount of work on the stocks in the yards, have combined to produce this depression. Freights for sailing ships have suffered a drawback as well as steam freights, and thus there is little encouragement at the moment to place new orders.

ENGINEERING.—The well-known engineering firm of Messrs. P. & W. Maclellan has been formed into a limited liability company. P. & W. Maclellan, Limited, will be the new style of the firm. The capital will amount to £300,000 in £10 shares, 16,000 of these being 6 per cent. cumulative preference shares and 15,000 ordinary stock. The preference shares are to be entitled to receive half the balance of profit after 6 per cent. has been paid on the ordinary stock. £150,000 is also offered in 5 per cent. first mortgage debentures, the interest being guaranteed by the Mortgage Insurance Corporation (Limited). The prospectus states that the business was established in 1811, that the number of employés is 2,000, and that the annual turnover is about a million sterling. It is also stated that there is enough work on hand to keep the existing powers of production going for a year. The purchase price, including land, buildings, plant, goodwill, patent rights, &c., is to be £350,000. Messrs. Turquand, Youngs, & Co. report that the average annual profits for the past five years were more than sufficient to pay 5 per cent. on the amount issued as debenture stock, together with 6 per cent. on both preference and ordinary shares. The list opens to-day (Thursday) and closes to-morrow (Friday).—Mr. Alexander Aitchison, engineer of the Steel Company of Scotland, has gone to a similar appointment at Messrs. Palmer & Co.'s works at Jarrow-on-Tyne.

PIG IRON.—Although the pig iron market is still labouring under the weight of large quantities of high-priced contracts coming due every day till the end of this month, confidence has been to a great extent restored by seeing even the heaviest settlements going on day by day without any trouble. The greatly increased cost of production seems to make 52s. a safe enough basis of operation, and some good buying has been done on the strength of it. Cleveland and hematite have been affected even more than Scotch by the prospective scarcity and demand of coke. This week the market was strong, and in the early part of

Digitized by Google

the week had reached a point which marked an advance of about 3s. on Scotch, 4s. on Middlesbrough, and 5s. on hematite above the lowest points touched during the late depression.

(From our own Correspondents.)

LIVERPOOL, 19th February, 1890.

Liverpool Overhead Railway.—Considerable progress has been made in the construction of this railway. The foundations of a hundred piers have been laid at the north end and work has commenced at the south end. The columns and girders are being constructed, and in a short time the contractor hopes to be able to erect them at the rate of two spans of 50ft. per day. The equipment of the line would be of the lightest kind, and would resemble more an overhead tram-line than a railway. The motive power is to be electricity, but on account of the rapid strides of this science, the particular form of motor will not be decided upon until the last moment. The specified time for completion of the line is two years, and there is every prospect of the work being then completed.

The Dinsmore Gas Company.—At the annual meeting of the shareholders of this company, held on Monday, it was stated that, although there had been considerable delay in the operations, the directors were quite satisfied as to the ultimate success of the process. Satisfactory reports had been received from Mr. Newbigging and from Professor Foster, and the process was in operation at twelve gas companies or corporation works. Mr. Carr, gas engineer, Widnes, stated that the process had effected an annual saving of £1,700, and that the illuminating power had been increased from 19 to 20 candles. Mr. Pritchard, of the Huyton Gas Works, stated that by adopting the process the illuminating power had been increased 20 per cent.

New American Steam Line.—It is announced that Mr. Ingalls, President of the Chesapeake and Ohio Railroad, has been granted a charter by the Virginia Legislature for the establishment of a line of steamships between New York and Liverpool, and that the ships are to be built in England.

Live Stock and Fresh Meat Imports.—During the past week 1,107 cattle and 12,023 quarters of beef were landed in Liverpool, showing a decrease of 13 cattle and 3,102 quarters of beef from the amounts of the previous week.

SHEFFIELD, 19th February, 1890.

Coal and Coke.—House coal is not selling very briskly just now owing to the mild weather; its average price is from 12s. to 15s. per ton, according to quantity. Coke of all classes is in excellent demand. The hard North of England coke is in great request for steel melting purposes, while the smaller varieties used for stoves and smithies find a steady and increased sale.

Iron and Steel.—The iron market has assumed a firmer tone. Local manufacturers report a good volume of business. Merchant bars in standard sizes of treble best quality are still imported to a large extent. Further large orders for armour plates have been received by Messrs. Cammell & Co. and Messrs. John Brown & Co. The former firm will supply plates to the "Hood," building at Chatham Dockyard; the "Royal Sovereign," building at Portsmouth; the "Royal Oak," building by Messrs. Laird Brothers, Birkenhead; and the "Ramillies," building by Messrs. J. & G. Thomson, Glasgow. Messrs. John Brown & Co. are to supply armour for the "Repulse" and "Renown," building at Pembroke Dockyard; also the "Resolution" and "Revenge," which are to be constructed by Messrs. Palmer's Shipbuilding Company, Jarrow-on-Tyne. It is expected that this work will occupy the above firms for about two years. Messrs. Vickers, Sons, & Co., Limited, of the River Don Works, have secured a large contract for the thinner all-steel armour plates up to 4in.

LEICESTER, 19th February, 1890.

Wool Spinning and Yarn Trades.—No great variations are apparent in the local wool market. The tone remains cheerful and healthy. There is a large consumption and stocks are generally low. The business done is for present wants. Spinners are busy. Though the new orders booked are light, there are enough on the books to keep the mills going for some time to come.

Hosiery Trade.—For the time of the year a good trade is being done. There are some very good Government contracts for the army and navy now on hand, and they will give much employment for some time to come.

Boot and Shoe Trade.—Business in this industry still flourishes. All the houses are working up to their full capacity, and several of the largest are working overtime.

SWANSEA, 19th February, 1890.

Tinplates.—Several tinplate works have already temporarily stopped, as they cannot pay the price of steel bars and manufacture plates without a positive loss. On the completion of the balance of unexecuted orders several other makers mean to adopt a similar course. Notwithstanding this unsatisfactory immediate outlook, every confidence is retained in the future of the trade, and capital continues to flow into this industry. The Port-Talbot Tinplate Company has been registered, with a capital of £35,000 in £35 shares, and the Cardonnel Tinplate Company, with a capital of £20,000 in £50 shares. The tender of Mr. A. George, of Neath, for the erection of the Baglan Bay Tinplate Works has been accepted. So enormously has the traffic in tinplates increased that the executive committee of the Swansea Harbour Trust recommend laying down additional sidings at the Prince of Wales' Dock at a cost of £1,600. We quote Bessemer bars, £7 15s., and Siemens, £8 2s. 6d.; tinplates, Bessemer cokes, 16s. 6d., Siemens coke finish, 17s. 6d. per box, common sizes.

Companies and Dividends.—The two great railway companies interested in this district—viz., the Great Western and the London and North-Western—have both declared dividends at the rate of 8 per cent. per annum for the past half-year. This leaves room to hope that the Great Western Railway will be mindful of its interests in Swansea, where the shipments of coal have been diminished by 20,000 tons in one month owing to the war of rates waged by the railways converging on Cardiff. Colliery proprietors have notified purchasers that they cannot in future ship coals at Swansea except at an advance of 6d., and in one case of 1s., per ton on ruling prices. The Rhondda and Swansea Bay Railway, the completion of which has been entrusted to Messrs. Lucas & Aird, who undertake to finish their work about the middle of May, will help to restore this lost trade, especially as its mineral traffic continues to increase on the section of the line already open, and in view of the fact that the junction with the Taff Vale Railway has been effected. The directors have been able to recommend a dividend at the rate of 5 per cent. on the preference capital, and 2 per cent. on the ordinary shares. The shareholders in the Brittany Steamship Company, Limited, who have received 26 per cent. for the year, are to be congratulated, and not less so those of the Bristol and South Wales Railway Wagon Company, who receive 10 per cent., after having had a similar dividend for the last twenty years. The South Wales Engineering Works and Ship Repairing Company have also paid 10 per cent. for the year.

BARROW-IN-FURNESS, 19th February, 1890.

Iron.—A better tone is imparted to the hematite pig iron trade this week by reason of the improvement which has just taken place in warrants. The latter have advanced during the week to the extent of 3s. per ton, and are now quoted at 67s. 6d.; but makers are still asking 82s. for mixed numbers of Bessemer net f.o.b. The result is that little new business has been done during the week. Makers are very busy, and are full of orders for many months to come.

Steel.—There is a quieter tone in the steel trade consequent on the expectations of reduced prices. There is a good inquiry for steel rails, but not any disposition to place orders. A large inquiry is also experienced for steel shipbuilding material. The tinplate trade is quieter, and the demand is less.

The Foreign Ore Trade.—Owing to the scarcity which has arisen in the supply of native hematite ore, large importations are now being made of Spanish ore from Bilbao, Carthagena, and elsewhere, and this has consequently imparted considerable activity to the shipping trade of the North-West Coast. Spanish ore is quoted at from 16s. 6d. to 17s. 6d. per ton delivered, and prices are buoyant. Advices from Bilbao say the supply of ore is not equal to a maintenance of the present rate of exportation.

A Successful Mining Company.—The Hodbarrow Mining Company is at present engaged in the building of a sea-wall or embankment in the Duddon estuary, with a view to keeping the water out of the workings of their hematite mines, which are the richest in the world. The cost of this embankment will be from £170,000 to £200,000.

Shipping.—The shipping returns for the West Coast ports for the past week show an improvement on 1889. The amount of pig iron and steel shipped during the week represented 21,939 tons, compared with 16,614 tons in the corresponding week of last year, being an increase of 5,325 tons. The total shipments to date, however, show a falling off as compared with last year.

MIDDLESBROUGH, 19th February, 1890.

Pig Iron.—There was a large attendance at the weekly market held on 'Change yesterday, and there was a good deal of business done. Buyers are eager to be supplied in the prospect of a busy spring. Prices advanced slowly but steadily. The quotation now is 55s. to 55s. 3d. per ton for prompt delivery of No. 3 G.M.B., and 55s. 6d. per ton for delivery over the next two months. Makers, however, still hold out for 60s. and upwards, and will not part with grey forge under 57s. per ton, as they have the most of it on their hands. Warrants are 55s. 1d. cash buyers and 55s. 3d. buyers. Everything denotes a steady rise, and as yet there is no attempt at speculation. The stock in Connal's store on Monday, the 17th inst., was 181,264 tons, against 182,523 tons on the previous Monday.

Shipments of Pig Iron.—The dead season is gradually coming to an end, and shipments are beginning to increase. The outlook in this direction is very promising indeed, except as regards Scotland. The shipments for the present month, up to the 17th inst., were 28,914 tons, as against 23,173 tons over the similar period last month, and 27,938 tons over the same time in February last year. Germany and Holland are taking more, as well as other foreign countries. There is, indeed, every indication of increased shipments as the spring advances.

Manufactured Iron and Steel.—In the finished iron trade there is no change, but this is not likely to continue if pig iron goes on advancing. There are more inquiries and greater desire to have orders placed. Iron ship-plates are at £7 10s., angles, £7 5s., bars, £7 10s. per ton f.o.t. less 2½ per cent.; steel ship-plates, £8 10s., angles, £8 5s., rails, £6 12s. 6d., sleepers, £7 10s. per ton, less the usual discount.

Coal and Coke.—The threatened strike is causing some uneasiness, and there is good reason for such amongst the blast furnace owners, who could not go on for long. There is a feeling, however, that all will come right. The threat has had its effect in stiffening prices and pressure for delivery. All kinds of coal are in brisk demand except households, which are somewhat dull from the mildness of the season. Coke maintains its price at 27s. to 27s. 6d. delivered.

NEWCASTLE, 19th February, 1890.

Steel and Iron Trades.—In these industries there is considerable uncertainty just now, the impending labour troubles in the coal trade and the marked falling off of orders in the shipbuilding trade being among the chief disturbing elements. The works, however, are generally kept busily going, the briskness in both the iron and steel departments of the Palmer's Shipbuilding and Iron Company's works at Jarrow being particularly noticeable. This firm, though being themselves among the largest consumers in the country, are still, owing to their unique resources, able to supply a good proportion of the material used by the other shipbuilding, boiler building, and bridge building firms in the district.

Shipwrights' Wages.—The shipwrights employed in the various shipbuilding yards on the Tyne have given the employers notice that they require an advance of 3s. per week in the wages rate, to commence on March 13th. A meeting of the employers will shortly be held, to consider and decide upon the application.

Engineering.—Messrs. Ernest Scott, Close Works, Newcastle, have received orders for some forty pumps, of the Admiralty type, for use on board the new cruisers now in course of construction at the principal shipbuilding yards on the Tyne and other rivers. They have also several orders for the Priestman oil engine. In their electrical department exceptional activity exists, the manufacture of dynamos and arc lamps of various sizes being carried on on an extensive scale. Among the principal installations in hand may be mentioned the lighting of a large steamer intended for employment in the frozen meat trade. The firm have also an order for the complete installation of a frozen meat store in the Argentine, and are about to send out a staff of skilled workmen to fit up the plant.

The Coal Trade.—The somewhat strained relations now existing between employers and employed are causing some anxiety in commercial circles as to the future course of affairs. The shipments of coal and coke at Tyne Dock for the week ending February 15th amounted to 103,129 tons, being a decrease as compared with the shipments for the corresponding week last year of 834 tons.

Chemicals.—The chemical trade of Tyneside is affected by a dread of labour difficulties interfering with the output of manufacturers. The workmen of Messrs. Tennant & Parts, who demanded an advance of wages, and who were refused any increase in the amount of their remuneration, have now suggested that their case be referred to arbitration. The employers have agreed to submit their case to the arbitrament of a local solicitor. The alkali makers of the district have now formed an association for the purpose of resisting what they consider to be unreasonable demands on the part of the workmen.

BELFAST, 19th February, 1890.

Dock Labourers' Strike.—This strike still continues—at least in name—and the work of discharging vessels is being done by means of non-society men without any interference from the men on strike. Several of the latter have started work again, and it is thought that the strike cannot last much longer, and that the power of the Union is almost completely broken.

Boiler Making.—Several large orders are now in hand for land boilers. Two very large boilers have just been completed by Messrs. Victor Coates & Co. for the Hilden Thread Factory. Much more work of this sort might be done in this district if makers were a little more enterprising.

Shipbuilding.—The stocks still continue full, but orders are not coming forward as they were some time ago. Workmen are now becoming more plentiful, and are working steadily. Ship carpenters have been granted an increase of 1s. per week. Several large vessels are ready for launching, and others are in an advanced state of completion.

Linen Trade.—The markets continue very slack, and the turnover is very small. Contracts are running out, and as they do so buyers find less difficulty in making purchases to suit their ideas. The stock of warp lines is very small, and prices are firm. Tows also maintain their old values. Manufacturers of special makes of cloth hold good contracts at fair prices.

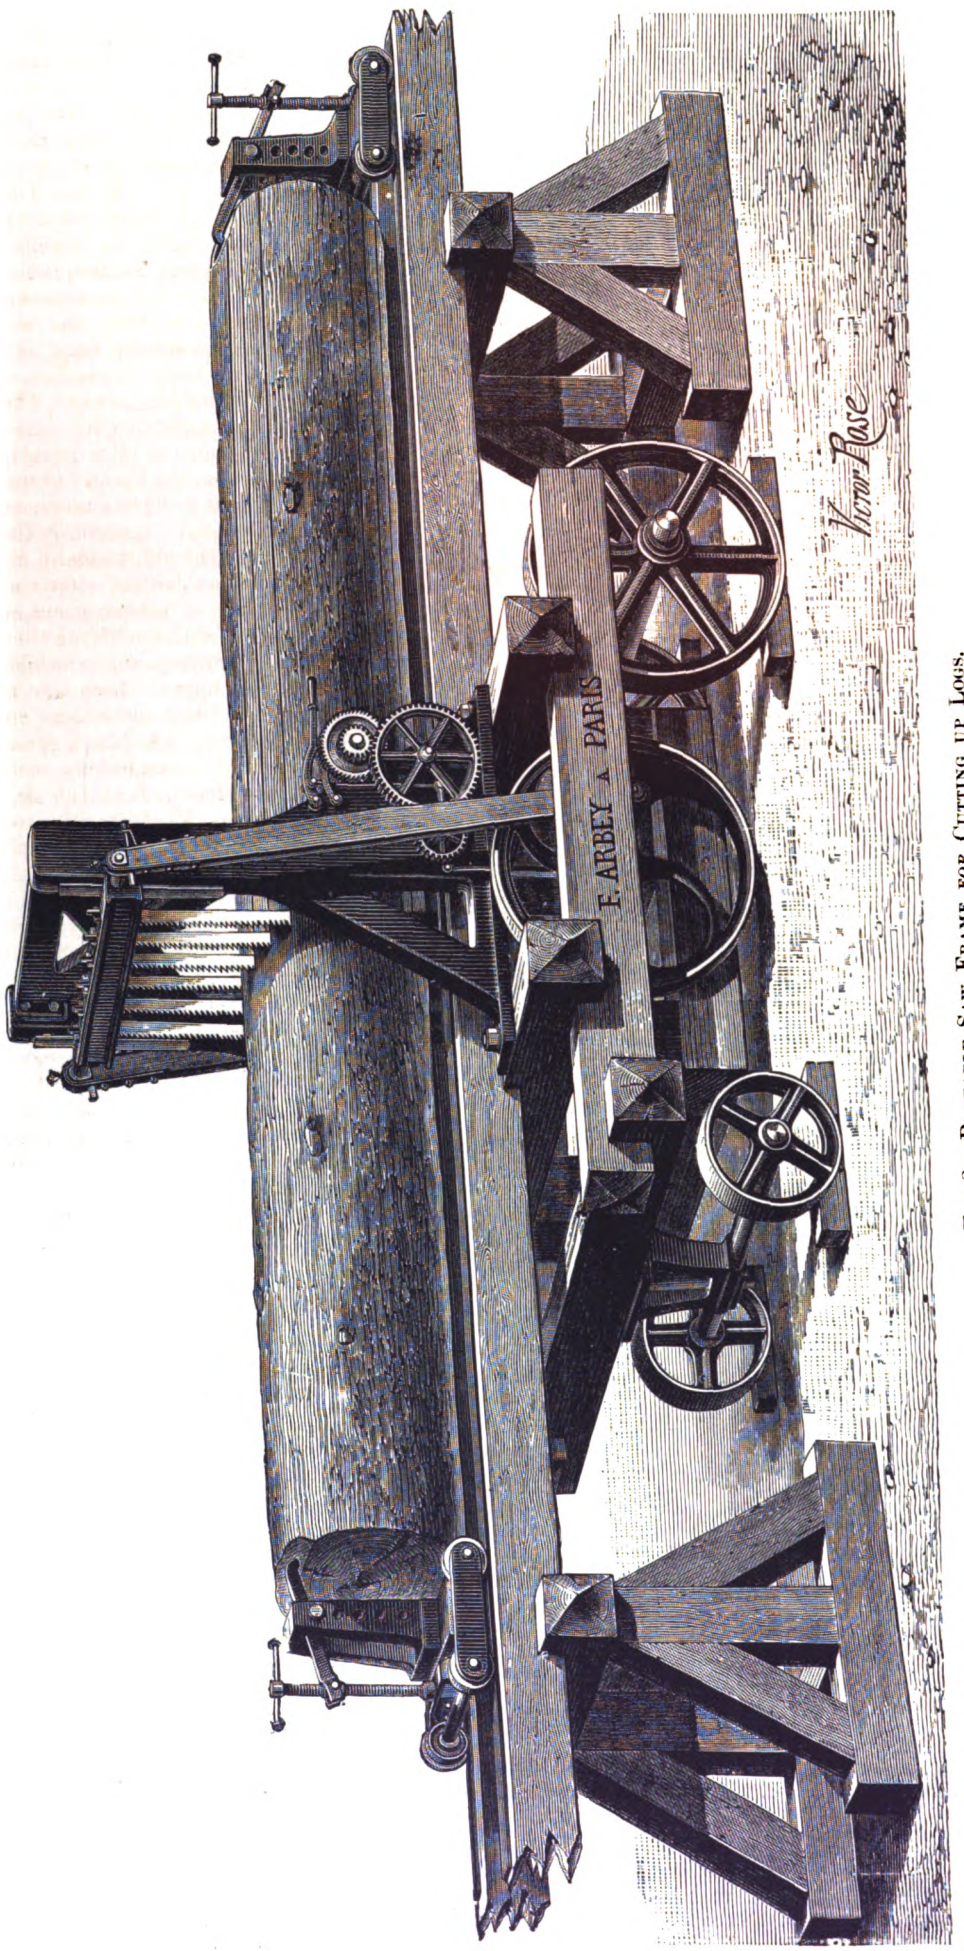
MESSRS. ARBEY'S TOOLS AT THE LATE PARIS EXHIBITION.

(For description see page 176.)



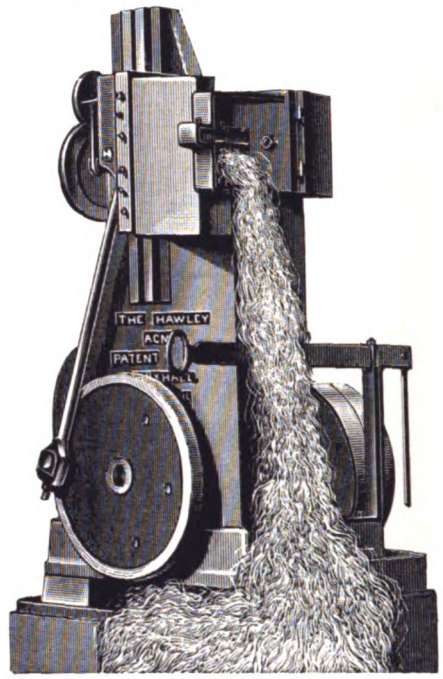


FIG. 2.—PORTABLE SAW FRAME FOR CUTTING UP LOGS.

MACHINE FOR MAKING WOOD WOOL.

MESSRS. JOSEPH M. WEBSTER, Derby Works, Carruthers Street, Vauxhall Road, Liverpool, are now placing on the market the Hawley "Acme" wood wool machine, which is illustrated below. The use of wood wool is coming rapidly into favour among manufacturers of glass cutlery, confectionery, &c., for packing purposes on account of its cleanliness and non-hygroscopic

properties, but its adoption is hindered, among other things, by its comparatively high price. The Hawley machine is intended to reduce the price, for it is of such a size and design that every manufacturer can have one working on his premises, and can thus turn out his own wood wool. Very little attention is required by the machine, and all the parts are easily renewable. Timber of any convenient length can be cut, and waste pieces can also be utilised.

THE NEW RULES FOR LIFE-SAVING APPLIANCES.

THE strictures which have been freely passed in certain shipping circles on the rules drawn out by the Board of Trade, based upon the "Merchant Shipping (Life-Saving Appliances) Act, 1888," are finding complete justification from the general attitude of shipowners and builders towards them, as well as from the fact of the Board of Trade having postponed the date on which the rules are to come into force. Messrs. Russell & Co., the well-known shipbuilders of Port Glasgow, wrote some little time ago to the local Board of Trade surveyors asking a few pertinent questions as to the precise bearing of the Act in a given case, to which they have received the polite but not very satisfying reply:—"For an explanation of the rules I am instructed to inform you that you should refer to the rules, and the local surveyor will see that they are carried out." Messrs. Russell & Co. are not the only firms, having at least ordinary business intelligence, who have been knocking at the door of the Board of Trade for enlightenment, only to be met with the polite request, "Refer to the rules"! Now the rules are, as we have already heard them characterised, a perfect "pigs-in-clover" puzzle. Readers honestly applying themselves to the task of comprehending their bearing in any given case are not long so engaged before they are compelled to give up in despair. The system of cross-reference adopted in framing the rules, while perhaps securing brevity, has imparted an element of confusion and uncertainty which might well have been avoided. The text of the measure has to be fished out piece-meal from amongst a plethora of "clauses," "divisions," and alphabetically distinguished paragraphs, until, after weary and painstaking efforts at tracking the full meaning from page to page and clause to clause, it, will-o'-the-wisp like, finally eludes the grasp. The operation of the Act has been postponed from the 31st of March to the 30th of June next. The Board of Trade could not exercise its latent energies to better purpose, between now and that date, than in modifying the present rules in *substance*, so as to more equitably meet the cases in which they at present bear so hardly, or at least in *form*, so as to be more intelligible to the reader, whose abilities find worthier scope than solving needless word-puzzles.

Advertisements intended for insertion in the current week's issue should reach our London Offices not later than first mail delivery on Thursday morning. Scale of charges for displayed advertisements on cover and inside pages will be forwarded on application. Orders for single advertisements must be accompanied by payment in order to ensure insertion, the charge for which is 2s. 6d. for the first four lines or under, and 1s. for each additional line. Situation advertisements (Vacant or Wanted) 1s. for two lines or under, and 6d. for each additional line—which averages eight words. While all practical regularity in the insertion of serial advertisements will be observed, it can only be absolutely guaranteed in the case of those ordered to appear weekly.

As we go to press early with certain of our advertisement pages, all Alterations to Standing Advertisements should reach the Publisher not later than 2 o'clock on Wednesday afternoon in each week.

All accounts are payable to GEO. CAWLEY, *358, Strand, London, W.C. Cheques should be crossed Manchester and Liverpool District Banking Co., Limited, 75, Cornhill, London, E.C. Post Office Orders should be made payable at the Post Office, 369, Strand, London, W.C.*

Industries:

FRIDAY, 21ST FEBRUARY, 1890.

THE PRESENT STANDARD OF LIGHT.

THE last quarterly report of Professor Williamson, the Chief Gas Examiner for the metropolitan area, brings to the notice of the London County Council many points of interest concerning the quality of the London gas during the last few months, and this again brings home to the guardians of the public the unsatisfactory nature of the present official methods for ensuring an adequate lighting of our large towns by the gas companies. At the present time, when electric lighting is making such rapid progress, the controlling authorities will soon have to adopt some method for ascertaining the illuminating power and efficiency of the lighting of the new rival to gas, and it cannot be too strongly urged upon those who have the interest of the public in their keeping to take steps towards introducing into Parliament a Bill which will deal with the question on such a broad basis that the competing systems shall be judged by a uniform and definite standard of light. For many years those engaged in the determination of the illuminating power of coal-gas have been unanimous in condemning the "Parliamentary candle" as unreliable at all times, and frequently official tests made with this standard are known to be worthless by the controlling authority, and yet, because the conditions as defined by law and the Gas Referees appointed by the Board of Trade have been complied with, the unoffending gas company is compelled to suffer the ignominy of a police-court prosecution and to pay the forfeiture laid down by law. Mr. Dibdin, the chemist to the London County Council, in a public discussion which followed the reading of a paper on the "Standards of Light," and while referring to the present mode of determining the illuminating power by candles in closed photometers, described the process as one which oftentimes necessitated the committal of "a nightly fraud" on the part of the gas examiners. Notwithstanding such a strong statement on the part of the scientific representative of the controlling authority, the late Board and the present County Council are still enforcing the present Acts. It is to be regretted that such lethargy in high places should thus retard progress in this direction, and we are not surprised that the Chief Gas Examiner, to whom all disputes between the gas company and the controlling authority are first brought, should express himself strongly on this subject. In a report on the appeals of the Gas Light and Coke Company against the official returns at two of the testing stations last year, Professor Williamson says: "The official system of photometry, like all such experimental operations, has been gradually undergoing improvement, but there is still one serious defect in it, namely, the standard of light. Sperm candles such as are ordered to be used by the gas examiners are officially known to differ from one another to the extent of at least ten per cent. of their illuminating power, so that one standard candle might show gas to have an illuminating power of 15·2, while another shows 16·8 as the illuminating power of the same gas." Still more recently the gas examiners have pointed out in a memorial to the County Council the same difficulty in the satisfactory working of the present Act of Parliament. They say: "It has long been recognised, and is now generally acknowledged, that of all standards of light, the standard at present adopted, namely, sperm candles, is the most unsatisfactory. So great are the discrepancies which may, and frequently do, arise from the use of this standard, that three successive tests of the same gas may vary by more than 1·5 candles, or 10 per cent., of the whole illuminating power. The Gas Referees themselves recognise that such a variation may arise from the inadequacy of the standard," and they proceed to urge that the County Council should take the necessary steps to have a more accurate unit of measurement adopted. Apparently the Gas Referees wish to adhere to the old standard, as they have not taken as a body any distinct steps towards altering the present system of measurement, but have contented themselves with modifying the style of photometer and the conditions under which the standard candles should be burnt. Last year we drew attention to some of these alterations (see *Industries*, Vol. VII., page 163), which as a general result have had the effect of considerably complicating the methods of procedure and at the same time afford the gas companies loopholes of escape if the gas examiners should depart from any of these refinements and directions in even an unimportant particular. The result of these so-called improvements on the method of manipulating candles has, however, been very unfortunate. For instance, those who are not under the London County Council, and who believe in the old standard, have now two standards to appeal to. The Gas Referees have, indeed, tried to remedy the evil, by prescribing an additional test to be taken after a further interval of one hour in those cases in which the return falls below the Parliamentary limit, but we should have thought that Professor Tyndall would have been able to persuade his two colleagues to refrain from insisting on such a useless expenditure of energy. We do not wish to urge the adoption of any particular fad or hobby, but when it is admitted by every photometrist that there are at least some half-dozen new standards which are undoubtedly superior to the "candle," the Gas Referees are not prescribing the mode to be adopted for testing in a satisfactory manner when they waste their time in patching up a system which is now acknowledged to be effete and exploded, instead of using their official position to advocate the adoption of a modern and better method. Professor Vernon Harcourt, as is well known, has in his individual capacity devised a new standard of light, and has shown, at the British Association and elsewhere, that it is capable of giving better and more trustworthy results than the candle. It would seem, therefore, that Professor Harcourt's colleagues either do not think highly of his Pentane standard or else are quite satisfied with the existing system. We hope the Board of Trade will ask the Gas Referees to furnish them with a report on their work, which will give them an opportunity of letting the public know their official views on this matter. We should not be surprised if a question should be asked in Parliament on this subject, in connection with the low returns of illuminating power which have been made by the official examiners at two of the testing stations of the South Metropolitan Gas Company during the recent period of strike among their employés. We hope that the subject will then be fully discussed, and that steps will be taken to amend the Act, so that the determination of illuminating power shall at last be placed on some approach to a satisfactory basis.

Electric lighting is developing so rapidly that electrical engineers will soon need a definite standard of light. Though the light of glowlamps is spoken of as so many candles, candles are never used in the determination. In London the Methven screen, or more recently the pentane standard, is employed. Electric lighting, being a new and interesting industry, has attracted the attention of a great many unpractical and purely scientific men; and they have brought out the square centimetre of solidifying platinum as a light unit. Gas companies and practical gas analysts have no leaning towards square centimetres or solidifying platinum, and such a proposal cannot but cause confusion. The British Association Committee has defined the candle in terms of the platinum standard; but unfortunately the matter, from a commercial and legal point of view, is none of the British Association's business. Whether the vague standard candle remains, or the definite pentane lamp comes into use, the practical standard will not be made to fit the platinum unit; but if the new standard does not come out the exact fraction of the platinum standard, it is the British Association unit that will have to alter, not the new standard. What is wanted is, not a definition of unit light that has the appearance of having something to do with the C.G.S. system, but a legally and accurately defined standard whose exact value can always be reproduced. In electric light work there is no definition of light, apart from the standard. A standard flame, if transparent, gives equal light in all directions; an incandescent carbon does not. What, then, is meant by the light of an incandescent lamp? The mean of the intensities in all directions should be taken. This last is a small matter, however, in comparison. What is wanted is that when a gas company has to supply sixteen-candle gas, and its profits depend on whether it gives sixteen-candle or fifteen-candle, the public should be able to claim sixteen-candle gas on the one hand and the company should not be obliged to supply seventeen-candle gas on the other. As we have already said, there is now no reason whatever why a company supplying proper gas should be reported by an analyst—who knows his results, though legally right, are actually wrong—and fined, merely because the authorities are too lethargic to adopt a standard which has been carefully prepared for them and laid ready to hand.

THE TEMPLETON MILL DISASTER.

The report of the Commissioners, Colonel Malcolm R.E., and Mr. W. W. Robertson, appointed by the Secretary for Scotland to inquire into the cause of the fall of Messrs. Templeton & Co.'s mill at Greenhead, Glasgow, a few months ago, has just been published, and, as it treats of matters of great interest to all engaged in large industries which require buildings of considerable height, a few of its chief points may be noted.

The Commissioners do not bring any serious charges against those who were connected with the construction, although they point out with great force, what struck us at the time the evidence was given, that there ought to have been more direct co-operation between the architect who designed the shell of the building and the engineers who were responsible for the arrangement of its interior and the constructions immediately depending on the machinery. In the case of the mill under consideration, there seems to have been no approach to collaboration, and all communications between the architect and the engineers were not direct, but passed almost entirely through Messrs. Templeton. The drawings were issued to the skilled workmen signed by the engineers, and there is some conflict of evidence as to how far they had been approved, or in some cases even seen, by the architect. These drawings gave details of the iron columns, beams, stanchions, &c.; and of course should all have been designed with reference not only to their special relation to the machinery, but also their more general relation to the walls and the structure generally. This matter, we think, brings out a weak point in the training of architects. They are taught to make a fine picture on paper, but questions of stability or strength are seldom considered. Every architect who takes up the department of mill work should be sufficient of an engineer, not only to design the walls, but to make out complete drawings from the sketches of the mill engineer, and the two should be jointly responsible for the plans.

The materials and workmanship of the buildings were of excellent quality, and the Commissioners are of opinion that no shortcoming in this respect can be held as having contributed to the accident. Neither do they think that the scaffold on the outside of the front wall, and the steam crane on the top tier of joisting, had anything at least directly to do with it. Even with the front wall, in which the architect departed from the original plans, they fail to find any fault, as they say that it exceeded the dimensions required by the Metropolitan Building Act, and, moreover, it was strongly supported by the joists.

The Commissioners differ from the opinions given by the witnesses as to the cause of the accident, and they find it in the back wall, which they consider the weakest part of the structure. Although this was not exposed directly to the force of the wind, it was subject to a large though unascertainable wind pressure, due to the openings in the front wall, and the absence of a roof, as well as to a considerable thrust transmitted from the front wall by the four tiers of joists which crossed the building. Against these forces the wall had nothing to oppose but its own lateral stability, which was not great, its thickness being less than that of the front wall, and somewhat under the requirements of the Metropolitan Building Act. Moreover, it was supported on lintels and stanchions, and had no connection, except at the two ends, with any other structure which could stiffen or support it. The Commissioners show that the wind, acting on this wall, would, by a series of gusts, not only play havoc with it, but also bring down the front wall. We need not enter into the details of their reasoning, but we may say that it seems sound, and at least gives one of the most probable causes of the accident.

The lessons to be learnt from the disaster are that it ought to be remembered that ordinary walls, when unsupported, have small lateral stability, and especially so when, instead of rising from solid foundations, they are carried on iron beams and columns, and that a building which may be strong enough and stable enough when completed, may require to have special precautions taken during its construction. In the present case some additional temporary strength should have been given both by transverse bracing of the building at intervals and by diagonal bracing of the floors. Moreover, the wall should have been thicker. Another lesson is that the engineer and the architect should co-operate in their work, and be jointly responsible for the plans, and that both should have a sufficient knowledge of each other's business to enable them to turn out a design which may be a harmonious unity, and not merely an architectural shell with a mechanical interior having little relation to the shell in the matter of construction.

THE CHAMBER OF SHIPPING.

The proceedings at the annual meeting of the Chamber of Shipping, which was held in London last week, showed that the association is in a vigorous condition; and it is certain, as was expressed by the retiring President, that the future of British shipping will, in a great measure, rest with the Chamber, if it remains united and strong, and the consciousness of this should ever be present in the minds of the members and give weight to the deliberations of the Chamber. Mr. Dunlop further said that the Chamber was likely to have, if it cared for it, an important part in the settlement of some of the questions that are agitating the wage-earning classes in this country and abroad, and he hoped that it would be instrumental in reconciling the differences between employers and employed as they affect shipping.

During the past year we have discussed more or less the various subjects which came before the Chamber, and, as they are likely to attract attention during the present year, we will only notice them very shortly at present. The question of light dues is still unsettled, and Sir Michael Hicks-Beach, who was present at the meeting, offered a Royal Commission for the investigation of the subject. Sir Michael also alluded to the Tonnage Measurement Act, and hoped that, whatever might be their feelings towards him in the earlier stages of the measure, they were not now absolutely hostile. The shipping interest had been so well able to take care of itself that various provisions had been inserted which had been of material advantage to that great industry. He alluded to the Maritime Conference which had been recently held at Washington, the results of which, he believed, would be of great importance to our mercantile marine. On the subject of collisions its discussions had been especially valuable, although he would have preferred that more definite conclusions had been come to on some matters, such, for instance, as an international load line. He was strongly of opinion that in all attempts at legislation the shipowners should be consulted, as he was sure that the great majority of them were anxious to do all in their power to safeguard the interests of the life and property committed to their charge.

Among the other subjects discussed by the Chamber were the penalties for smuggling, which fell heavily on shipowners, a compulsory load line, supply of seamen, and strikes. Mr. Edward Martin, on behalf of the Clyde Shipowners' Association, moved that the number of representatives from the various ports on the Committee of Lloyd's Register should be increased, and, notwithstanding the opposition of the Chairman of Lloyd's Committee, the motion was agreed to. It seems only right that this proposal should be carried out, and we trust that, when it has been conceded, those who are appointed will attend the meetings of the Committee, for it is said that at present the members who represent the outports are generally conspicuous by their absence. We intend during the year to note the points of the programme of the Chamber which come up for discussion in Parliament or otherwise, so that our readers may know what progress is being made.

A DISCOVERY OF COAL IN KENT.

For several years Sir Edward Watkin has been making experimental borings in the south of Kent for the purpose of discovering the beds of coal which his geological advisers tell him must exist there. The borings hitherto have proved fruitless, but Mr. Brady, the engineer-in-chief to the South Eastern-Railway, has now reported a successful issue of the experiments. His report says:—

"Coal was reached on Saturday last, the 15th inst., at 1,180ft. below the surface. It came up mixed with clay and reduced almost to powder by the boring tools. A small quantity of clean bright coal found in the clay was tested by burning and proved to be of good bituminous character. The seam was struck after passing through 20ft. of clays, grits, and blackish shales belonging to the coal measures, which at this point lie close under the lias, there being only a few intervening beds of sand, limestone, and black clay separating them. The correspondence of the deposits with those found in the Somersetshire coalfield is thus pretty close, the difference consisting in the absence of the red marl at the Shakespeare boring. The lines of bedding in the shale are distinctly horizontal. This is an indication that the coal measures will probably be found at a reasonable depth along the South-Eastern Railway to the westward. I beg to hand you herewith two specimens of the clay containing coal, one taken at 1,180ft. and the other at 1,182ft. I also enclose a specimen of clean coal taken to-day at 1,183ft. 6in. from the surface."

THE ROYAL METEOROLOGICAL SOCIETY.

The usual monthly meeting of this Society was held on Wednesday evening, the 19th inst., at the Institution of Civil Engineers. The first paper read was by the Hon. Ralph Abercromby, and entitled "Observations on the motion of dust, as illustrative of the circulation of the atmosphere, and of the development of certain cloud forms." The general conclusion was that, when the air is in more or less rapid motion from cyclone or other causes, small eddies of various kinds form themselves, and that they develop the different sorts of gusts, showers, squalls, and whirl-winds.

Then followed a paper on "Cloud Nomenclature," by Capt. D. Wilson-Barker. The author proposes a simple division of cloud forms under two heads—viz., Cumulus and Stratus—and recommends that a more elaborate and complete division should be made of these two types.

The last paper read was on "An Optical Feature of the Lightning Flash," by E. S. Bruce, M.A. It has been stated in the Report of the Thunderstorm Committee of the Royal Meteorological Society that there is not the slightest evidence in the photographs of lightning flashes of the angular zigzag or forked forms commonly seen in pictures. The author, however, believes that this is an optical reality, as the clouds on which the projection of the flash is cast are often of the cumulus type, which afford an angular surface.

Letters to the Editor.

THE MANCHESTER SHIP CANAL.

To the Editor of "Industries."

Sir,—Although I look on with a friendly eye at the progress now being made with the Manchester Ship Canal, still my mind is disturbed with some feelings of doubt.

The report of the Consultative Committee is pleasing, but the question, to my mind, is whether it is correct. Concerning the railway deviations, for example, it would be interesting to know how much of this work is actually done, and, at the average rate of progress for the last twelve months, how many years they will take to complete? With regard to the stone pitching of the bank, considered at the rate for the last six months, is it possible to complete this in ten years from the present date? Further, now that the expected supply of stone has failed, where is the stone to come from? Some very positive statements are being passed round on these points, and the statements are rather different to those given by the above-named Committee. The actual figures would please many besides the writer, who is one of the thousands interested in the scheme.

Yours, &c.,
Inquirer.

Warrington, February 18th, 1890.

WILLIAM MURDOCH.

To the Editor of "Industries."

Sir,—In reply to Mr. Alex. Murdoch's letter in your issue of the 31st January, several items of interest referring to Mr. Murdoch are to be found in the recently published autobiography of Richard Tangye. Mr. Tangye says "that it was at Redruth where Mr. Murdoch invented gas lighting and astonished the miners by carrying a lantern supplied by coal gas from a bladder which he carried under his arm. It was also at Redruth where he constructed the first locomotive made in England."

In 1889 Mr. Tangye and his brother had a granite slab placed in the wall of Murdoch's house, having the following inscription: "William Murdoch lived in this house 1782-1798; made the first locomotive here, and tested it in 1784; invented gas lighting and used it in this house 1792."

Yours, &c.,
C. J. W.

Manchester, February 19th, 1890.

SILICON IN IRON AND STEEL.

To the Editor of "Industries."

Sir,—In looking over the recent valuable contributions of Mr. Turner and others on the alloys of silicon and iron, it has occurred to me that a few remarks based on some years' experience in iron founding and steel casting may not be out of place, and may possibly prove interesting to some of your readers. For some time the silicon alloys of iron containing also carbon, and which may be termed the triple alloys of silicon, iron, and carbon," have been the subject of careful study, and have afforded a mine of information, of which practical founders and ironworkers have not been slow to avail themselves.

A proportion of the data given, and conclusions derived therefrom, may be said to be merely historical, long familiar to experts and specialists, but not as a rule to the average body of ironworkers, who in consequence paid little attention to the previous work of some metallurgists—prominently Mr. Riley—showing the marked influence of silicon on the physical properties of both steel and iron when alloyed with silicon. It, however, goes without saying that as regards the general results of recent investigations on silicon cast iron alloys, there can be no question that the methods of mixture, which previously were merely empirical, have been placed on a sound scientific basis; the ironfounder can now work with confidence, in accordance with specified reactions, and much that was before obscure, or even unexplained, has been rendered clear.

Briefly, silicon now ranks with carbon as a necessary constituent of both crude iron and steel, not as before, "according to generally received opinion," as an element to be avoided, but, on the contrary, to be used in accordance with certain known requirements and under well-understood conditions. It has been shown that silicon expels carbon from iron, thus rendering the metal grey or graphitic—or, in other words, carbon is less soluble in iron than silicon. The former is precipitated, and remains simply intermixed with iron. The graphitic carbon may be mechanically separated, as proved by Mr. Snelus.

It must not, however, be forgotten that temperature plays an important part in determining the greyness, or technically the No., of cast iron. A graphitic iron may be produced with a comparatively low percentage of silicon by slow cooling. Thus, a very grey pig iron may be produced from the same materials, and without altering the furnace burthen, which, if quickly cooled, would be little better than common grey forged pig iron. So marked are the results of cooling, that even in the same pig bed several varieties of grey iron may be obtained, and to obtain a good graphitic pig slow uniform cooling must be practised and quenching with water avoided. The initial temperature of casting and subsequent cooling are factors which should be considered, but which recent investigators appear to have rather ignored, very possibly deeming that the new method, based on the relative solubility of silicon and carbon in iron, stood on its own merits, regarding the older well-known methods of slow cooling, &c., as being outside the limit of their investigations.

It is, however, submitted that the initial temperature of casting and the subsequent rate of cooling must of necessity play a part in the final results, whatever may be the percentage of silicon. It may therefore be premature to say that a sufficient percentage of silicon only suffices for the formation of graphitic iron, and that the rate of cooling, &c., is unimportant. Molten metal slowly cooled—or, in other words, solidified—rejects, like water when frozen, foreign substances previously held in solution. A relative rejection, corresponding to the rate of cooling and the relative solubility of the various elements presumably held in solution in the fluid state, may occur. Graphite may be mechanically separated from iron, and it is certainly curious that the mere presence of a body simply intermixed with iron should modify its physical properties, as it undoubtedly does.

Dr. Percy states that the simple intermixture of a foreign body with a metal may not always influence its malleability, and states that the malleability of an ingot of copper was not affected although it contained 22 per cent. of tungsten, the whole of which, he was certain, was present in a state of mechanical suspension. It is difficult to understand how the presence of such a large quantity of merely intermixed tungsten did not affect the malleability of the ingot; sensible particles of copper must thus have been kept apart from each other, and in consequence malleability or coherence of the pure metal deteriorated.

We, however, know that suitable bodies may be mechanically intermixed, which when afterwards subjected to heat or pressure, or even left to themselves, adhere closely together. Instances are so numerous and simple that quotation is scarcely needed. These may, however, be roughly divided into two groups—viz., (1) those in which a body of high fusion point is mixed with another fusing at a lower temperature: the mere application of a heat roughly corresponding to the latter must, it is evident, bind both together, forming on cooling a solid coherent mass of some strength, and which whilst hot might even be malleable; (2) intermixed bodies in which under proper conditions *quasi* chemical combination takes place.

May we assume that in degree the same reasoning may be applicable to iron? It is known that certain elements, when present in iron, modify its properties; can we go further and regard crude iron—(1) as an intimate mixture of two or more bodies, or (2) bodies in *quasi* chemical combination, which, under certain conditions, may be suitable for a given purpose, but which, under others, may not. Something may be gained by regarding iron as a mechanical mixture of one or more bodies? It does not, however, follow that recognised chemical combinations with iron do not play a part; these should not be ignored, but regarded as affording additional aid in explaining certain phenomena of everyday occurrence in the iron manufacture, and which certainly have not as yet been satisfactorily explained.

In rolling wrought iron bars a better weld is obtained when the mass or pile is well intermixed with a fluid cinder or slag. This has been explained as being due to the protection of the iron from superficial oxidation by the slag. Thus clean surfaces of iron are brought in contact, and therefore perfectly welded together.

But the theory does not always account for the behaviour of certain qualities of iron under similar conditions; for instance (even with considerable care and with the aid of slag), steel and wrought iron cannot well be welded together, but the interposition of a moderately thin plate of a softer or intermediate quality of steel greatly facilitates the welding together of the total mass. Here we have an instance of an intermediate body assisting the union of iron of dissimilar chemical composition, one containing little or no carbon, the other a steel containing as much as half per cent. carbon, and even sometimes more, and of different fusion point. Further, we may have any number of thin plates, or even particles of varying composition, symmetrically arranged forming, on being heated and rolled, a coherent mass of metal.

According to Professor Akerman, mechanical work, and especially hardening in the usual manner, causes a more intimate union between carbon and iron, which union may be relaxed in a greater or less degree by reheating and subsequently slowly cooling. Professor Akerman also deems it probable that carbon is present in iron in three forms—viz., first, as carbon in combination; second, graphite; and lastly, in the intermediate condition, changing from combined carbon to graphite, or *vice versa*; thus furnishing a key to the changes which iron may undergo under varied conditions of heating, cooling, and mechanical work. Granting this, have we not here a clear instance of either a mechanical mixture of iron and carbon or what may be termed *quasi* chemical combination, and it seems probable that this intermediate or cement condition of carbon determines the adhesive power of the unit molecular mass, and therefore its physical properties, ductility, tensile strength, &c., in accordance with variations in heating, cooling, and mechanical work.

It is not, however, certain that this intermediate condition of carbon is always present in iron; indeed it has been asserted that carbon cannot be said to exist in this form at all. On the whole it is probable that the above suggestions are of little use except as affording material for further investigation and discussion.

Mr. R. Hadfield, going a step further, has endeavoured to form alloys of iron and silicon only, rightly assuming that the physical properties imparted to iron by silicon alone were masked in the presence of a sensible quantity of carbon. He does not appear to have succeeded in producing a pure alloy of iron and silicon, but by using a pig iron high in silicon and correspondingly low in carbon—"ferro-silicon"—he has, however, succeeded in producing what, "in contradistinction to a carbon," may be termed a silicon steel. This alloy is not, in his opinion, equal to ordinary carbon steel. Silicon cannot take the place of carbon; the latter has always the advantage of being more easily applied and of producing a material more suited to the requirements of the steel worker. It is proved that silicon, unlike carbon, does not confer on iron the properties of becoming hardened when water-quenched. The writer, however, does not consider that Mr. Hadfield has, "strictly speaking," produced a pure silicon steel.

According to the analyses given, the samples contain carbon from ·25 per cent. down to ·01, the latter containing 7·23 silicon. Such percentages of carbon as ·14 per cent. or ·18 per cent., with respectively ·24 and ·79 per cent. silicon, are quantities of carbon quite likely to modify the properties of silicon steel; quantities of carbon equal to $\frac{1}{10}$ or even less modify the quality of steel, and steel containing ·14 per cent. carbon is materially softer than an ·18 per cent. carbon steel of ordinary make with traces of silicon.

The non-hardening of silicon steel by water-quenching can hardly be termed a disadvantage; for certain purposes it is evident that a material not susceptible to changes would undoubtedly be useful. It is suggested that we have yet to learn what would be the properties of silicon steel with carbon reduced to the level of a technical impurity such as sulphur or phosphorus—*e.g.*, a silicon steel with, say, not more than ·05 carbon, preferably less, and about a quarter per cent. silicon—or a metal in which practically silicon altogether replaces carbon. Steel manufacturers are quite cognisant of the fact that ordinary rail steel, or even the softer varieties, containing a notable proportion of silicon, can be easily rolled or otherwise manipulated. The writer can quote many instances in which a steel containing ·25 per cent. and even more of silicon worked even better than the ordinary metal, but, as a rule, yielding a brittle hard steel. Rails, however, containing silicon have been approved; further, rails with 1-10th per cent. silicon, even up to 2-10ths, have been demanded as being superior to ordinary rail steel. It may indeed be said, it is probable, that good steel is never quite free from silicon, and some metallurgists assert that no steel can be said to be absolutely free from this element.

In some localities, however, the presence of any appreciable quantity of silicon seems inadmissible, the chemical composition as regards carbon, &c., corresponding to that of other makers and differing only as regards silicon. No reason can be assigned for the discrepancy; yet in the writer's experience this has repeatedly occurred; it may, however, be due to unnoticed modifications in casting, heating, and rolling. On the whole, it seems to have been fairly well established that good rail steels always contain at least distinct traces of silicon, and that up to a certain limit of silicon, not as yet strictly defined or known, improved results are obtained.

As an instance of how long-standing ideas may be modified, or even altogether discarded, we may take the positive assertion that the silicon in ordinary spiegeleisen should not exceed 1 per cent., and that spiegel containing more could not be used without deteriorating the quality of the steel. Now, the writer, many years ago, under pressure of circumstances, and much against his will, was compelled to use spiegel containing, to him, the fatal quantity of 3 per cent. silicon. The resultant steel worked well and bore the usual tests; analysis gave the usual amount of silicon—viz., from ·02 to ·04 per cent. It was, however, noted that on pouring the silicious spiegel into the blown metal the white flame shooting out from the converter—due to the reaction of carbon on the dissolved oxygen (or, query oxide of iron) in the blown metal—was very feeble; the metal also did not boil to the same extent. At the time it was inferred that silicon was *preferentially* oxidised, thus saving carbon, and henceforth a moderate quantity of silicon in spiegel was not objected to. On another occasion only about half the usual quantity of spiegel could be obtained for the cast, and the weight was made up by adding No. 1 grey hematite pig iron. The steel worked as usual, and was considered even better than some casts of steel made the same day in the ordinary manner. I need not say all these reactions have since been worked out, and therefore need no further comment here.

Yours, &c.,
Metallurgist.

South Wales, 19th February, 1890.

THE INSTITUTION OF CIVIL ENGINEERS.

At the twelfth ordinary meeting of the Session, on Tuesday, the 18th inst., the President, Sir John Coode, K.C.M.G., being in the chair, three papers were read on Water Works in China and Japan.

I. The Shanghai Water Works, by Mr. J. W. Hart, M.Inst.C.E.

The Shanghai Water Works were the first water works constructed either in China or in Japan. The city of Shanghai, the chief commercial centre of North China, consisted of foreign settlements and a native city, the population of the former, English, American, and French, being 170,000 in 1885, and of the latter, by estimation, from 100,000 to 150,000. It was situated on the west side of the River Hwang-Poo; the country was flat and of alluvial formation. The necessity for an efficient water service had been recognised for twenty years previous to 1880, when the author was invited to investigate the question again, and to prepare plans and estimates, which were accepted; and a concession was granted by the municipality to construct the works. To secure a constant supply of water the author constructed, in a central position, within the English settlement, a water tower, to contain a reserve of 150,000 gallons at an elevation of 103½ft. above the main. To obtain a foundation on the unstable water-logged soil, the author discarded the use of piles, and, after trial experiments, particulars of which were given, adopted a concrete foundation 5ft. thick, and founded upon 2½ft. of rough rubble, the area being 68½ft. by 65ft., and the total weight to be supported 3,725 tons, or 1,847lb. per square foot, being only a little more than 51·25 per cent. of the load applied in testing the ground. When the work was completed, it was found that the steady, accumulative weight of materials used (2,735 tons) had caused an even settlement of 2½in. The superstructure for supporting the tank was exclusively of iron, octagonal in form, 52½ft. in diameter. The tank was 50ft. in diameter by 12¼ft. deep, and contained 670 tons of water. The roof, covered with corrugated galvanised iron, closely resembled the construction of an umbrella when open. The centre tube was 6ft. in diameter and 82½ft. long. One 20in. pumping main had been laid between the water tower and the pumping-station 3 miles lower down the river, and provision had been made for a duplicate main. The mains were connected with the tower by a breeches-pipe communicating with the centre tube. The arrangements for the admission and egress of the water by valves were described. The water left the tower through meters, and was registered every day at noon, and the quantity compared with that

Digitized by Google

delivered from the pumping station. In front of the water tower, a 20in. by-pass main connected the inlet and outlet branches of the pumping and service mains, so that the water could be delivered direct through the settlements. When the tank had been filled with water the total subsidence of the foundation was found to be 2½in. The total cost of the water-tower, exclusive of land, was £11,849. The Yang-Tsze-Poo works and pumping station were on the banks of the river Hwang-Poo, below the shipping and harbour limits, but within the area of the Anglo-American settlements. The site had the advantage of being down the river, below the native city, foreign settlements, and shipping, and at the intake-well the risk of contamination of the water from these sources and from the creeks was avoided. The sewage from the settlements and native city, and the impurities from the shipping and from the creeks, were carried into the upper reaches of the river by the flood-tide. The valves of the intake-well were so placed that when opened they could not admit water until one hour after the flood-tide had set in; therefore the water entered the settling-reservoirs nearly at the top of flood-tide, when it was in its purest state; but the river was always in a turbid condition. There were two settling-reservoirs, with an exposed water surface of 75,000 square feet, collectively; each reservoir was 250ft. by 150ft. by 13½ft. deep, with a total capacity of 6,130,312 gallons. The walls were constructed of concrete on the foreshore of the river, in one continuous slab for the entire circumference. The intake-well was a cast iron cylinder 6ft. in diameter, and was placed in the river 25ft. beyond low-water mark. The inlet valves were bolted inside the cylinder, and had strainers outside; they were 2ft. above low-water mark. The total cost of the settling-reservoirs (exclusive of the cost of land) was £11,058, being £1,804 per million gallons capacity. The service-tank for feeding the filter-beds was 220ft. by 92ft. by 8½ft. deep, and contained 996,000 gallons of water. The walls were of brick; the floor was of concrete 12in. thick, laid on 12in. of rough rubble. The tank was divided into three compartments, communicating by equalising-valves, so that the sediment could be flushed out of any one compartment while the others were in use. There were four filter-beds at present, having a total surface of 4,266·5 square yards, and each bed was designed to filter 30,000 gallons of water per hour. They were all 120ft. by 80ft. by 9½ft. with 5½ft. of filtering materials. The floors were of concrete 12in. thick, laid on 12in. of rubble. The only particular in which the construction of the beds differed from the ordinary plan was the application of a special supply valve for feeding the filters with water, so as to ensure a uniform head, which might be varied at pleasure. The average rate of percolation had been 540 gallons of water per square yard per twenty-fours hour, and the average duty of each filter 9,000,000 gallons before it required cleaning. The clear-water covered service-reservoir had a capacity of 840,000 gallons. It was 120ft. by 80ft. by 14ft. deep. Provision was made for diverting the water from the filter to the main pumping well direct, and for shutting off the reservoir should it become necessary to do so. The main building was 180ft. long, 61ft. wide, and 20ft. high; it contained the engine-house, valve- and gauge-room, and an office. Under the same roof were the boiler-house, stores, and workshop. In consequence of the faulty character of the ground, the chimney for the main boilers, which was 103ft. high, was built on a foundation block of concrete 20ft. by 50ft. by 4ft. thick. The total weight on the foundation was 571 tons, equal to 3,201·5lb. per square foot. There were two sets of horizontal compound pumping engines, each designed to deliver into the water tower 75,000 gallons per hour; and two sets of duplicate centrifugal pumping engines raised the water from the settling-reservoirs to the high-level service tank. There was also, within a few feet of the settling-reservoirs, another independent engine and boiler-house for a second set of centrifugal pumping engines. Here there was a deposit well and steam engine for facilitating the clearing of the settling-reservoirs of sediment. The cost of the Yang-Tsze-Poo pumping station, inclusive of culverts, by-passes, and valve wells, but exclusive of the cost of land, had been: Service tank, £1,913, or £192 1s. 6d. per 1,000 gallons capacity; filter-beds, £6,056, or £1 8s. 5d. per square yard of area; service reservoir, £2,938, or £349 15s. per 1,000 gallons capacity; main building, £2,567; and chimney for boilers, £798. Sluice valves were placed on the pumping main between the Yang-Tsze-Poo Works and the water tower, at an average distance of 500 yards apart. The mains extended to all the roads and streets in the settlements and suburbs: their size varied from 18in. in diameter, on leaving the town, to 5in. in the public roads and streets; in passages, courtyards, and alleys, the largest size was 3in. in diameter, and the smallest 1½in.; aqueduct mains were 20½in. in diameter. Four hundred and fifty hydrant posts were placed in the roads and streets, and there were numerous private fire-valves. All house fittings were supplied and laid by the company. Tin-lined lead service piping for domestic supply, was the only class used. None but screw-down draw-traps were allowed, and every service pipe was provided with a stop-valve immediately inside the building it supplied, while another was placed in the street, at the boundary of the consumer's property, and was under the control of the waterworks company only. Duplicate 12in. meters recorded all the water passing into the French settlement. The water supplied to the American settlement was registered by a set of 8in. duplicate meters; and there was a similar set at the boundary of the English settlement, where the main crossed the Defence Creek for supplying the suburbs. All the main pipes, service pipes, and sluice valves were coated with Dr. A. Smith's preservative solution, applied at a temperature of 600° Fahr. The cost of laying the pumping and the distributing mains, inclusive of all charges, per pipe of 12ft., varied from 19s. for a main 20in. in diameter to 7s. for a pipe of 5in. diameter. The total length of mains and service pipes was nearly 39 miles, and their weight 5,460 tons. One advantage of the water works was the great reduction in fire insurance premiums, the direct aggregate annual saving to merchants and property owners being not less than £90,000 to £100,000. Formerly a limited supply of filtered water was delivered in carts to the houses of customers by a small local company, at rates varying from 6s. 6d. to 13s. per 1,000 gallons; whereas, from the date of starting to December, 1887, the company's receipts for 2,447 million gallons of water, delivered to the community on the constant service system, were at an average rate of 5·7d. per 1,000 gallons. The Shanghai Water Works Company was registered with a capital of £100,000, subsequently increased to £120,000, and a further augmentation to £145,000 would be necessary. This expenditure would amount to 17s. per head, exclusive of the native city and of the population afloat. The works were commenced in August, 1881, and were inaugurated for public service in July, 1883.

II.—The Tytam Water Works, Hong-Kong, by Mr. Jas. Orange, Assoc.M.Inst.C.E.

The works described in this paper were originally projected in 1873 by Mr. J. M. Price, the Surveyor-General of the Colony, but actual operations were not commenced until the beginning of 1883. The works were divided under four headings, namely, the formation of a storage reservoir at Tytam, by the construction of a concrete dam, together with by-wash, &c.; the boring and completing a conduit tunnel through the Tytam range of hills; the construction of a masonry conduit; and the construction of filter-beds and a service-reservoir. The storage reservoir was situated in the Tytam valley, five miles from the city of Victoria; the height of the surface of the water above the sea was about 500ft., the drainage area was about 700 acres, and the area of the reservoir 27 acres, which latter contained about 310 million gallons. The dam was constructed of Portland cement concrete, of different proportions. There was an inner and an outer facing of granite, and the mass of the dam had granite stones embedded in the concrete, the water-tightness of the work depending upon the thin skin of rich cement concrete next to the inner face. A valve well, with five inlets into the reservoir, was constructed, and was divided into wet and dry compartments by a cast iron midfeather, so that the valves, &c., were easily examined. A scour pipe was fixed at the bottom of the dam communicating with the reservoir. The dam was 120ft. high, and contained about 66,000 cubic yards of materials. The by-wash was built away from the dam, and led to a separate valley; it had 100ft. clear waterway, over which a road bridge was built. The greatest observed depth of water over the by-wash had been 4ft. The total cost of the reservoir works was about £99,000. The water was conveyed to the tunnel inlet by cast iron pipes. The tunnel was 2,428 yards long, and about 7ft. 6in. square. Almost the entire length was through very close and hard granite. The boring was effected by 3in. machine drills, actuated by compressed air; the explosive principally used being dynamite. The work, after a preliminary training by European miners, was carried out entirely by Chinese labour, and occupied four years. A description was given of the method of alignment, which proved successful, the two headings meeting to ⅛ of an inch, while the difference of level was 0·08ft. Inlets and outlets were built at the respective ends of the tunnel, and were in finely worked granite with a considerable amount of details in the mouldings, &c. The cost of boring the tunnel was £48,269, equal to £19 17s. 7d. per lineal yard. The outside works raised the total cost to £53,950. About 62,000lb. of dynamite, 16,000 coils of fuse, and 5,400 tons of coal were used. From the tunnel outlet the water passed to the conduit, which wound, for a distance of over three miles along the mountain sides, to the site of the service-reservoir above the town of Victoria. The conduit was 3ft. wide and 2ft. 6in. high, and was built with a concrete bottom, brick sides, and granite cover stones, the sides and bottom being rendered with cement. Owing to the numerous ravines and gullies, there were about 100 bridges and culverts. The principal works were aqueducts of twenty-one spans of 20ft. arches, and double or 36ft. spans; there was also one heavy cutting through a hill spur 95ft. in depth. A small service-reservoir, containing about a million and a half gallons, was constructed midway of the conduit length. The principal quantities of work were about 30,000 cubic yards of excavation, 15,000 cubic yards of masonry and walling, and 1,200 cubic yards of concrete, the total cost being £34,700. The conduit delivered the water to the filter-beds and service-reservoir. The site for these latter works was extremely irregular. The filter-beds were constructed half in cutting and half by wall and bank, the cutting being 60ft. deep, and the wall up to 24ft. in height. There were six beds, each bed averaging 541 square yards. The filtering material was gravel and sea-sand washed. The service-reservoir, which contained about six million gallons of water, was constructed across a ravine, three sides being in cutting, and one side a wall and bank 62ft. in height; the depth of the reservoir was 30ft. The stream was taken under the reservoir in a culvert 16ft. wide. All the walls were made of local lime concrete, a facing of stone being used for the sides of the walls exposed. The principal quantities of this work were about 96,000 cubic yards of excavation, 11,000 cubic yards of walling and stonework, and 16,000 cubic yards of concrete; the cost was £22,761. The total cost of the works described was £209,579, taking an assumed value of the Mexican dollar of 3s. 4d. All local payments were in dollars. The consulting engineer for the reservoir and tunnel works was Sir Robert Rawlinson, K.C.B., Vice-President Inst.C.E.; the engineer-in-chief was the Surveyor-General of the Colony, Mr. John Macneil Price; and the author was resident engineer, and prepared the designs for the conduit, filter-beds, and service-reservoir, and all the working drawings.

III.—The Construction of the Yokohama Water Works, by Mr. J. H. T. Turner, B.Sc., Assoc.M.Inst.C.E.

The works for the water supply of Yokohama were completed in October, 1887. This was the first undertaking of the kind in Japan. Its inception was largely due to the recognition by the Japanese Government of the close relation subsisting between the use of polluted water and the development of choleraic epidemics at Yokohama. The principal original features of the works were that they were constructed in a country subject to earthquakes, and to meet the peculiar requirements of a Japanese population. The source of supply was the River Sagami, which was tapped at a point about 28 miles distant from Yokohama. The water was raised from the river by steam-pumps, and was delivered into a depositing tank built on the mountain side. It passed from this tank through a gauge-plate into the aqueduct, and flowed by gravitation to the town. The upper portion of the aqueduct was composed of alternate lengths of 18in. cast iron main pipe and masonry conduit, constructed along the precipitous rock wall of the Sagami cañon. The hydraulic gradient of the first 18 miles of the aqueduct was 6ft. per mile, and of the last 9 miles, 14ft. per mile, the diameter of the main-pipe being reduced to 15½in. Lead joints were employed everywhere except at the river crossings, where flange joints were adopted. The main-pipe delivered the water to the filter-beds and service-reservoir, which were situated at Yokohama, about one mile from the centre of the town. The filter-beds were three in number, two being ordinarily in use together; they were built of concrete. The filtering material consisted, essentially of a depth of 2ft. 6in. of sharp sand, supported in the usual way upon gravel, and underlaid by brick drains. The service-reservoir was a concrete structure, the walls being faced with brickwork. The depth of water was 18ft. Both the reservoir and the filter-beds, and all wells and tanks, were built upon, and entirely surrounded by, good puddle up to the water-line—a feature of construction to which the water-tightness of all these structures was doubtless largely due, and which might be regarded as almost essential in earthquake countries. A system of by-passes permitted of the water being delivered direct to the town, without passing through either the reservoir or the filter-beds, if it was necessary to do so at any time. The distribution in the town was effected by a ramification of 4in. and 8in. pipes branching off an 18in. main pipe from the service-reservoir. The service was constant. Stand-pipes were largely used for the supply of the native portion of the town, and lead service pipes were introduced into the houses of the foreign settlement. Fire hydrants were provided in large numbers throughout the town. The entire town was placed under the control of the waste-water meter system for preventing waste of water. Water was sold by measure to manufactories and shipping, the town being rated for all domestic supply.

BRICK PRESSING MACHINE.

Mr. William Johnson, Castleton Foundry, Armley Road, Leeds, has lately brought out a special machine for pressing sand-faced bricks. After the bricks have been formed in any ordinary way they are rolled in sand and placed in the special machine referred to and illustrated herewith. Five moulds are fitted on a table, which is given an intermittent revolving motion by means of a pawl and ratchet disc. The sides of the moulds are hinged at the bottom, and they are caused to swing round these hinges by runners and inclined planes. In this way the moulds are opened for the reception of the brick and closed to grip it for pressing. The moulds are open when the table is stationary, and during this time the bricks are placed within them. The table then moves on, and brings one of the moulds and its bricks into position under a vertical presser which is worked by steam power. After this operation the mould passes on, and is opened again to allow the brick to be taken out. The result is that the sand is pressed evenly all over the surface of the brick.

BOULT'S "TRICORD" LIGHT ADJUSTER.

The accompanying illustrations—Figs. 1 and 2—show an ingenious arrangement for adjusting a light, which has been designed by Mr. W. S. Boult, Assoc.M.Inst.C.E., of Liverpool, and which can be used with advantage for many purposes, for the light can be tilted to any position, and still be self-supporting. A small brass boss, with three radial arms, is screwed on to an ordinary lamp-

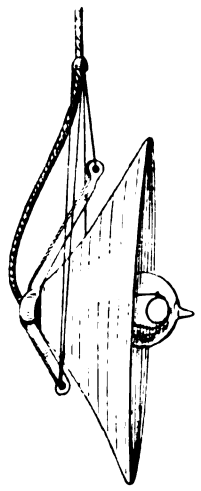

Fig. 1.

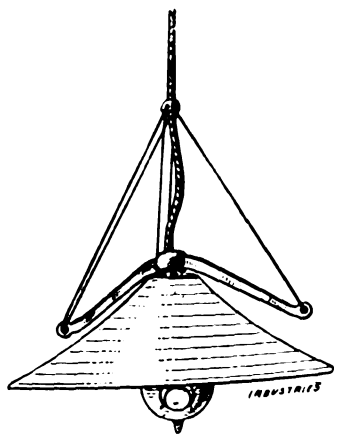

Fig. 2.

holder, and takes the place of the usual cord-grip; a little brass basin-shaped block is supported in a convenient position on the hanging conducting wires by an internal india-rubber washer, the block and radiating arms being connected by an endless silk cord. The cords and arms adjust themselves to the different positions accurately, and the whole arrangement is very neat and effective.

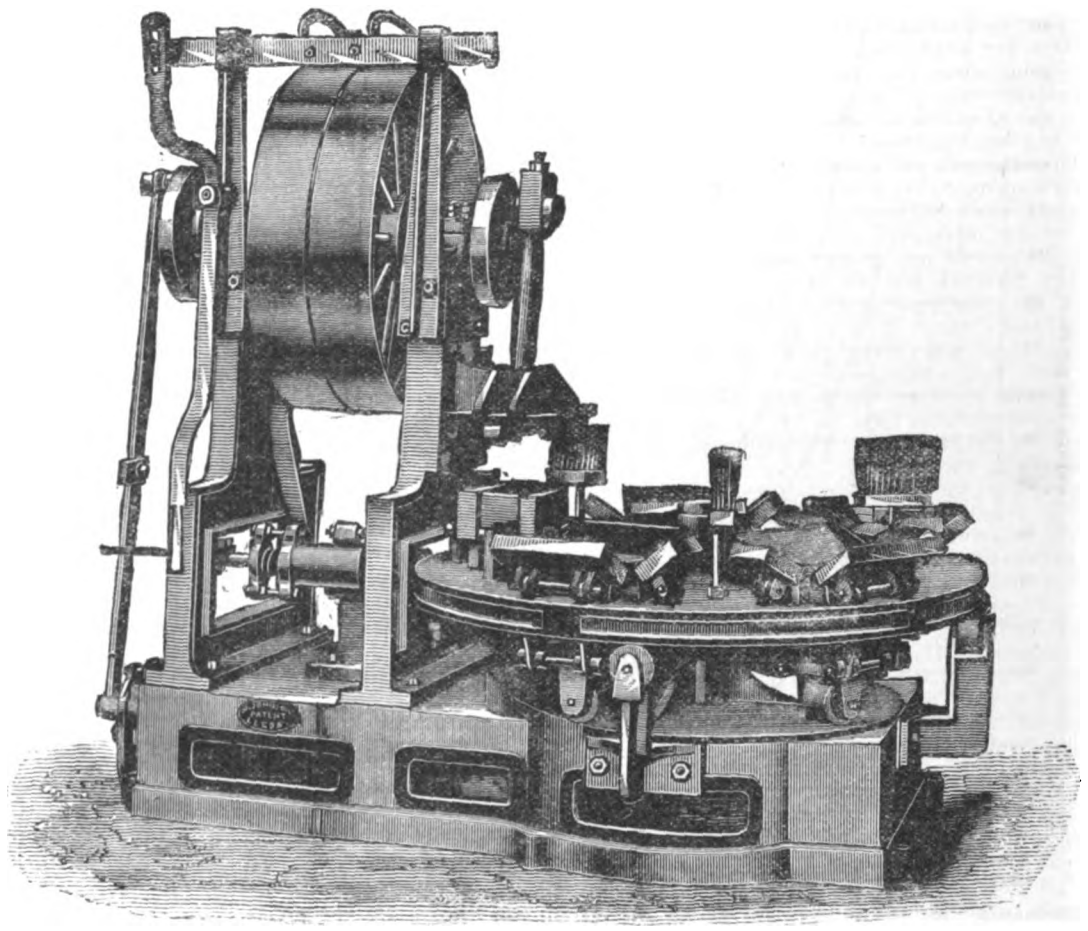
THE PHYSICS OF ELECTRIC LAMPS.

On Friday evening last Dr. J. A. Fleming gave a lecture at the Royal Institution on "The Physics of Electric Lamps," of which we give a short summary as follows:—

In an incandescent lamp the carbon filament, which is enclosed in a very perfect vacuum, will only stand a certain amount of current being passed through it, the limiting current being represented by the expenditure of 360 foot-pounds per second per square inch of cross section, or by a temperature in the filament equal to the melting point of platinum. After this current and temperature have been exceeded, the filament disintegrates, and carbon molecules are gradually dislodged and become deposited on the sides of the surrounding glass globe. The theory is that these carbon molecules are shot off in straight lines, and carry with them a negative electrostatic charge whose potential is equal to that of the negative electrode of the filament.

The reason for supposing that the particles are shot off in straight lines is two-fold. In the first place it has been noticed that when one particular point of the loop of the carbon filament has had too high a resistance, owing to faulty construction, the resulting spray of carbon molecules has been projected all over the interior of the glass globe, with the exception of one narrow space. This space has been found to be, as it were, the shadow on the globe of the perfect limb of the filament, with respect to the faulty point of high resistance in the other limb. It would thus appear that the perfect limb stood in the way of a spray of molecules which moved in straight lines.

Another reason for supposing that the molecules are projected in straight lines may be deduced from the phenomenon known as the "Edison effect." This phenomenon is obtained by interposing a metal plate or other conductor between the two limbs of the filament, and not in connection with either, and by raising the strength of current to the limit mentioned above. It will then be found, by testing with a galvanometer, that the potential of the metal plate is equal to that of the negative electrode. This effect is explained by supposing that the carbon molecules leaving the filament are charged with negative electricity, and, striking against the metal plate, raise it to a potential equal to that of the negative electrode. If a non-conducting shield is interposed between the negative loop of the filament and the metal plate, no such effect is observed, nor is there any such effect if the metal plate is arranged in such a way that the path between the filament and the plate is not a straight line. Therefore it is probable that the carbon molecules are projected in straight lines from the negative loop, and are charged with negative electricity.



Then comes the consideration as to how the molecules obtain their negative charge. When the molecules are dislodged they become inductively charged by the electrostatic field, and their positive electricity becomes discharged at once by the red hot carbon, according to Guthrie's well-known principle. It also follows from these experiments that the potential in the greater part of the filament is equal to that of the negative electrode.

Dr. Fleming then proceeded to discuss the similar phenomena in an arc lamp. By feeling about with a thin pointed conductor through the space between the two carbon poles, it has been discovered that the potential of the arc is for the greater part of its length equal to that of the negative carbon, and that the rise of potential is very sudden at a point extremely close to the positive carbon. It is also known that carbon molecules are projected from the negative limb, and it is supposed that the spray thus formed, acting in a similar manner to that of a sand blast, produces the hollow crater in the positive carbon. The temperature of the arc is greatest just in the hollow crater of the positive carbon, and this may be due to the bombardment of the projected carbon molecules.

Dr. Fleming also mentioned that his assistant, Mr. Bate, had discovered that the "Edison effect" could be obtained in the ordinary atmosphere as well as in a vacuum, although in that case the effect was only instantaneous owing to the carbon filament being so soon destroyed.

BRICK PRESSING MACHINE.

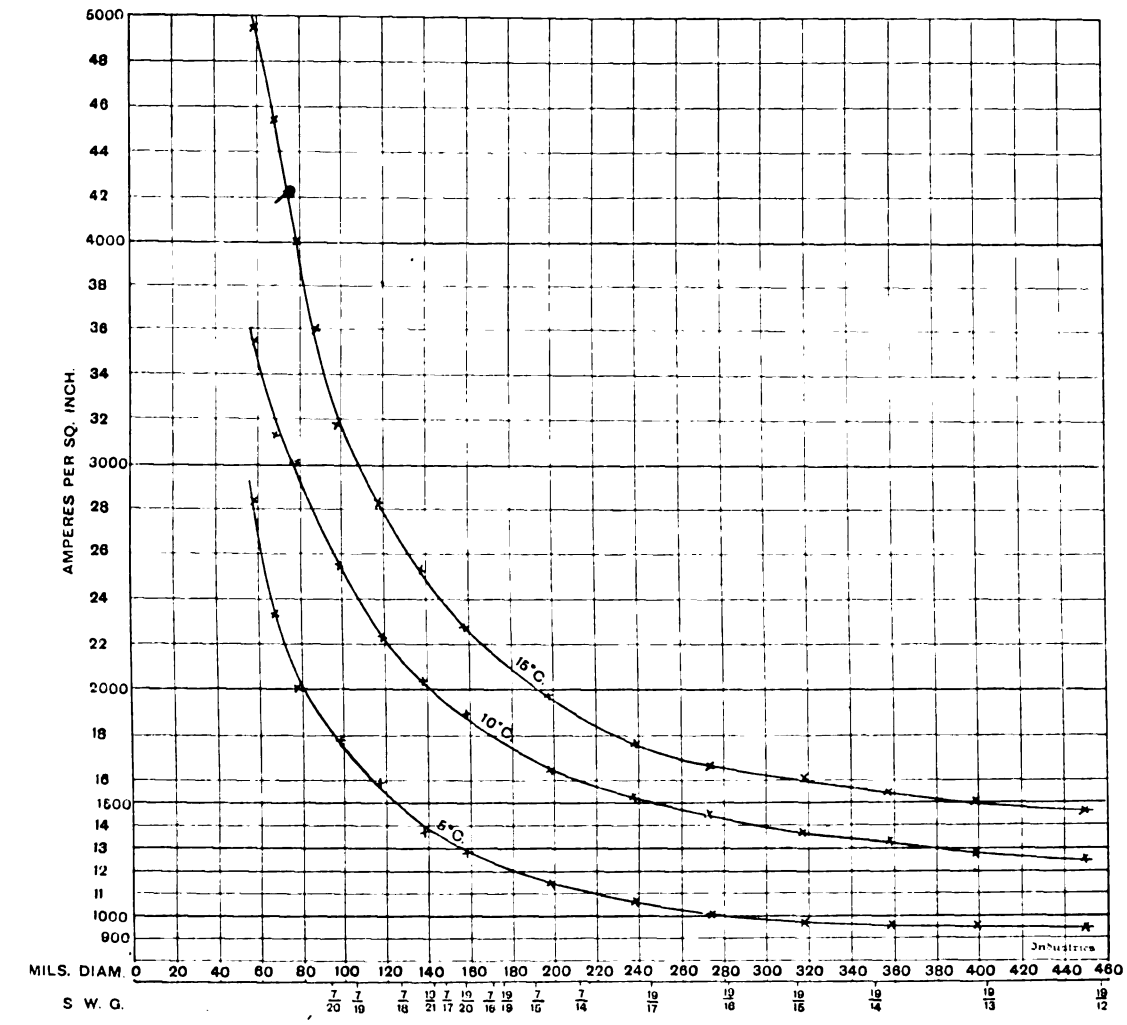
Constructed by Mr. William Johnson, Castleton Foundry, near Leeds.

THE HEATING OF CONDUCTORS BY ELECTRIC CURRENTS.

By Alex. P. Trotter.

The sizes of cables used for electric lighting are usually governed by the necessity for maintaining a uniform difference of potential between the mains and the lamps. Under some circumstances, generally when the distance between the mains and the lamps is very short, the required fall of pressure cannot be obtained without the use of correspondingly small conductors, and therefore a high density of current.

The Board of Trade has abandoned the rule which limited the density for currents up to 10 amperes to 2,000 amperes per square inch, and 1,000 amperes per square inch for heavier currents, and by the regulations recently published have prescribed a temperature limit.



"The maximum working current in any conductor . . . . shall not be sufficient . . . . in any case to raise the temperature to a greater extent than 30° of Fahrenheit's thermometer." It becomes therefore important to know what size of cable may in practice be used to carry a given current, when for any reason the Board of Trade regulation has to be observed, instead of the resistance of the conductor.

The paper contributed to the Society of Telegraph Engineers and Electricians in March, 1884, by Professor G. Forbes, treated the subject of heating of conductors, from a mathematical point of view, in a most exhaustive manner, and his results have recently been confirmed experimentally by Mr. A. E. Kennelly in a report read before the Edison Convention in America. The most useful portion of Mr. Kennelly's tests relates to wires covered with wooden casing under the ordinary conditions of house lighting. The wires are said to have had "the usual thickness of insulating covering." The results are given, partly as tables, and partly as curves. These may be compared with the curves contributed by the present writer to the discussion on Professor Forbes paper.

One of Mr. Kennelly's curves gives the currents which

Digitized by Google

HEATING OF ELECTRIC CONDUCTORS.

will raise wires of different diameters 15° C. This is near enough to the Board of Trade limit, and gives more than one degree margin. The author states that it is difficult to find any simple algebraic law, but suggests $560\ d^{\frac{3}{2}}$ where d is the diameter in inches, as a formula for the "current whose double raised the temperature 40° C."

Professor Forbes showed that with a simple suspended wire the heating is inversely as the sectional area, that is, the diameter squared, and the cooling is as the surface, that is, as the diameter; the temperature, therefore, is as the diameter $^{\frac{3}{2}}$, or $\sqrt[3]{\text{diameter}^2}$. But Mr. Kennelly admits that the conditions of an insulated wire in a wooden casing are of a very complex nature, and it is not surprising that the suggested formula does not fit the curve at all well. Since a wire of 0·1in. diameter is heated 15° C. by a current of 25 amperes, we may draw curves of $d^{1\cdot3} \times 25$, $d^{1\cdot4} \times 25$, $d^{1\cdot5} \times 25$, and plot the 15° C. curve among them, and it will be found that none of them fit the observed curve, which evidently is not of a power function of the diameter. Up to 0·34in. diameter the empirical formula $1000\frac{\pi}{4}d^2 + 156\ d$ fits the curve very closely.

Assuming that the solid wires, which appear to have been used, behave like the stranded cables which are used in practice, we may take from Mr. Kennelly's curve the following table, giving the sizes as stranded cables instead of the diameters of solid wires:—

S.W.G.	Amperes.	Amperes per sq. in.	B.W.G.	Amperes.
7/22	18	4,090	7/22	18
7/21	21	3,720	7/21	20
7/20	24	3,900	7/20	22
7/19	27	3,050	7/19	28
7/18	34	2,700	7/18	35
19/21	38	2,500	19/21	38
7/17	41	2,420	16/20	42
19/20	45	2,300	7/17	44
7/16	50	2,200	7/16	50
19/19	52	2,140	19/19	55
7/15	58	2,010	7/15	58
19/18	66	1,890	19/18	67
7/14	67	1,900	7/14	70
7/13	82	1,760	7/13	85
19/17	83	1,750	19/18	87
19/16	103	1,650	19/16	105
19/15	126	1,600	19/15	124
19/14	150	1,550	19/14	158
19/13	190	1,500	19/13	200

The striking feature of this table is the high density which is permissible under the new regulations; indeed, for a No. 18 wire a current of 11 amperes, at a density of 5,850 amperes per square inch, may, according to Mr. Kennelly, be used without raising the temperature more than 15° C. if covered with insulation and a wood casing.

The above curves show the relation between the density and the diameter of conductors in casing, for use of 5° C., 10° C., and 15° C. above the surrounding air. The readings for small wires appear to be somewhat irregular, but any small variation in the original curves, from which these were calculated, would appear very much exaggerated.

THE SOCIETY OF CHEMICAL INDUSTRY.

LIVERPOOL SECTION.

At the meeting held on the 15th ult. Mr. Douglas Herman exhibited and described a tower condenser made entirely of glass. The principle adopted is to divide the vertical height of the tower into sections of two or three feet, so arranged that each section shall carry the entire weight of packing material contained within it without pressing on the portion of the tower below it. A dangerous pressure in the lower parts of the tower is thus avoided, and the tower may be built to any height that is considered desirable. The sections consist of glass pipes with an upper external and a lower internal flange; the upper flange, resting on suitable supports, carries the whole weight of the pipe and its contents. The pipes taper slightly so that they can be fitted one into the other, the joint being made good by means of a suitable cement. A grid, consisting of pieces of slightly curved glass, $\frac{3}{4}$in. thick and $1\frac{1}{2}$in. deep, resting on the lower internal flange, carries the packing material, these grids being placed at right angles to one another in the successive pipes, so that the centre of distribution of the liquid is changed as it passes from one pipe to the next. The packing material may consist of glass of a twisted irregular form, and will weigh, with the supporting grid, about 1 cwt. per pipe; coke can also be used. Individual pipes, if damaged, can be removed and another substituted without interfering with the rest of the tower. The pipes are made about $\frac{3}{4}$in. thick, and in point of price will compare favourably with earthenware pipes doing the same amount of work. Mr. Herman pointed out that his tower satisfied one of the conditions insisted on by Dr. Hurter in his paper on the "Condensation of Hydrochloric Acid"—viz., that of providing ample cooling surface in that part of the apparatus in which the gas comes in contact with the condensing liquid. The pipes shown had a capacity of about three cubic feet and a surface area of over nine cubic feet. In this respect they appeared superior to earthenware.

At a later meeting held on the 5th inst. a paper was read by Dr. G. Schack Sommer, on "Home-grown Sugar for Great Britain and Ireland." The author pointed out that the popular impression had hitherto been that the climate of Great Britain and Ireland was too cold and too damp for the successful cultivation of beet, but he had no hesitation in saying that practical experience had proved the entire fallacy of this idea. In support of this statement, evidence given before a Select Committee of the House of Commons, by Mr. James Duncan and by Dr. Martineau, was quoted. Dr. Schack Sommer's experiments on the growth of beet had been made on farms at Wavertree (near Liverpool), and at Ballymitty, County Wexford, Ireland. Four kinds of seeds obtained from Dr. Scheibler, of Berlin, were used. As to the soil and manure required, wet and swampy ground was unsuitable; a loose clay with a well-drained bottom was what was wanted. A good artificial manure was one containing one part of nitrogen to two parts of phosphoric acid as superphosphate. In Germany as much as £6 per acre was spent for manuring. Stable manure was very efficient, but ought not to be used on the land within nine months of planting the beetroot seed. Lime was often of great advantage to the soil, but an addition of potassium salts had not proved remunerative. The proportion wanted was from 200lb. to 300lb. nitrate and from 400lb. to 600lb. superphosphate, or 400lb. to 500lb. Peru guano and 200lb. to 300lb. superphosphate per acre. The soil had to be ploughed up deeply—to a depth of 12in. to 15in. The percentage of sugar found varied from 14·2 per cent. to 18·2 per cent., a result comparing most favourably even with the beet grown in Germany, where an artificial method of cultivation had been in vogue for some time past. A small proportion of invert sugar was also found in the juice from the roots, due probably to the comparative poorness of the soil in which the beet was grown. At the Wavertree farm 42 tons 19 cwt. of beet were obtained per statute acre. Evidence was quoted by Dr. Schack Sommer to the effect that beet is by no means an exhausting crop; on the contrary, if planted with a due regard to rotation, it is not only a paying crop in itself, but it increases the fertility of the ground for wheat and other cereals. It is not possible to plant beet profitably oftener than once every fourth year. As regards the financial aspect of the question, the profit to the farmer, per acre, was set down at £5 15s. 6d. as a minimum—due allowance being made for the value of the beetroot pulp as a food for cattle, for which it is well adapted. Provided, then, that the necessary means were at hand for the manufacture of the sugar from the beet in this country, there was no doubt that the industry would prove commercially successful. At the same time the reader of the paper referred to the disadvantage under which this country suffered in respect to the home production of sugar, owing to the bounty system prevalent on the Continent. An interesting discussion followed, to which Dr. Schack Sommer replied.

A paper was also read, by Dr. S. G. Rawson, on a "New Form of Sprengel Pump, and on Apparatus connected therewith." The author described two new forms of pumps which he had constructed. One of these was a much simplified form of the ordinary apparatus, but equally efficient; the other more complex, but possessing several important advantages.

GLASGOW AND SCOTTISH SECTION.

On the 4th inst. Dr. J. B. Readman read the first part of a contribution on the "Manufacture of Phosphorus," and Mr. G. H. Gemmell a paper on "Moisture in Pulp."

Dr. Readman gave the results of his experiments under the heads of "Preparation of Phosphoric Acid," "The Concentration of the Acid," "Phosphorus Retorts and Furnaces," "Distillation," "Condensation, Refining, and Packing." His process differed much from that described in the text-books, which led to several of the members saying that they did not think that many of the statements made in these text-books were founded on facts. He afterwards gave the results of analysis, showing the small amount of phosphorus in boxes of ordinary matches of various makes, the quantity in all the matches in each box varying from half a grain to $2\frac{1}{2}$ grains.

Mr. Gemmell, in his paper, pointed out that straw or

Digitized by Google

wood pulp, as imported from Germany and Norway, contained a high percentage of water, varying from 40 per cent. to 50 per cent., but that the price of the material was based upon the amount of air-dried substance present. In the paper trade some pulp manufacturers sold their material on the basis that it contained 12 per cent. of moisture when air-dry, but paper makers did not generally allow more than 9 per cent. He had made a few experiments with a view of ascertaining what amount of moisture should be allowed, and the result of these was that 10 per cent. was about the mark. It was of interest to know this, for disputes often arose between buyer and seller over this question.

THE FUTURE SUPPLY OF INDIA-RUBBER.

Recent political proceedings in Brazil have brought into prominence the subject of our india-rubber imports, on which depends the success of one of our important industries. A failure in the supply of Pará rubber, whether caused by recklessly dealing with laws of exportation or natural laws in the forest, would fall heavily on many of our public and private interests. Hence it will be of interest to refer to what our authorities have been doing by way of providing against any such contingency. Considering that india-rubber comes next after sugar and coffee on the list of Brazilian exports, it appears strange that till recently so little attention was given to the way in which the substance was collected. The work was left to ignorant natives, and they destroyed millions of trees either by cutting them down or by their injudicious system of tapping. Latterly, however, the province of Amazonas has passed laws to regulate the season for tapping the trees, and has awarded premiums to encourage the planting of new forests.

Some twenty years ago the importance of the question of the future supply of rubber was recognised by our Government, and Mr. James Collins, of Edinburgh, was instructed by the India Office to draw up a report concerning the rubber trees of America, and to ascertain whether they could be grown in India. The results of his investigations were published in 1872. In 1875 Mr. Robert Cross, of Liverpool, in concert with Mr. C. R. Markham, of Assam, went to Panama to collect seeds and cuttings of the Central American rubber tree (Castilloa). He was also sent by the India Office in the following year to Pará to collect information about the Pará (Hevea) and Ceara (Manihot) trees, which produce the best rubber. The descriptions given in his official report show that he met with formidable difficulties in the course of his undertakings, but he succeeded in his main object. The seeds and cuttings which he obtained were duly sown and planted at Kew, and in due time dispersed over various botanical gardens in India and the Colonies. As trees, they are now flourishing at Madras, Calcutta, and Zanzibar, also in Burmah and Ceylon. The great superiority of the Pará rubber (Hevea) over all other kinds has ensured for it the most attention, but, notably in Assam and Northern India, its cultivation has been very much of a failure, though not equally so in Burmah and Ceylon. It requires an equable moist climate without extremes of temperature. The Castilloa tree was reported a few years ago to be doing well in Burliar and other places in Southern India. Some attempts have been made to grow the West African tree (Landolphia) in India. It is a hardy shrub, but takes up a good deal of room, and the quality of its products leads to some doubt whether it would pay for cultivation. From the botanical point of view we append a short list of plants producing india-rubber.

Nat. Order.	Genus.	Species.	Locality.
Euphorbiaceæ	Hevea	H. Braziliensis	Pará
	Manihot	M. Glaziovii	Ceara
Artocarpaceæ	Castilloa	C. Elastica	Central America, West Indies
	Ficus	F. Elastica	Assam, Rangoon, Java
Apocynaceæ	Hancornia	H. Speciosa	Pernambuco
	Urceola	U. Elastica	Borneo
	Vahea	V. Gummifera	Madagascar
	Landolphia	Various	West Africa, Mozambique

The above trees are to be met with in a broad zone parallel to the equator, where there is an isotherm of 70° F. Rubber is found as a milky fluid in the laticiferous vessels in the middle layer of the bark. It is coagulated by one of various methods, which include smoking over a wood fire, as in Brazil, or adding alum or a dilute acid, or by pouring the milky substance into hot water. The milk is very rarely met with in England, but we recently examined a good sample from Pará, and the proportion of rubber found in it—namely, 32 per cent.—was found to agree closely with earlier analyses by Adriani and Faraday. Before bottling the milk it is necessary to add some ammonia to prevent spontaneous coagulation. The most substance comes from the lower limbs of the Pará tree, which grows to great dimensions, and may be tapped at ten years' growth, but does not for twenty years reach its maturity.

From trees as they grow in untended nature, we may turn to some of the results that have been obtained from those that have been acclimatised. A report in 1881, from Dr. King, of the Calcutta Botanical Gardens, stated that the Ceara tree was the only one that promised good results, while the Pará and the Madagascar had utterly failed. This experience has been confirmed by Sir John Kirk, Consul at Zanzibar, who, in one of his official reports in 1882, said that the Ceara (Manihot) plants grew very well even in the worst soil, that they needed no attention, and that they commenced to yield rubber in five years, though not in a way to be remunerative. Nevertheless, the attempt to acclimatise American plants in Africa is an interesting one, and we cannot help wishing it an improved success, as manufacturers would be glad to receive clean rubber from Africa in place of the dirty resinous product of the Landolphias so generally imported into this country. In October, 1882, Dr. Trimen, of the Ceylon Botanical Gardens at Peradenya, sent to Kew a sample of the Central American rubber (Castilloa) produced from a cutting sent from Kew in 1876. This was examined by an expert, and reported to be of good quality, only deficient in tensile strength, owing perhaps to the immaturity of the tree from which it was taken. Colonial rubber is often being received at Kew, and submitted for examination, showing that this branch of economic botany is far from being neglected. Of Pará rubber from a Kew cutting, grown at Mergui, the first sample was received last season at Kew, and through the courtesy of Mr. Morris, the subdirector, we got a piece for examination. As in the above case, it was found wanting in tensile strength, and fell short of the best qualities of ordinary smoked Pará. The question is, whether the excess of its viscous over its fibrous constituents will be corrected in future tappings. It is not only in acclimatising foreign trees in India that work has been done, but, acting on Mr. Collins' report, the India Office have caused denuded districts to be replanted with the indigenous "Ficus elastica." Already in 1870 there was a plantation of these trees at Chardnar, in the district of Darrang, which covered a space of eighty square miles. This particular area has since been annually increased, and there has been planting in other districts besides. We may feel assured that the wanton destruction of rubber trees has practically ceased, and that the importance of securing an adequate supply of rubber for our future needs is fully recognised.

The financial side of the question can hardly be discussed till more reliable data have come to hand, but they are hardly likely to prove that undertakings in forestry bring any immediate or very early return. Dr. Trimen, for his part, feels confident that produce from Ceara trees will furnish an important item of revenue to Ceylon. It must be added that, in view of the competition in the case, other interested parties are not so sanguine of commercial success as he is.

THE LEAD IN THE WATER SUPPLY OF THE NORTHERN TOWNS.

The numerous cases of lead poisoning which have recently been recorded in the West Riding of Yorkshire, and in others of the Northern towns supplied with moorland waters, have at last induced the Water Committee of the Sheffield Town Council to undertake a thorough investigation as to the action of these soft moorland waters on leaden service pipes and cisterns, with a view to remedying this evil. At Mirfield, during the last twelvemonths, the medical officer of health has reported upwards of forty cases of lead poisoning, and Dr. Herbert, of Whitby, in a recent paper communicated to the Yorkshire branch of the Society of Medical Officers of Health, pointed out that most if not all of the towns supplied with moorland waters had suffered to an alarming extent. When such important towns as Sheffield, Bradford, Huddersfield, Rochdale, Keighley, Darwen, and Pudsey are all more or less affected by this evil, it appears to be a subject of such vital importance to the community, that we are surprised that the town councils have not combined together with the object of solving the difficulty. It seems somewhat unfair that Sheffield should alone undertake the investigation, and that the other towns should then reap the benefit of its labours. A combination of the whole of the infected district would naturally be able to engage in experiments of a larger magnitude and employ the best advice at a less cost per town than would otherwise be possible. Mr. Allen, of Sheffield, who is the analyst to the borough and also to the West Riding, has for some time been engaged on this problem, and has pointed out that the acidity of the water appears to have an important influence in increasing its solvent action for lead. At Sheffield the acid water only acts on the pipes, and the same fact has been observed at Huddersfield and Bradford. Many chemists have also pointed out that when lead is alternately in contact with air and water it is rapidly attacked, and the water is then found to contain appreciable quantities of lead. This is no doubt due to the oxygen of the air, as when the lead is always in contact with water only, whether under pressure or not, there is scarcely any action on the metal. It has also been found that many waters containing an appreciable quantity of free carbonic acid act upon lead, and that when such water is boiled, so as to drive off this excess of carbonic acid, the water then no longer acts on lead. Muller has also shown that distilled water, quite free from carbonic acid, but containing dissolved oxygen, has no action on lead, but on exposure to the air it absorbs acid and begins to attack the metal. The presence of chlorides, nitrates, organic matter, and ammonia in water do not influence its behaviour towards lead; while waters containing lime compounds, or carbonate of soda, have a marked action on the metal, although apparently in this instance the compound of lead formed is not soluble in the water, but remains as a protecting crust on the interior of the pipe. Carnelley and Frew have similarly pointed out that the corrosion of lead pipes by water is increased by the presence of air, and that sand, calcium carbonate, old mortar, calcium silicate, and a mixture of sand and calcium carbonate have a great protective action. The marked influence of sand in protecting lead from corrosion was also pointed out in the report of Crookes, Odling, and Tidy, on the action of water on lead, made to the Water Committee of the Corporation of Huddersfield in 1886, and Carnelley and Frew attribute this action to the formation of calcium silicate, as this body, or old mortar, is found by them to be more effective than limestone and sand, either separate or mixed. The theory of the borough analyst at Huddersfield was that sulphuric acid in the water caused it to act upon the lead pipes. At Leeds, where also the water supply is drawn from the moors, there have been no cases of lead poisoning. Here, however, the water, after passing through a large reservoir, is sent through iron pipes to the Wentwood filter beds, where, it is stated, its susceptibility to absorb lead is removed, or, at any rate, considerably reduced. Dr. Sinclair White, the former Medical Officer of Health for Sheffield, agrees with Mr. Allen that the solvent action is due to the presence of a certain amount of free acid of organic origin in the water supply from the high level, while others contend it is due to the absence of silica in the water. It will be seen from the above *résumé* of the opinion of experts on this much debated question that there are still conflicting views on the cause, or causes, of lead pollution. It is, however, worthy of notice that in Germany cases of lead poisoning from the water supply of the large towns are almost unknown, and that this is attributed to the fact that they are all supplied with water on the continuous system, and, therefore, there is no chance of the pipes becoming filled with air, as in England, where the intermittent water supply is common. Prof. Bunté, some time ago, pointed out that, although this might be the true explanation, it must be borne in mind that most of the German towns derive their water supply from waters which contain an appreciable amount of solid residue, and are therefore possibly not comparable with the soft moorland waters of our Northern districts. Last year Professor Percy Frankland contributed to the *Journal of the Society of Chemical Industry* a valuable contribution to this discussion, and as a result of his investigation he concludes that the activity of water towards lead may, according to its composition, be either increased or diminished by increased pressure. In those waters which contained oxygen an increase of pressure diminishes the activity of the water, while with waters containing carbonic acid no material alteration in the lead-absorbing power is noticed. Professor Frankland also has shown that, by very slow filtration through extremely divided flint, a small proportion of silica is dissolved, and that the water after such filtration has less action on lead. This statement is true both in the case of distilled water and all other soft potable waters examined by him, so that there seems a strong ground for generally adopting this method of filtration. Another important fact which has been brought out by this investigation is the reduction of the activity of a soft water by the addition of small proportions of carbonate of soda, which lends support to the acid theory of Mr. Allen and others, as the treatment with carbonate of soda would neutralise the acid. Sodium silicate might also possibly be found a convenient remedial agent to employ, as, by its use, not only would the acid present in the waters be neutralised, but silica would be added, and it would thus have a two-fold

Digitized by Google

retarding action. The Town Council of Sheffield were prepared some months ago to adopt the suggestion of Crookes, Odling, and Tidy that their water should be filtered through beds of limestone and sand, and were prepared to spend £100,000 on the experiment. Dr. Tidy attributed the action of limestone to the silica in it, but, as Mr. Allen has pointed out, it would be necessary to dissolve such an amount of limestone as would render the water intensely hard in order to get the half-grain of silica per gallon which Dr. Tidy has fixed as necessary to prevent the action on the lead pipes. The Sheffield Town Council have, however, still delayed action in the matter, and at their meeting last month appointed Professor Dewar and their consulting engineer, Mr. Hawksley, to assist their water engineer, Mr. Eaton, in an inquiry on "the tendencies, causes, and remedies of the Redmires water to take up lead," and we shall read their decision with interest, especially if in their report they are able to state that they have exhaustively examined into the merits and demerits of the various proposals which we have seen exist for the solution of this interesting problem. Possibly the problem may be solved in some such simple way as that adopted with success at Bradford, where they have mixed the soft acid water with their hard water supply, which has thus produced a water which is not only neutral, but has not yet caused any symptoms of lead poisoning.

Notes.

WOODEN VILLAS FOR SOUTH AMERICA.

A CARGO of villas has recentiy been despatched from Gothenburg, in Sweden, to Buenos Ayres. They were manufactured at the famous Ligna Works, and filled fifty railway waggons. This building of portable houses is becoming quite an important industry, both in Sweden and Norway. The villas are handsome, useful, and very cheap, and they have already found buyers in a number of different countries.

THE SAFETY OF THE ELECTRIC LIGHT.

THE *North American Review* having published articles from Edison and Westinghouse, who may be regarded as somewhat biassed authorities, now gives a paper by Sir William Thomson, who may be said to step in as a sort of impartial umpire. He says that with proper precautions the electric light is safe. Major Flood Page also writes a long letter to the *Times* in the same strain. The scare about the danger of the electric light seems to be dying out now; and, on the whole, it may have done some good, though it was carried a great deal too far. Reasonable care is wanted; and our Board of Trade and insurance rules ought to prevent any more bad work.

THE SKILLED LABOUR MARKET.

DURING the past month the labour market has been in a very disturbed condition, and the number of new strikes recorded has reached a high figure. In November the total was 92; in December, 57; but during January the number rose to 85, some of them being of considerable importance and affecting a large number of workers. In the cotton trade there were 15 stoppages in this way; in the coal trade, 10; among dock and wharf labourers, 10; in the woollen trade, 8; in the linen trade, 4; in shipbuilding, 5; in engineering, 4; and in brass hollow ware and wire-drawing, 6, in which 6,000 to 7,000 workers were involved. The remainder were among miscellaneous trades, such as brickmakers, bacon-curers, locksmiths, &c. In spite of these elements of disturbance, however, the societies representing the chief skilled trades sending in monthly statements make reports of a highly satisfactory character. In almost every case an improvement is to be noted on the figures of the previous month. In the few instances where an increase in the number of unemployed is to be observed, the change is so slight that in the aggregate the total increase is but 93; while, on the other hand, the decrease of the number of members out of work is so marked that the total is 673, a net reduction on the month of 580. In all, 21 societies have reported. These have a total membership of 211,855, of which 3,044 are out of employment, as against 3,624 for the previous month, and 7,397 for the corresponding month of last year. The proportion per cent. is this month 1·44, while for the month before it was 1·75, in the corresponding month of ast year 3·1, and in the February of 1888 7·8. In the shipbuilding trade the percentage of unemployed has only n one previous year been less—that is, in 1882, although since then the number of men engaged in this industry has increased by at least 20 per cent. Not one in each hundred of the men in this trade is out of work at present, the correct proportion being about 9 per 1,000. Almost equally prosperous are all the branches of the engineering trade, which has not been so well employed since 1873. Despite the earliness of the season, the building trades are showing signs of improvement. In the steel, iron, and coal industries work is plentiful. The textile trades are moderately employed, but are stationary. The printing and book trades are also fairly busy. A general summary of the remarks made in the reports shows that 14 societies report their trades as "very good," three as "good," and four as "moderate."

EXHIBITION OF MINING AND METALLURGY.

IN our London letter some weeks ago, we mentioned briefly that a proposal was on foot to hold this year, in London, an Exhibition of Mining and Metallurgy. Matters have now progressed so far that particulars are available. It will be opened early in July at the Crystal Palace, and continue for three months; entries are to be made by the 15th of March at the offices, 18, Finch Lane, E.C. The list of persons connected with the enterprise contains the names of many prominent men connected with the mining and metallurgical industries, and we understand that the support promised from the Colonies and from abroad is considerable. The subjects embraced in the scope of the Exhibition include machinery in motion, mining plant of all kinds, the manufacture of iron, steel, zinc, copper, and alloys, the petroleum industry, salt mining, the nitrate and phosphate industries, electricity in its application to mining and metallurgy, and sundry minor sections. It is somewhat to be regretted that the site of the Exhibition is so far out of town, for the Crystal Palace is not the most convenient site for business men.

THE GLASGOW CHAMBER OF COMMERCE AND THE PROPOSED FORTH AND CLYDE CANAL.

IN a recent note we mentioned that the Government had declined to undertake any financial responsibility in connection with the proposed Forth and Clyde Canal, and we pointed out that at present the schemes must be discussed on their commercial merits. The Glasgow Chamber of Commerce has dealt with the matter in a very summary manner. In reply to a communication from the Edinburgh Chamber of Commerce respecting the proposed canal, and from the Belfast Chamber desiring to be informed of the views of the Chamber respecting it, after a discussion of the matter, it was unanimously agreed that the Glasgow Chamber could not support the memorial of the Edinburgh Chamber, believing that the proposed canal was unnecessary, and that, financially, it would not be successful. Before discussing this decision we will wait till further information is published about both of the proposed routes, but it must be evident that the decisions of the Government and of the Glasgow Chamber of Commerce reduce the probabilities of either of the schemes being carried out to a very considerable degree, and therefore make it absolutely necessary for their promoters to bring forward the strongest possible evidence in their support.

TELEGRAPHS IN CHINA.

THE progress of telegraphs in China during the past few years has been very great, and it shows that as soon as the Government of the country is satisfied that any Western art or science is required by the people, or at least can be introduced without causing any upturning of social or industrial arrangements, and, especially when it adds to the defence of the country, it sets about its introduction with great vigour. For thirty years the Chinese were aware of the advantages which foreigners derived from the employment of telegraphy, but they did not think that the conditions of the country required it, and it was not until 1877 that a start was made by the Great Northern Telegraph Company. The campaign of 1880 in Kuldja showed the necessity of a speedier means of transmitting news to the army, and the same thing was demonstrated in the troubles with France in Tonquin. Since these dates great extensions have taken place, and now we learn that the Chinese telegraph system adjoins that of the French in Tonquin and that of the Russians at Kiachta, and that in a few months the junction will be complete. While the military uses of the telegraph have always been kept prominently in view, it has also become of great importance for commercial and general purposes and all the latest important information is now sent from Europe to China, so that the telegraph is likely to be a very important factor in the awakening of China.

A FEDERATION OF COAL OWNERS.

A POWERFUL federation of coal owners has been arranged, which is intended to include all the coal districts in England except those of South Wales, and of Northumberland and Durham, where at present sliding scales exist for the regulation of wages. It is proposed to raise in connection with the federation a large fund in order to resist, in case of emergency, what the employers consider unfair demands on the part of the miners, either in regard to wages or the restriction of output. It is said that the feeling of the coal owners is strongly that the demand for an eight hours' day from bank to bank must be resisted to the utmost, not alone in the interests of the owners themselves. It would mean, as a rule, only six hours' actual work per day, and the coal owners contend that this would result in a reduction in the total output of the country of not less than thirty million tons per annum, and an increase of the price of coal to the consumer by something like 5s. per ton. If this be so, it is a very serious matter, and we trust that no hasty steps will be taken by either party, but that the questwill be fully considered in all its bearings.

TECHNICAL SCHOOL AT GARTSHERRIE.

THE Scotch Technical Education Act has now been in existence for more than two years, and up to the present time its effect has been null. Now, however, the Old Monkland School Board has obtained the necessary permission from all the authorities mentioned in the Act, and arrangements have been made for the erection of a new science and art school at Gartsherrie. It is intended chiefly for evening classes, for the benefit of those engaged in work during the day, although certain day classes will also be held. The work of the school as hitherto conducted in other buildings seems to be carried on strictly in accordance with the requirements of the Science and Art Department, and the new buildings are being arranged to suit these. They will include several class rooms, mechanical and architectural drawing rooms, a chemical and a mechanical laboratory, with the necessary smaller rooms for preparation and administration. The work done in the school has hitherto depended largely on the support of the employers of labour in the neighbourhood, and has been very successful. Whether that success will continue when it has become a formal piece of official administration is a point on which many have doubts. If Technical Education Acts only lead to the separation of the interest of the employers from the schools they will confer a very doubtful advantage.

BASIC STEEL IN 1889.

THE official statistics of the Thomas-Gilchrist steel industry have just been completed for the twelve months ending December 31st, 1889, and show that the total make of steel and ingot iron from phosphoric pig during this period amounts to 2,274,552 tons. This is an increase of 321,318 tons over 1888, and brings the total production of basic steel to the enormous amount of 10,845,000 tons. Last year's make by the basic process includes 1,764,639 tons of ingot iron, containing less than ·17 per cent. of carbon. The following table gives the statistics for the various steel producing countries during the year:—

	1889. Total Make.		1889. Ingot Iron.
1. England	493,919	...	348,828
2. Germany and Austria	1,481,642	...	1,185,323
3. France	222,393	...	159,271
4. Belgium and other countries	76,599	...	71,217
Totals	2,274,552		2,276,476

	1888. Total Make.		1888. Ingot Iron.
1. England	408,594	...	276,476
2. Germany and Austria	1,276,070	...	1,026,033
3. France	222,333	...	158,223
4. Belgium and other countries	46,237	...	32,300
Totals	1,953,234	...	1,493,032

From last year's total of 2,274,552 tons there was produced an amount of slag estimated at 700,000 tons, and containing about 36 per cent. of phosphate of lime. The greater portion of this slag has already been disposed of as a fertiliser and for cement making.

Patent Record.

(Compiled from "The Illustrated Official Journal (Patents).")

APPLICATIONS FOR PATENTS.

(The names in italics within parentheses are those of Communicators of Inventions.)

ENGINEERING.

3rd February, 1890.

1785. Hannaford, C. E. ..... Weighing machine.
1797. McGregor, W. ..... Roofs.
1803. Appert, L. ..... Apparatus for moulding glass. (29th August, 1889.)
1806. Conley & Lancaster ... Apparatus for making steel.
1814. Preston, Marshall, & Cotton ..... Lathes.
1817. Jobson, A. ..... Boiler furnaces.
1820. Gurney, H. ..... Kiln for burning bricks.
1821. Phillips & Lewis ..... Application of copper to ships, &c.
1824. Messenger, T. ..... Ratchet gear.
1827. Barnes, S. K. ..... Furnace flues.

4th February, 1890.

1837. McGovern, B. ..... Waggon wheels.
1840. Vanorman, O. ..... Car axles. (31st August, 1889.)
1846. Clegg, Clegg, & Townend ..... Looms.
1847. Meredith, O. ..... Tubes for steam boilers.
1856. Wilkinson, R. T. ..... Railway rails.
1858. Arnold & Arnold ..... Boilers.
1862. Scott & Davis ..... Machines for covering wire.
1863. Wilson, J. ..... Wire rope machine.
1864. Booth, J. ..... Machines for pile fabrics.
1870. Reinecker, J. E. ..... Steam hammers.
1871. Fleshman, B. F. ..... Combined running gear and steering apparatus.
1875. Lightfoot, T. B. ..... Refrigerating machinery (*Linde*).
1877. Riedler, A. ..... Compressing air.
1882. Stubley, C. H. ..... Sifting apparatus.
1888. Totten, R. C. ..... Castings.
1890. Maxon, Coleman, & Boyer ..... Drive chains.
1892. Wheeler, N. ..... Sewing machines.
1893. Berrenberg, A. ..... Air pumps.
1901. Brown, I. ..... Permanent way.
1904. Cole & Waller ..... Steam engines.

5th February, 1890.

1907. Bingham, G. C. ..... Machine tool for making milling cutters.
1911. Marks, G. C. ..... Tubular shafting (*Ogilvy*).
1916. Lindsay & Lindsay ..... Looms.
1919. Ellison, J. B. ..... Apparatus for gassing yarn.
1921. Gibbs, C. ..... Condensing steam in brewing coppers.
1927. Pope & Pope ..... Self-acting feed for materials, grain, or minerals.
1932. Hood, G. C. ..... Lowering and detaching boats.
1937. Kirk, J. H. ..... Looms.
1942. Rodewald, F. A. ..... Boats' tillers.
1943. Abel, C. D. ..... Oil engines (*Gas Motoren Fabrik Deutz*).
1948. Deacon & Driffield ... Apparatus for separating liquids from solids.
1955. Ross, J. ..... Breechloading small arms.
1958. Robinson, M. H. ..... Steam valves.

6th February, 1890.

1961. Batchelor, J. G. H. ..... Boiler tubes.
1968. Booth & Beaumont ..... Machinery for condensing fibres.
1970. Sellars, G. ..... Pressure filters.
1973. Gäbel, R. ..... Cutting tool for lathes, &c.
1976. Steel, A. ..... Lubricators.
1991. Lamb, H. ..... Thrust blocks for propeller shafts.
1997. Price, Sen., & Valentine Machinery for cleaning flues.
2001. Statham, F. T. ..... Root cutting machines.
2003. Jensen, P. ..... Machines for forming articles from wood pulp (*Christensen*).
2004. Jensen, P. ..... Pit saws (*Blom*).
2006. Taylor, F. ..... Ploughs (*Taylor*).

7th February, 1890.

2010. Bacon, W. R. ..... Wire stitching machines.
2014. Sayer, W. ..... Air propellers.
2021. Dearden & Dearden ... Machinery for sawing stone.
2024. Curtis, J. ..... Looms (*Stancliffe*).
2038. Steele, T. ..... Railway couplings.
2040. Dick & Jones ..... Metal plates, tubes, or bodies adapted to facilitate the absorption and transmission of heat or cold.
2041. Rütgers, G. ..... Attaching rails to sleepers.
2043. Stevenson & Little ..... Drying machines.
2044. Kohn, O. ..... Rotary engines.
2045. Newton, A. V. ..... Firearms (*Nobel*).
2050. Haddan, H. J. ..... Rotary engines (*Dow*).
2053. Stephens & Stephens ... Machinery for drilling rock.
2055. Mills, B. J. B. ..... Apparatus for heating liquid and gaseous bodies (*Scigle-Goujon*).

8th February, 1890.

2062. Dyer, S. ..... Spinning frames.
2063. Holecek, A. ..... Water-tube boilers.
2064. Davies, C. A. ..... Boilers for manufacture of paper-pulp (*Kellner*).
2066. Schofield, Haslam, & Hargreaves ..... Looms.
2069. Muter, D. D. (on behalf of The Carlton Press, Ld.) ..... Printing machine.
2070. Sahlström & Hill ..... Furnaces for burning liquid fuel.
2072. Hardaker, W. ..... Jacquard machines.
2081. Dracup, C. H. ..... Jacquard mechanism for looms.
2085. Hay, A. ..... Fireproof doors.
2086. Hearth, Hearth, & Willis ..... Circular knitting machines.
2088. Hearth, Hearth, & Willis ..... Straight bar knitting frames.
2089. Thompson, W. P. ..... Tanks for storing petroleum (*Vaillant*).
2093. Stevenson, A. ..... Sieving machines.
2094. Haddan, R. ..... Air pump (*Desir*).
2096. Reid, Fisher, & Parkinson ..... Jacquard machines.
2105. Nobes & Jackson ..... Signalling on railways.
2106. Neher & Frey ..... Magazine gun. (24th July, 1889.)
2109. Wade & Cherry ..... Motor pump.

ELECTRICITY.

3rd February, 1890.

1784. Garrett, T. A. ..... Production of ozone by electricity.

4th February, 1890.

1867. McMullen, J. A. ..... Electrical conduits.
1878. Williams, J. B. ..... Insulating compounds.
1897. Farrig, E. ..... Electrical insulating composition.

5th February, 1890.

1939. Bougault, M. H. L. ..... Electric temperature alarm.

6th February, 1890.

1987. Wohle, S. ..... Electro-plating metals with aluminium.

7th February, 1890.

2056. Lebenberg, S. ..... Telephone receivers.

8th February, 1890.

2080. Chamberlain, J. C. ..... Storage batteries. (10th July, 1889.)
2091. Thompson, W. P. ..... Secondary batteries (*Gibson Electric Company of Europe*).
2108. Whitmore & Akester ... Switches for controlling electromotors.

CHEMISTRY.

3rd February, 1890.

1794. Pfeiffer, C. ..... Extraction of gold and silver.
1808. Imray, O. ..... Colouring matter (*Society of Chemical Industry in Basle*).
1811. Holliday, R. ..... Colouring matters.
1812. Holliday, R. ..... Dyeing wool.
1813. Holliday, R. ..... Dyeing textile fibres.
1816. Ewens, G. W. ..... Purifying sewage, &c.
1828. Willcox, B. ..... Colouring matters (*Farbenfabriken vormals Friedrich Bayer & Co.*).

4th February, 1890.

1842. Mayer & Lorrain ..... Recovery of float gold.
1848. Davis, A. R. ..... Distillation of ammonia liquors.
1874. Imray, J. ..... Colouring matters (*La Societe Anonyme des Matières Colorantes et produits Chimiques de St. Denis & Chapuis*).

5th February, 1890.

1913. Thompson, W. P. ..... Utilisation of scrap tin (*Carez*).
1914. Spence & Spence ..... Alum.
1946. Wright, J. ..... Purifying water.
1951. Maxim, H. S. ..... Explosives.

6th February, 1890.

1962. Bang, A. ..... Yellow dyestuffs (*Dahl & Co.*).
1964. Kibble, W. O. ..... Sulphuretted hydrogen.
2002. Shenton, G. ..... Aluminium (*Berg*).

7th February, 1890.

2057. Campion, A. J. ..... Smelting tin ores.

MISCELLANEOUS.

4th February, 1890.

1900. Drexler & Drexler ... Roof coverings.

5th February, 1890.

1933. Hood, G. C. ..... Scattering oil to calm the sea.
1934. Fifield, C. ..... Paving and building stone.
1947. Wilson, G. ..... Fire escape.

7th February, 1890.

2048. Rubin, E. ..... Bullets.

8th February, 1890.

2076. Horton, A. ..... Instrument for indicating vertical positions in ships.
2077. Barlow, E. S. ..... Water and gas pipes.
2107. Casebrook & Perry ..... Fire escapes.

COMPLETE SPECIFICATIONS ACCEPTED.

Notice is given that all persons interested in opposing the grant of a Patent on any one of the under-mentioned Applications may, at any time within Two Months after the date given, give notice at the Patent Office, in the prescribed form, of such opposition.

Year 1888.

17565. Rietsche & Kaiser.

1889.

9. Holloway.
1984. Hearsey.
2093. Julius Fredrick Moore Pollock & George Henry Collins.
2956. Fitch.
3192. Morton.
3213. Ayrton & Perry.
3526. Salamon.
3753. Row.
4112. Owens.
4432. Ingle.
4561. Thompson (*Delatour*).
4645. Parr (*Haake*).
4670. Sturgess, Brown, Brown, & Brown.
4847. Williams.
4914. Bland (*Parcy*).
4990. McGregor.
5090. Shaw & Christiansen.
5225. Dormer.
5288. Manoschek & Manoschek.
5341. Gabet.
5428. Eckardt.
5500. Watson.
5569. Hartley.
5615. Timmis.
5629. Hoyle & Hoyle.
5644. Shouler.
5662. Barlow.

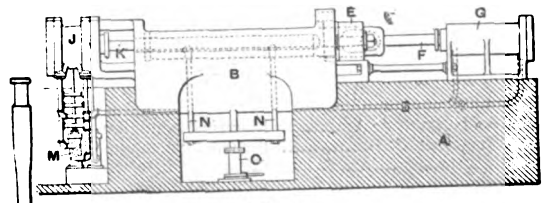
ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.

ENGINEERING.

Lathes.—*J. J. Holzapfel & G. W. Budd, London.*—A silent driving appliance and automatic stop are here described for use upon lathes and other machines. In the illustrations Fig. 1 gives a side elevation, and Fig. 2 an end elevation of a lathe head with the appliance attached. A large worm-wheel is fixed to the lathe mandril and geared to the tangent screw or worm D. The screw D has fixed to its shank the second worm-wheel C, in which gears the tangent screw B driven by the V pulleys A. The pulleys A are driven by a band from an overhead motion, and cause the mandril of the lathe to rotate slowly. For automatically stopping the revolution of the mandril a sliding rod L is constructed provided with adjustable stops N. A pin M in the worm-wheel on the mandril strikes the stops N in its revolution and causes the rod L to slide in its bearing and throw the screw B out of gear from the worm-wheel C. The action of the rod L in throwing the screw B out of gear is more clearly shown in Figs. 3, 4, and 5. The screw B is held down in gear with the worm-wheel C by a hook F pivoted upon the spindle I. On the spindle I rests the saddle-piece K, which is attached to the end of the rod L. When the rod L is depressed the part T presses on a pin in the

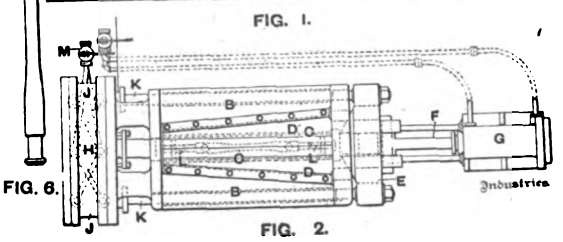


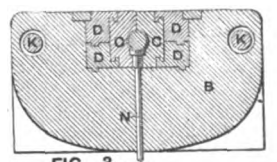
spindle I and causes the latter to rotate and move the hook F off the supporting frame of the screw B. The screw B thus rises from the action of a spring fixed beneath it, and the rotation of the mandril is stopped. If the rod L is raised by M coming into contact with the other stop, the spindle I is rotated by the part U of the saddle K as may be seen from the illustrations, and similar actions take place to those already described. The appliance is attached to the lathe head by a screw W, so that it can be easily and quickly removed. Claims: (1) The construction of an apparatus for giving a slow and regular movement to the spindle or mandril of a lathe arranged substantially as above described, so that the motion in either direction of the mandril's rotation can be arrested either automatically or by hand, independently of any movement that may be occurring in any other part of the lathe, and which apparatus is removable at will in manner above described; (2) the construction of an apparatus for giving a slow and regular movement to the spindle, mandril shaft, or screw of machines other than lathes arranged substantially as above described, so that the motion in either direction of the rotation of the spindle, mandril shaft, or screw can be arrested either automatically or by hand, and which apparatus is removable at will in manner above described.—No. 2136. February 6th, 1889. 8*d*.

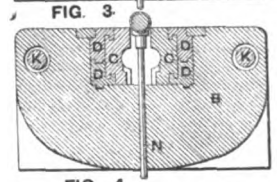
Sand Blast Apparatus.—*J. E. Mathewson, Sheffield.*—The improvements described in this invention refer to recovery or separating of sand from the blasts of air in sand blast machinery after the sand has operated upon the work. The principle involved is the same as that described by the inventor in a previous patent, No. 2456, 1887, for removing the priming from steam. The steam in its course is given a whirling motion by passing through a helical passage, and the water is thrown off by centrifugal force. In the present case the sand-laden air is led to and through a helical passage, and receives a similar whirling motion, causing the sand to fly through perforations in the cylinder which surrounds the helical discharge aperture. A second cylinder surrounds the perforated one, and collects the thrown-off sand, which is in a dry state and ready to be used again. Claims: (1) Drawing or forcing air laden with solid particles through a helix into a slotted or perforated cylinder, whereby a whirling motion is communicated to the air, and the solid particles are discharged tangentially through the slots in the cylinder; (2) the means as herein described for separating or recovering sand and other solid particles from blasts or currents of air charged with such particles; (3) an apparatus for separating solid particles from currents of air, the combination with a helix and perforated cylinder of an outer concentric casing provided with radial baffle plates, and with or without exhauster or fan.—No. 4032. March 7th, 1889. 8*d*.

Bearing for Shafts and Crank Pins.—*S. Z. de Ferranti, London.*—The main object of the invention is to ensure the crank shaft of an engine resting equally in its bearings throughout the whole length. To effect this the bottom block of the bearing is curved on its underside to the form of part of a cylinder which has its longitudinal axis at right angles to the axis of the shaft and in the same horizontal plane. The curved underside of the block rests in a correspondingly curved seat formed for it on the upper side of a base plate. The base plate is flat on its under side and capable of swivelling in a horizontal plane. With a bearing such as described it will be seen that the bearing surface for the shaft may assume any position. To prevent the parts of the bearing heating, passages are formed in them for the circulation of water. The bearing block of a connecting rod is made to swivel in the same manner as that described. Ten claims are made for the block described and modifications.—No. 1902. February 2nd, 1889. 11*d*.

Manufacture of Railway Axles.—*H. Aiken, Homestead, Pennsylvania, U.S.A.*—This machine is designed to form the entire axle in one operation. The axle is formed from a blank piece of shaft, which is heated and placed between powerful dies closed by hydraulic pressure. The dies are of the shape of the finished axle, and are closed by wedge pieces worked by the hydraulic power. In the illustrations, Fig. 1 is an elevation of







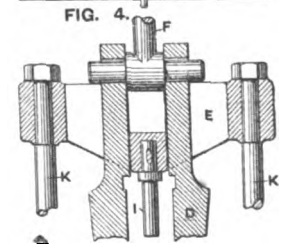


FIG. 2.

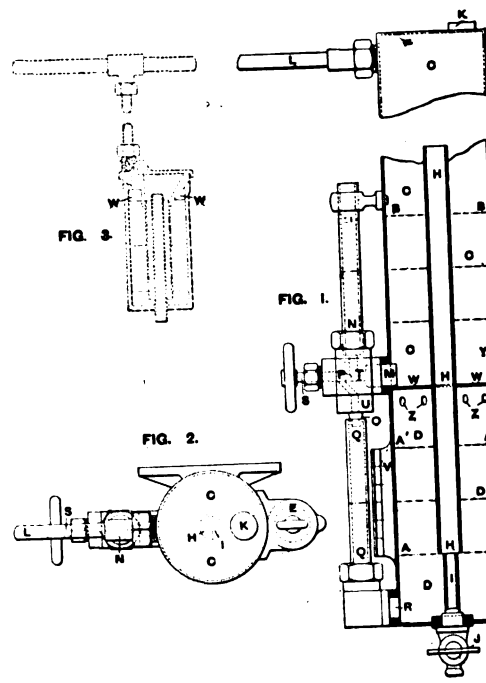
the apparatus, Fig. 2 a plan, Figs. 3 and 4 sections upon the body B. Fig. 5 a section upon the part E, and Fig. 6 a finished axle. The appliance is mounted upon a suitable foundation A. It consists of a strong iron body B, in which are inserted the dies C and the wedges D for closing the dies. The wedges and dies are grooved (see Figs. 3 and 4) to ensure the latter opening when the former are withdrawn. The wedge pieces D are connected by shanks to the crosshead E, to which is also connected the piston rod F of the hydraulic cylinder G. At the opposite end of the body B is another and larger hydraulic power cylinder H, which actuates a plunger L at that end of the dies. Two other smaller cylinders J are placed upon each side of the cylinder H, and have their pistons connected by rods K to the crosshead E. To the crosshead E is attached a second plunger L. Valve



mechanism M controls the supply of water to the cylinders. Rods N, worked by hydraulic power in the cylinder O, discharges the finished axles from the dies. The method of proceeding is as follows:—A blank piece of round bar iron, rather smaller in diameter and longer than the required axle, is heated and placed between the dies C. Fluid pressure is now admitted to the cylinder G, and the wedges thus forced in, causing the dies to close and firmly grip the blank. Next fluid pressure is admitted to the cylinders H and J, thereby forcing the plungers L inward, upsetting the ends of the blank, and finishing axle. The plungers are then retracted, and the axle discharged by the rods N. Nine claims are made for the machine above described.—No. 9287. June 4th, 1889. 8*d*.

Bobbins for Spinning, &c.—*W. R. Sidebottom, Stockport.*—In this specification a method is described for imparting rotary motion to bobbins or tubes used in certain cotton spinning and doubling machines. The bottom part of the bobbin or tube is made parallel and cylindrical to drop into a cup or socket fitted to surround the lower part of the spindle. The top of the bobbin or tube is provided with a small hole to fit loosely the top of the spindle, and so keep the tube in an upright position. The cylindrical part of the tube that fits the cup upon the spindle may be made to taper upwards a little in order to fit it more tightly. The rotation of the spindle causes the tube to be forced into contact with the cup on the spindle, so that rotary motion is imparted to the tube or bobbin. This invention enables bobbins or tubes provided with "heads" being employed in ring-spinning and ring-doubling machinery, the cups upon the spindle ensuring the bobbins a uniform height and vertical position on the spindles. Claim: The hereinbefore described method of maintaining loose bobbins or tubes in position upon and imparting rotary motion to them by means of the spindles of machines for spinning and doubling cotton and other fibrous materials, which method consists in so forming the bobbins or tubes and the spindles that when such a bobbin or tube is placed in position upon such a spindle and such spindle is rotated, the bobbin or tube will be forced into contact with a part upon the spindle, and have rotary motion imparted to it, and be kept in position upon the spindle by the rotation of such spindle.—No. 2112. February 6th, 1889. 8*d*.

Lubricating Apparatus.—*S. Banner, Sunderland.*—In a previous patent, No. 18943 of 1888, the inventor describes a method and apparatus for lubricating surfaces by the use of air pressure. In the present invention improvements are made in that part of the appliance which supplies the air and indicates the action of the feed. In Fig. 1 is shown a sectional elevation of the appliance in broken connection with a lubricator, Fig. 3. Fig. 2 is a plan of the appliance. The vessel is divided into two compartments C and D. At the top of C is the outlet L for conducting air to the lubricators, and an opening K for filling the chambers. At the back of the vessel is fixed the air-pump E, which is operated by the spring G and by the motion communicated through the cord F from an oscillating part of the machine. The pump communicates with the top chamber by a small aperture Y. On the front of the vessel are gauge glasses N and Q, which communicate with the top and bottom chambers by the ports M and R, and to each other through the valve P. Behind the gauge glass Q is a scale to indicate the depth of

liquid which is in the chamber D. The chambers also communicate by a pipe H, and the lower one is provided with a valve I, by which liquid can be removed from the chamber to the depth indicated by the line A, A. The apparatus is worked as follows: The top chamber is filled with oil to the level B B, the height assumed to correspond with the level of oil in the lubricators. The bottom chamber is filled to the height A A. The pump is now started and air is forced into the top chamber, where it has two means of escape, one through the supply-pipe L to the lubricators, and the other down the pipe H through the chamber A, and out of the vents Z. At the same time oil is allowed to drop through the valve P under pressure due to the head of liquid in C into the glass Q and chamber A. The height of oil is thus gradually raised in the chamber A, and the air has a resistance now in escaping through the pipe H equal to the pressure due to the increased height. This resistance to the escape of air causes the air in the chamber C to exert upon the surface of the oil a pressure that compensates the diminished head, and so the oil flows through the valve P under a constant pressure and indicates the action of the lubricators by the scale and glass Q. The compensating action is communicated to the lubricators through the pipe L. Four claims are made.—No. 1554. January 29th, 1889. 8*d*.

Stamps for Crushing Ores.—*P. J. Ogle, London.*—In practice a gravitation stamp cannot be driven above a certain speed, for if driven faster the impetus imparted to the stamp by the cam would cause it to rise above its path, and so prevent it completing its downward stroke before the cam is in the position to again raise it. To enable the stamps to be driven faster, they are provided, according to this invention, with an elastic buffer or spring, which opposes the tendency of the stamps to rise, and gives more force to its downward stroke. A simple form of this invention is a coiled spring surrounding the stem of the stamp above a tappet fixed to the stem; as the stamp is raised, the tappet compresses the spring, and so retards the upward movement of the stamp. Claims: (1) In an ore-crushing mill the employment of buffers

Digitized by Google

for preventing the stamps from rising above their normal height, whereby such stamps can be driven at a greater speed than heretofore; (2) the application to an ore-crushing mill of buffers arranged as described; (3) the manufacture and use of stamp mills having elastic buffers arranged as described.—No. 1619. January 29th, 1889. 6*d*.

Expansion Gear.—*H. Kühne, London.* (*W. R. Proell, Dresden, Germany.*)—The improvements refer to that form of expansion gear in which steam is admitted by two slide valves, one working on the back of the other. In this invention the main slide valve is of the usual form, excepting that the admission ports at the outer face of the slide valve have the shape of arcs. The second slide valve, or expansion plate, is a circular disc, having on its back a stud whose axis coincides with the axis of the disc. To the stud of the expansion plate is fitted a lever, which is oscillated by a suitable eccentric upon the engine shaft. The disc is given by this oscillating lever a movement that causes it to alternately open and close the arc-shaped admission ports of the main slide valve. The motion of the disc being in an arc, its outer edge is subjected to more friction than the inner edge, and, as the disc is free to revolve upon its axis, it assumes different positions whilst at work, and so grinds itself straight and tight on the back of the main slide valve. Claims: (1) In expansion gear for steam engines the combination with a main valve having in it arc-shaped admission ports of a circular plate or disc free to turn on its centre, and connected with an expansion eccentric or equivalent device as described; and (2) and (3) the arrangement and combination of parts as described and illustrated in the specification.—No. 3475. February 27th, 1889. 6*d*.

Machines for Knitted Pile Fabrics.—*J. Booth, Halifax.*—This invention consists of the application of a series of hooks and circular cutters to straight-bar knitting machines for the purpose of severing the pile loops as they are formed. By the application of this invention to machines hitherto only available for the manufacture of knitted looped fabrics, such pile fabrics as plush seals and the like may be produced. The illustrations show Fig. 1, a sectional end elevation of a straight-bar knitting machine with the appliance attached; Fig. 2, a front elevation of the same; Fig. 3, a front elevation, with part in section; and Fig. 4, details of the machine. A are the hooks and B the circular cutters, employed in combination with the guides

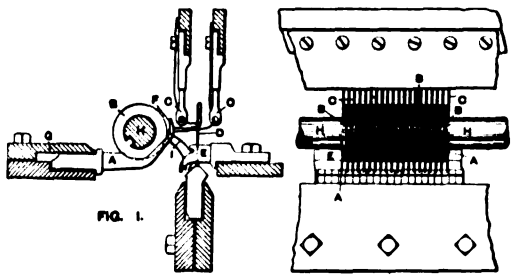


FIG. 1.

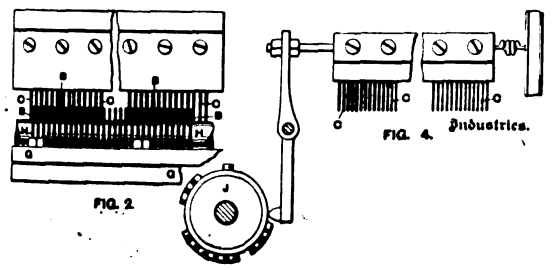
FIG. 3.



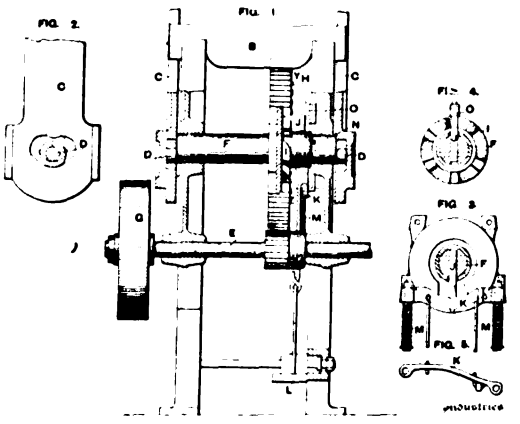


FIG. 2.

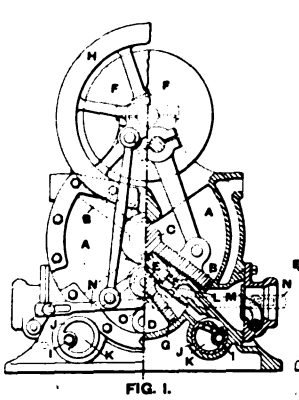
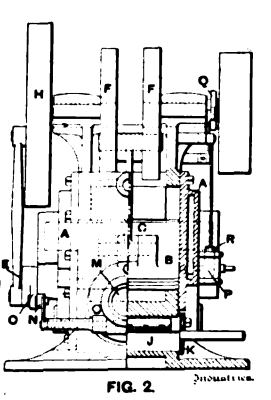
FIG. 4.

C, the needles D, and the sinkers E of an ordinary machine. The points F of the hooks are free, but the shanks are secured in bars of spelter or lead, and clamped in a continuous manner between the plates G. The hooks are arranged in pairs, and between each pair is a circular cutter B, which is secured to a shaft H. As the pile loops I are formed, they are passed over the points of pairs of the hooks A by the guides C, which receive a lateral motion from the peg wheel J, Fig. 4. The loops collect upon the hooks A until those first made slide down and come into contact with the knives B and are severed. By this arrangement a number of the loops are always upon the hooks, which ensures the effectual tying in and securing of the pile loops. Claim: The improvements in machines for knitting and cutting pile fabrics, wherein are employed revolving circular cutters or circular knives, working between cranked hooks or stems, such as illustrated, in combination with the needle, sinkers, and guides of a straight-bar knitting machine as described.—No. 2872. February 19th, 1889. 8*d*.

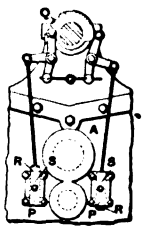


Carding the Backs of Cords, &c.—*J. Brindle, Manchester; R. L. Reade, Sale; J. Taylor, Sale; and J. M. Moulson, Manchester.*—The object of this invention is to effect the carding or perching of the backs of woven fabrics, such as cords, fustians, &c., in the loom and during the process of manufacture. To accomplish this a sliding bar, or preferably a roller, is mounted at the front portion of the loom underneath or behind the cloth. The roller or sliding bar is covered with carding material and has motion given to it by suitable gearing connected to the ordinary working parts of the loom, such that the bar has a reciprocating motion or the roller a rotary motion. In the case of the sliding bar the card is pressed to the cloth when moving in one direction only, but in the case of the roller the card may be pressed thereto continuously or intermittently, as found most desirable. Claims: (1) The employment in a loom during the operation of the weaving of a roller clothed with wire card and mounted underneath the woven fabric, at or near the front breast beam of the loom or other convenient point, and giving, by means of suitable gearing with the working parts of the loom, an intermittent or continuous motion to such card clothed roller, for the purpose of perching the back of the fabric; (2) the employment in a loom during the operation of weaving of an oscillating or reciprocating bar, clothed with wire fabric and mounted underneath the woven fabric at or near the front breast beam of the loom, or other convenient point, and giving, by means of suitable gearing with the working parts of the loom, reciprocating motion to such card clothed bar, for the purpose of perching the back of the fibre.—No. 2878. February 19th, 1889. 6*d*.

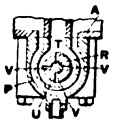


Heeling Machines.—*T. Peberdy, W. Earp, & T. H. Parr, Leicester.*—The machines referred to are employed for building heels and attaching them to the boots and shoes. The invention consists of improvements in the gear for raising the bed upon which the building and attaching stands are placed, and in the method of starting and controlling the machine by an automatic clutch arrangement. In Fig. 1 is shown a side elevation of the machine partly in section. The building and attaching stands (not shown) are placed upon the bed plate B, which are supported by the guides C. In the guides C work the studs D of an eccentric shaft F, so that by the revolution of F the table B is raised and lowered. Upon the shaft F is a loose gear wheel H, which is geared to the driving belt pulley G as shown. When working the machine, the driving wheel is kept running, and revolves the wheel H upon its shaft F. To put the bed-plate in motion for a length of time sufficient to complete one operation, a clutch arrangement is devised for coupling the shaft F to the wheel H. Details of the clutch are shown in Figs. 3 and 4, of which 3 is a section upon the line Y Z, Fig. 1. The clutch is constituted by a ratchet face I, into which engages a catch J pinned in a slot in the shaft F. The catch J is normally held away from the face I by a guide bar K, which is controlled by a foot lever L and springs M. By

FIG. 1.



pressing the foot lever, the guide K is lowered and permits the catch J to be pushed forward by the spring N into the clutch I. The shaft then revolves with the wheel H, and the roller O attached to the catch J keeps the latter in contact with the face I by rolling upon an annular plate. During this revolution of the shaft F, however, the foot lever has been released and the guide guide bar K assumed its original position, so that as the shaft completes its revolution the roller O passes behind the guide K and withdraws the catch from the face I. The slots for the eccentric studs in the slide C are shaped as shown in Fig. 2 to make the bed-plate rest whilst the pegs are being driven into the heel. Claims: (1) In a heeling machine the combination with a clutch such as I of a lever such as J mounted in the shaft which carries the clutch and adapted to be engaged with the clutch by a cam-bar such as K substantially as and operating in the manner and for the purpose herein described and illustrated in the accompanying drawings; (2) in a heeling machine the combination in the vertical slides C of a groove or slot shaped or adapted to cause the block and die to remain compressing the heel during the ascent of the plunger substantially as described; (3) the improved machine constructed, arranged, and operating substantially as and for the purpose herein described and illustrated in the accompanying drawings.—No. 1889. January 12th, 1889. 8*d*.



Gas Engines.—*W. E. Crist, Brooklyn, & H. C. Covert, New York, U.S.A.*—The engine is constructed with a double oscillating piston and separate compression chamber, and explodes a charge of gas each stroke. In the illustrations, Fig. 1 is a side elevation of the engine, half in section; Fig. 2 an end elevation, half in

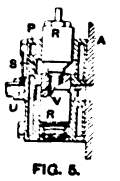


FIG. 1.

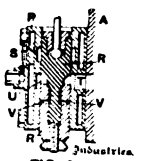

FIG. 2.

section; and Figs. 3, 4, 5, and 6 show an improved igniting chamber. A are the chambers in which the double piston B oscillates upon the centre C. Below the chambers A is the compression chamber D, in which oscillates a piston G upon its centre E. The piston B is connected to the crank discs F, and the piston G to a pin in the fly-wheel H of the engine. The chambers A communicate by the valves L to the compression chambers, and by the valves M to the exhaust. The chamber D communicates to the valves J, which supply the gaseous explosive. In the valves J the gas is supplied by the tube I and the air by the larger space K. The cycle of the engine is as follows:—The fly-wheel is revolved, and the piston G sucks in the gaseous compound from the valve J. Upon the return stroke of the piston G the charge is compressed and passed through the valve L into the chamber A, where it is immediately exploded. The piston B makes its outstroke under the force of the exploded charge, and upon its return exhausts the charge through the valve M, which is operated by a lever N attached to the crank O. The cycle of operations is the same upon each side of the engine, the explosion upon one side taking place at the time the other is exhausting. The pistons B and G, when in motion, move towards and away from each other, but the piston B commences its out-stroke a little before the piston G completes its compression stroke to facilitate the opening of the spring valve L to admit

FIG. 3.

FIG. 4.

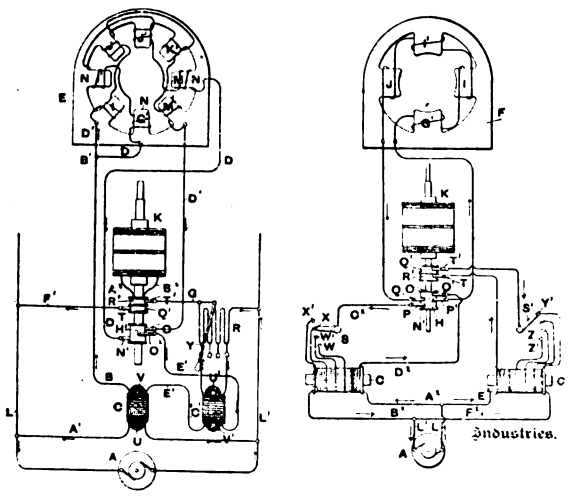
FIG. 5.

FIG. 6.

the charge to the chamber A. The igniters P are placed at the back of the engine, and operated by a cam Q fixed to the crank shaft, as shown in Fig. 3. The igniter is composed of a double piston R, which puts the flame vent S in and out of communica- with the firing port T, as shown in Figs. 5 and 6. In Fig. 5 communication is shown made through the annular space U and the vent holes V. In Fig. 6 the communication is shown broken, the piston R having been lowered by the action of the cam Q. Six claims are made for this form of gas engine and the igniter.—No. 20249. December 17th, 1889. 8*d*.

ELECTRICITY.

Bases for Electrical Instruments.—*F. L. Rawson, London.*—The bases are composed of a composition formed of about six parts by measure, of Portland cement with one part of plaster of Paris, treated in the following manner:—The plaster of Paris and Portland cement are mixed with sufficient water to form a paste suitable for moulding. In some cases a small proportion of sand may be added, not more than two parts. The paste is moulded in a mould to the desired shape, and such metal parts as are required are bedded in it. When the material has set it is removed from the mould and slowly dried for several days. The moulded article may be further hardened by immersing it in a solution consisting of equal parts of silicate of soda and water. When the moulded article is sufficiently dry and hard it is heated to about 220° F. and plunged in a bath of liquefied ozokerit or paraffin wax, or material which is the heavy oil or residue of paraffin. In making boxes or tanks which cannot be conveniently immersed in a bath of molten material the following method is adopted:—A closed vessel is placed in the moulded box, leaving sufficient space around it to receive the impregnating substance. This vessel is then charged with steam, and the impregnating material becoming liquefied is allowed to soak through the moulded article. Claims: (1) The method of preparing bases and other insulating parts of electrical apparatus by moulding them of a mixture of Portland cement and plaster of Paris, drying the moulded articles, heating them, and impregnating them with heavy oil; (2) bases and other insulating parts of electrical apparatus consisting mostly of Portland cement and plaster of Paris moulded to shape and impregnated with heavy oil or analogous material.—No. 2176. February 7th, 1889. 6*d*.



Measuring Electric Currents.—*W. H. Dines, Esher, & L. W. Gatward, Hitchin.*—The recording mechanism of this measuring appliance is driven by a flow of water, and the flow is regulated by the electric current passing through the machine. A small tipping cistern is balanced upon knife edges, and constructed with a long discharging pipe. The mouth of the discharging pipe is over another small vessel, which automatically tilts and discharges its contents as it becomes filled. This small vessel is connected to the recording mechanism so as to indicate the number of times it becomes filled or the quantity of water discharged. The tipping cistern has attached to it the core of a solenoid, whose weight holds the vessel normally such that the mouth of its discharge pipe is at the same level as the water within the cistern. The water in the tipping cistern is supplied from a main cistern and kept at a constant height. When a current is passed through the solenoid its core is lifted, and depresses the end of the tipping cistern discharge pipe so that water flows into the measuring vessel at a rate depending on the current. The deflection given to the tipping cistern discharge pipe is proportional to the square of the current, and the rate of efflux of the liquid is theoretically proportionate to the square root of the pressure or head, hence the registration of the instrument can be accurately judged. For alternate currents the solenoid would be replaced by suitable controlling coils. Claim: The principle by which the flow of electricity is measured by the rate of efflux of a liquid, the pressure or head causing that efflux being made to depend upon the strength of the current.—No. 656. January 14th, 1889. 6*d*.

Electrically Driving Vehicles.—*P. B. Elwell, Deauville, France, & J. K. Starley, Coventry.*—Improvements are claimed in the method of applying electromotors to wheels for driving vehicles such as railway carriages, tramcars, &c. It is designed to enable such wheels to be driven independently of each other, so that one wheel of a pair may run faster than the other in

Digitized by Google

travelling round corners or curves. Instead of mounting the electromotor so that only the field magnets or only the armature revolves, both are caused to revolve in opposite directions, and the armature is applied to one wheel and the field magnets to the other. The method of mounting these parts to the driving wheels is as follows:—At the outer end of the armature spindle is mounted a crank or eccentric carrying an externally toothed wheel held by a spring or lever from revolving upon its own centre. The toothed wheel engages in an internally toothed wheel firmly attached to the axle of one driving wheel in such a manner that upon the crank revolving the inner or externally toothed wheel is carried round the inner periphery of the internally toothed wheel, imparting to it a powerful, but slow motion. On the outer end of the field magnet spindle is also mounted a crank or eccentric; but in order to obtain a reversed motion, it carries the internally geared wheel, and the externally geared wheel is attached to the driving wheel. Claims: (1) In electrically driven vehicles the application to the wheels of such vehicles of a motor in which the impulse between the armature and field magnet (or magnets) forms a perfect differential motion; (2) in electrically driven vehicles, the use of internally and externally toothed gearing in combination with cranks or eccentrics, and springs or levers, as and for the purposes described; (3) in electrically driven vehicles the general arrangement of motor and gearing as described.—No. 2567. February 13th, 1889. 8*d.*

Electric Motors.—*W. P. Thompson, Liverpool.* (*The Westinghouse Electric Company, Pittsburgh, U.S.A.*)—The class of motors referred to is that operated by alternating electric currents, and the object of the invention is to construct a motor that will readily start from rest. The magnetisation of the field magnet is carried to a very high point of saturation at the commencement and gradually decreased as the motor increases its speed. In the accompanying illustrations Fig. 1 gives a general organisation of circuits and apparatus for carrying out the invention and Fig. 2 a second application of the same. In Fig. 1 A is the source of electric supply from which conductors L and L^1 lead to the commutator Q^1 R^1 of the armature K. A conductor A^1 leads from the conductors L L^1, and includes the primary coil of a converter C whose secondary coil is connected by B to the field magnets E of the motor, and the conductor B is divided at B^1, each branch passing round alternate poles of the magnet and afterwards connected to the brushes N^1 O of a commutator H^1. A brush O^2 applied to the commutator H^1 makes alternate contact with the plates X against which the brushes N^1 O rest. This brush O^2 is connected to the secondary coil of the converter C^1 and thence to the remaining terminal of the secondary coil of C. It will thus be seen that the secondary circuits of the converters C and C^1

are completed alternately through the conductors D D^1, thus causing the poles of the armature to be alternately vitalised. The primary circuit of the converter C^1 is connected in a shunt upon a resistance R which is included in a conductor G leading from L^1 to a contact brush T^1. A second contact brush T is connected up to L. The rings of the armature Q^1 R^1 are connected up to the armature coils. When the machine is started the resistance R is included in shunt upon the converter C^1, so that the maximum difference of potential is applied to the primary coil of the converter. The secondary current thus induced is combined with that being produced by the converter C, and serves to magnetise the field magnet E to a high degree of saturation. The armature is meanwhile supplied with currents through F1 and G. As the rotation of the armature increases in rapidity the resistance may be gradually cut out, and so diminish the difference of potential at the terminals of the primary coil and its magnetising effect upon the field magnet. When the resistance R has been completely short-circuited the converter has no further effect, and the converter C then operates alone to maintain the magnetic field at its proper value.—Eleven claims are made.—No. 3272. February 23rd, 1889. 8d.

Testing Electric Conductors.—*W. Lowrie & C. J. Hall, London.*—The conductors are tested for insulation whilst in use by an apparatus which indicates their conduction by light or the absence of light. The appliance employed consists of a vacuum discharge tube, usually known as Geissler's tubes, enclosed in a small box. The tube is connected to terminals upon the outside of the box, and the box provided with an aperture to observe the effects of the tests upon the tube. In testing a high potential conductor one of the vacuum tube electrodes is connected to one pole of the conductor, whilst the other tube electrode is connected to earth. If the insulation of that portion of the conductor is bad the characteristic glow of the vacuum tube is wanting, because earth connection is made at the extremities of the testing circuit. On the other hand, if the insulation is good the glow of the tube is present, because current is discharging through the vacuum tube to earth. Both poles of the conductor should be tested to see which is the faulty side of the cable. A standard vacuum tube can be used with the first, illuminated by other sources of electricity to enable comparisons to be made. In the case of currents of low potential an induction coil and a make and break apparatus is connected with one of the poles to be tested and put to earth, whilst the vacuum discharge tube is placed on the secondary circuit. The result is that if there is a leak on the portion of the conductor under test no light is given upon the pole, because earth is made at both extremities of the tube. But if light is given it follows that the insulation of the opposite conductor is more or less bad because the inducing current which discharges (by induction) through the vacuum tube must pass through the imperfect portion of the conductor to earth. Seven claims are made.—No. 1166. January 22nd, 1889. 8*d.*

CHEMISTRY.

Treatment of Ores.—*E. B. Parnell, London.*—By treating the ores according to this process they become softened to such an extent as to enable rolls and such machines to complete the disintegration in place of the heavy stamps usually employed. The quartz or other ore is first heated to a fair red heat in a suitable furnace, and then immersed in its heated state in water. The result is that the ore becomes so softened that it can be crushed with great ease. A form of apparatus that may be employed to heat the ore consists of a horizontal tube, through which the ore is propelled by a helical revolving screw mounted upon a hollow shaft. Into this tube, through perforations in the hollow shaft, is drawn air which has been previously heated by any suitable furnace. At the time the ore reaches the end of the tube it becomes sufficiently heated by the air, and is discharged into a tank of water. The ore is next raised by an elevator to a second tube, which is similarly constructed to the first, and has passed through it the air proceeding from the first, for the purpose of drying the ore. The ore is delivered from the last tube into the hopper of the rolling or other machine. Instead of discharging the ore from the first tube into a tank of water as above described, the ore may be discharged on to an endless band, which would carry the ore under a shower of water and into a suitably constructed drying oven before finally dropping it into the hopper of the rolling mill. Six claims are made for the treatment of ore as described and the apparatus employed in the process.—No. 2,931. February 19th, 1889. 8*d.*

A Substitute for India-rubber.—*S. Kenyon, Warrington.*—The substitute consists essentially of a preparation of oxidised linseed oil, such as the skins and refuse of boiled oil. In carrying out the invention oxidised linseed oil is mixed with a liquid in which it will dissolve or with which it will combine when heated. The solvent material preferably used is the distillate produced in the manufacture of varnish from gums or gum resins, although varnish foots, pine oil, or thick pine grease, resin, resinous oil, or a mixture of two or more of these or other similar substances will also act as solvents when heated. The varnish distillate or other solvent is placed in a pan or still heated by steam or otherwise, and the skins of boiled oil or oxidised oil added and mixed well together (or they may be mixed prior to being placed in the pan). The proportion of the solvent to the oxidised oil will altogether depend on the consistency of the product desired. To make the product of about the consistency of raw india-rubber one part of the varnish distillate to three parts of the boiled oil skins is used, but to produce a substance of a thick treacly consistence equal parts of each. The mixture in the pan is then heated to about the temperature of boiling oil, say 350° to 450° F., and maintained at that heat for a considerable time until all the hard or oxidised masses of the oil are dissolved in or thoroughly incorporated or combined with the varnish distillate or other solvent used (say from twelve to twenty-four hours). Claims: (1) A substance applicable as a substitute for india-rubber, also for waterproofing and for other purposes, prepared from the skins of boiled oil or oxidised linseed oil dissolved in varnish distillate or other solvent; (2) the process of manufacturing or producing a solid or semi-solid or viscous soluble substance from the refuse skins of boiled oil or oxidised linseed oil which consists in mixing the skins or oil with varnish distillate, varnish foots, pine oil, resin or resinous oils, and boiling the mass at a high temperature in a suitable pan or still until the two are thoroughly combined.—No. 4477. March 14th, 1889. 4*d.*

Explosive Compounds.—*H. S. Maxim, Crayford, Kent.*—In the manufacture of explosive compounds, according to the present invention, dissolved gun-cotton or pyroxyline is mixed with nitro-glycerine, nitro-gelatine, or similar material, and with oil, preferably castor oil. The inventor has discovered that the addition of castor oil, or other suitable oil, to compounds of dissolved gun-cotton and nitro-glycerine, nitro-gelatine, or the like, increases the toughness of the product and modifies the explosive properties thereof, whilst greatly diminishing its liability to deterioration by exposure to the atmosphere. Castor oil is preferably employed, because it is soluble by means of the solvents which are employed for dissolving the gun-cotton and nitro-glycerine or nitro-gelatine. The improved explosive compound is advantageously manufactured as follows:—First dissolve gun-cotton or tri-nitro-cellulose in acetone, ethylic acetate, or a similar solvent, either in a liquid state or in the form of vapour, until the said gun-cotton is brought to a sufficiently thin consistency, and then add to the dissolved gun-cotton the nitro-glycerine or nitro-gelatine, and after that the castor oil, and thoroughly incorporate these substances. Or the castor oil may be dissolved in a portion of the acetone, or other solvent, before the solvent is added to the gun-cotton. When the mixture is sufficiently dissolved, it is subjected to pressure in a cylinder, and so forced out through small holes in the form of threads or strips, which may be cut into small pieces as already explained by us in these columns (Vol. VII., page 508) in a description of a previous invention, No. 16213 of 1888. Claims: (1) An explosive compound consisting essentially of gun-cotton or pyroxyline mixed with nitro-glycerine, nitro-gelatine, or similar material, and with castor oil or other suitable oil; (2) the manufacture of an explosive compound by first dissolving gun-cotton by means of acetone or other solvent and then incorporating with the dissolved gun-cotton, nitro-glycerine, nitro-gelatine, or similar material, and castor oil or other suitable oil; (3) the manufacture of an explosive compound by dissolving first castor oil or other suitable oil and then gun-cotton by means of acetone or other solvent, and incorporating therewith nitro-glycerine, nitro-gelatine, or similar material; (4) the manufacture of an explosive compound by first mixing nitro-glycerine, nitro-gelatine, or similar material, and castor oil or other suitable oil, with a small quantity of acetone or similar solvent, treating dried gun-cotton with this mixture in a rotary cylinder or chamber, and then subjecting the product, in a cylinder or chamber from which air is exhausted, to the action of vaporised acetone or other solvent, and then to pressure.—No. 4477. March 4th, 1889. 6*d.*

Dyeing and Printing Fibres.—*B. Willcox, London.* (*F. Bayer & Co., Elberfeld, Germany.*)—This invention relates to an improved process for fixing colouring matter, such as the azo-dyestuffs, which possess the property of directly dyeing unmordanted cotton in an alkaline bath, and which are known in the trade as substantive colouring matters, on or in the animal or vegetable fibres to which they are applied in the processes of dyeing and printing. The said substantive colouring matters possess the property of forming with the salts of the earthy and of the heavy metals lakes which in part are very permanent. By boiling in a solution of a metallic salt goods which have been dyed or printed in the usual way, the metal becomes fixed by the colouring matter in the form of a fixed lake. The results obtained naturally vary according to the nature of the metallic salt and colouring matter employed. Zinc is found to be best suited for use in dyeing wool and silk, as it has no influence whatever on the colour, and forms lakes which perfectly resist the action of boiling water and better resist fulling or milling than do the original colours. The zinc can be employed in the form of sulphate of zinc or white vitriol. Woollen goods dyed in the usual way, with deltapurpurine for example, are boiled for a few minutes with a quantity of white vitriol corresponding to the dye employed. The zinc is then completely taken up from the bath. The wool so treated is now faster to fulling or milling, and can be acted on with boiling water without suffering in the least. The dyestuffs are preferably employed in printing with an addition of neutral thickening paste. Claims: (1) The process of boiling animal fibres dyed or printed with any substantive cotton colouring matters such as those hereinbefore mentioned, with a solution of zinc salts, especialy white vitriol; (2) the process for dyeing and printing with substantive cotton colouring matters, by boiling animal and vegetable fibres (which are dyed or printed with such colouring matters) with a solution of copper salts, and especially with blue vitriol; (3) the process for dyeing and printing with those substantive cotton colouring matters which result from the combination of the tetrazo compounds of the diamines such as those hereinbefore named with (*a*) two molecules of salicylic acid or cresol-carboxylic acid, or with (*b*) one molecule of salicylic acid or cresol-carboxylic acid, and then with another molecule of any amine, phenol, or their sulpho or carbo acids, the said process consisting in printing the dyestuff in neutral thickening in the presence of a chromium salt, or in treating animal or vegetable fibres dyed or printed therewith with a solution of a chromium salt.—No. 3,934. March 6th, 1889. 6*d.*

Colouring Matters.—*B. Willcox, London.* (*F. Bayer & Co., Elberfeld, Germany.*)—This invention relates to the manufacture of new acid green dyestuffs. The inventors have discovered the general rule that in the case of the tetra-alkylised product of the diamido-triphenyl-methane series (which are green dyestuffs), the colouring power increases as the molecular weight is decreased. The improved process may be stated as consisting in condensing benzaldehyde or nitrobenzaldehyde with two different tertiary amines in the presence of a dehydrating agent, then converting the unsymmetrical substituted diamido-triphenyl-methane derivatives thus obtained into leuco-sulpho acids by means of sulphonating agents, such as concentrated sulphuric acid, fuming acid, or sulphuric mono-chlorhydrine, the resulting unsymmetrical substituted diamido-triphenyl-methane sulpho acid being then converted into the green dyestuff by an oxidising process. By sulphonating the bases produced by the new process and oxidising the resulting sulpho acids, valuable new dyestuff sulpho acids can be obtained, of which the trimethyl benzyl-diamido-triphenyl-methane derivative and the unsymmetrical dimethyl-dibenzyl-diamido-triphenyl-methane derivative are the most important products. Claims: (1) A process for the production of unsymmetrical substituted diamido-triphenyl-methane derivatives consisting in condensing benzaldehyde or meta-nitrobenzaldehyde with a mixture of two different tertiary amines in the presence of a dehydrating agent substantially as hereinbefore described; (2) the process for converting the unsymmetrical substituted diamido-triphenyl-methane derivative referred to in the preceding claiming clause into leuco sulpho acids by treating with sulphuric acid, fuming acid, or monochlorhydrine; (3) the process for converting the unsymmetrical substituted diamidotriphenyl-methane-sulpho acids obtained according to the process of the second claiming clause into green colouring matters or dyestuffs by oxidising the same; (4) as new articles of manufacture the products obtained by the means hereinbefore described and claimed by the preceding several claiming clauses.—No. 1046. January 19th, 1889. 6*d.*

Silicon Bronze.—*G. E. Vaughan, London.* (*L. Weiller, Angoulême, France.*)—In alloys of copper containing silicon or sodium improvements are made according to this invention in their tenacity and ductility by the addition of zinc or spelter. The new alloys are formed by bringing those of copper containing silicon or sodium to a state of fusion and then adding the zinc or spelter in quantities varying as the resulting alloy is required to approach the nature of brass or bronze. Three claims are made.—No. 18,211. December 13th, 1888. 6*d.*

Copies of the British specifications may be obtained on application to H. Reader Lack, Esq., *Comptroller-General, Patent Office, Southampton Buildings, London, W.C. The published price must be remitted, together with a sum sufficient to cover postage, which may be reckoned at ½d. for every* 10*d. or fraction of* 10*d. Remittances exceeding one shilling must be made by Post Office Order.*

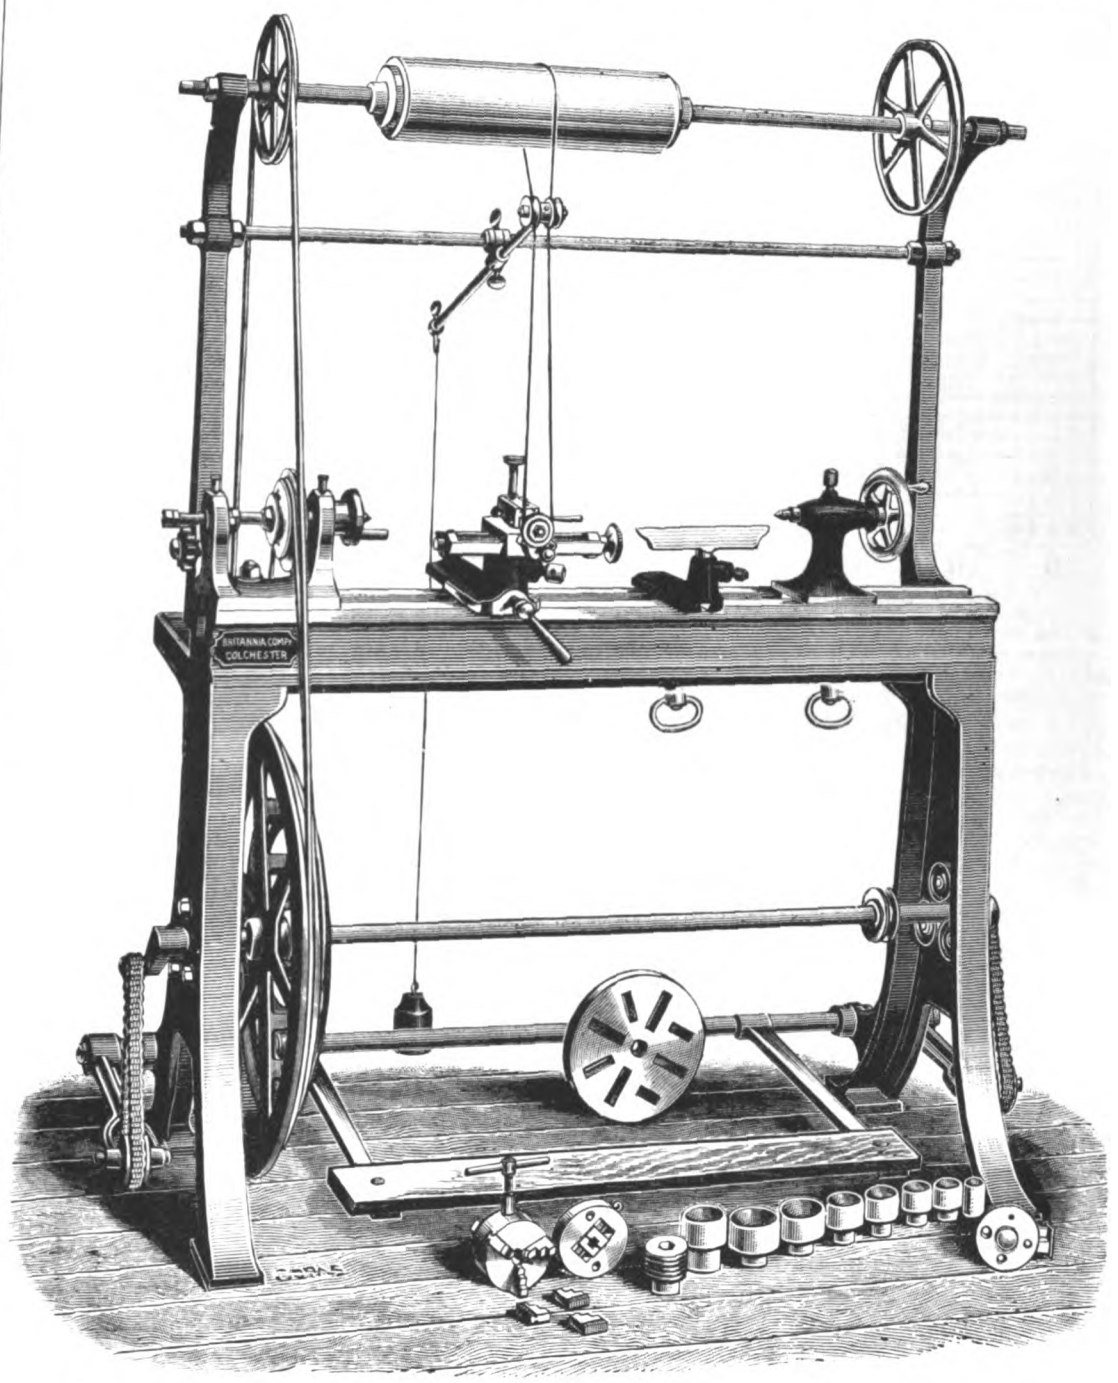
THE "LUKIN" LATHE.

THE Britannia Company, Colchester, have recently brought out a new lathe, which we illustrate herewith. The fast headstock is made with a steel traversing mandril which runs in hardened steel collars, and is fitted with six screw guides or "formers" of different pitches. The guides work in a segment plate, which is adjustable in and out of gear by means of an eccentric motion. A plain sleeve is used in place of the screw "former" when plain turning is to be done. When screw cutting is only temporarily interrupted, a simple device is provided to avoid taking off and putting on the screw guide and sleeve. The cone pulley is made of gun-metal, with three or four speeds, and its front is fitted with a division plate having three or more circles of holes. A driver, chuck, and face plate are fitted. The loose head or poppet is fitted with a steel tubular mandril, coned at the front end for the centre, and screwed at the back end and fitted with a left hand square thread traversing screw. A plain hand rest and tee-fittings for wood and metal are fitted.

TRAINING FOR TRADES AND CRAFTS.

BY HENRY DYER, C.E., M.A.

(*Continued from page* 147.)



II.

THE great majority of boys of the working classes leave the elementary day schools when they are about thirteen years of age, and those of the middle classes leave the secondary schools when they are about sixteen. At the earliest of these ages it is quite absurd to expect them to have acquired much in the way of technical education, nor indeed should it be attempted. The moral nature should be trained, not by the dry inculcation of theological dogmas, but chiefly by the example and direct teaching of the masters, for the permanent influence of a teacher depends not so much on what he teaches as on what he is. If all our teachers were men of wide culture and with high ideals of the duties of citizenship, we should have less of that narrow selfish spirit in the world which is at the root of a great many of the difficulties with which we are now confronted. If we wish our boys to become manly men and good citizens, we must be careful to appoint manly men for their teachers, and not merely learned pedants or skilled artificers, whose minds are very often narrower than those of the boys they undertake to educate, many of whom enter school or college with enthusiastic ideas of what they would like to do in this world, and who leave it narrow-minded scholars. Moreover, it must be distinctly remembered that, "if education is to be a prevailing power, it must be something which the auctioneer's hammer cannot fix the value of, something that the highest bidder cannot buy, a gain in the man himself. The auctioneer's view will never command the hearts and lives of the young."* This may seem a digression, but as a matter of fact it is the foundation of the whole matter. All history, especially the history of the industrial cities of the middle ages, shows us that an ounce of manly pride and enthusiasm has always been worth a pound of technical skill. At the present day in every department of education, and especially in that part of it which is usually called technical, there is too great a tendency to magnify the machinery, and to ignore the spirit. If we wish our country to retain its position among the foremost countries of the world, we must recognise that neither technical skill nor scientific knowledge will avail much, unless they are combined with breadth of economic and political vision, and with depth of social feeling on the part of its citizens. If the whole aim of the present movement were the production of men who were adepts at putting on pins' heads, or of fashioning the hundredth part of a machine or manufactured product, it would be impossible for those who really thought about the matter to feel much enthusiasm for it. That the spiritual is the parent and first cause of the practical is very often forgotten by those who pride themselves on being practical. Moreover, there are higher interests which are very often neglected, and Ruskin has well said: "The great cry that rises from all our manufacturing cities, fiercer than their furnace blast, is all in very deed for this, that we manufacture everything there except men; we bleach cotton, and strengthen steel, and refine sugar, and shape pottery, but to brighten, to strengthen, to refine, or to form a single living spirit, never enters into our estimate of advantages. And all the evil to which that cry is urging our myriads can be

* Thring: "Theory and Practice of Teaching," page 79.

THE "LUKIN" LATHE.

CONSTRUCTED BY THE BRITANNIA COMPANY, ENGINEERS, COLCHESTER.

met only in one way; not by teaching or preaching, for to teach them is but to show them their misery, and to preach to them, if we do nothing more than preach, is to mock at it. It can be met only by a right undertaking on the part of all classes, of what kinds of labour are good for men, raising them and making them happy, by a determined sacrifice of such convenience, or beauty, or cheapness as is to be got only by the degradation of the workmen, and by equally determined demand for the products and results of healthy and ennobling labour."

The first necessity for the improvement of the training of those who intend to follow trades and crafts is a loftier ideal of the functions of elementary education, and chiefly in its human and ethical aspects. At the same time, the minds of the pupils should be trained to correct habits of thought, and in quickness and accuracy of perception, and their eyes and hands in those exercises which are necessary to make the instruction real. These latter should be more of the nature of laboratory work than of workshop routine—that is to say, they should all have an educative purpose, and not be mere pieces of training in manipulative dexterity. Of course a good deal of dexterity would naturally be the result of this kind of training, but it ought to be of such a nature that it would be of use in whatever trade or profession the pupils might ultimately adopt, but all attempts to convert the school into a workshop should be firmly resisted.

The actual workshop or manufactory is the proper place for trades or crafts to be learned, and if the selfish, commercial spirit which now everywhere prevails had not been allowed to warp our ideas of duty we would not have heard the cry for the necessity for improved technical education. Both the masters and the men have been to blame. The masters have used apprentices simply because their labour was cheaper than that of men, some being so unscrupulous as to have the greater part of their work done by them. The men, on the other hand, have been concerned chiefly in the keeping up of wages, and have done little or nothing to maintain the standard of workmanship. The ordinary apprentice is placed in a workshop and allowed to pick up his trade as best he can. For some time he runs messages and does odd jobs until he is able to use his tools, and gradually he makes his way to the more difficult pieces of work, wasting much time and a considerable amount of material in the process, for of real instruction there is little or none. What little he gets is by the generosity of the workmen, and it must be admitted that if he shows any attractive qualities he generally finds some one to take him by the hand. He thus acquires a certain amount of manual skill through the dull routine of his daily work, but as a rule he grows up an uninstructed man and an indifferent workman. When he has finished the years of his apprenticeship he becomes a member of his trade union, and then he claims to be paid at least as well as the majority of his fellow men. This is no exaggerated picture, as I can vouch for it from personal observation, especially in the larger industries connected with wood and iron, and it is supported by all who have had any experience of the matter. For instance, the following is

SENDING PICTURES BY TELEGRAPH.

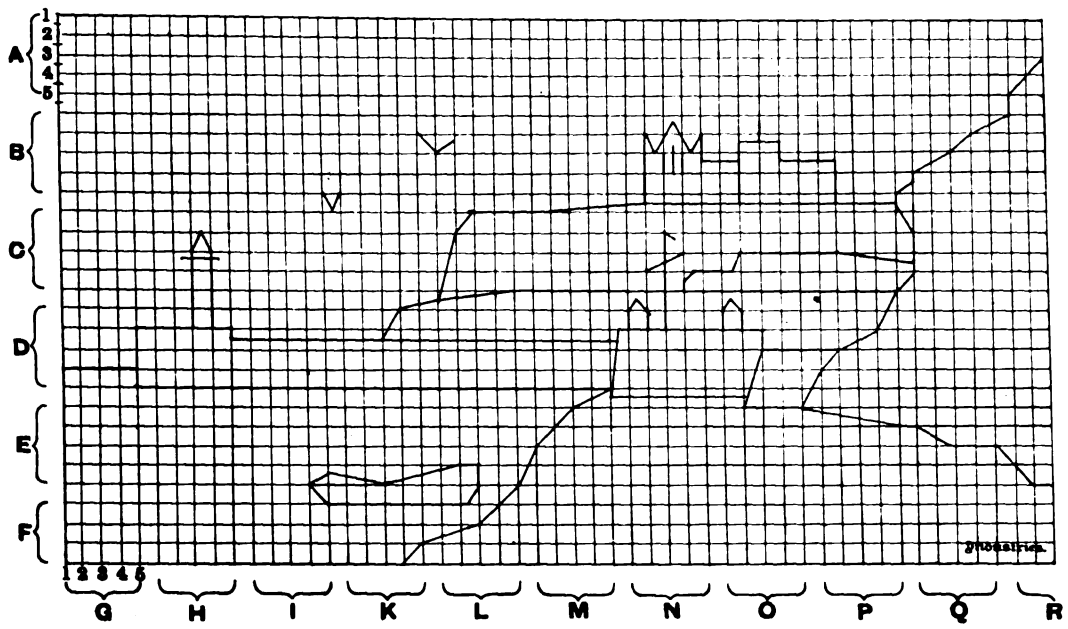

FIG. 1.—CHART FOR LOCATING THE POSITION OF LEADING POINTS IN PICTURE.

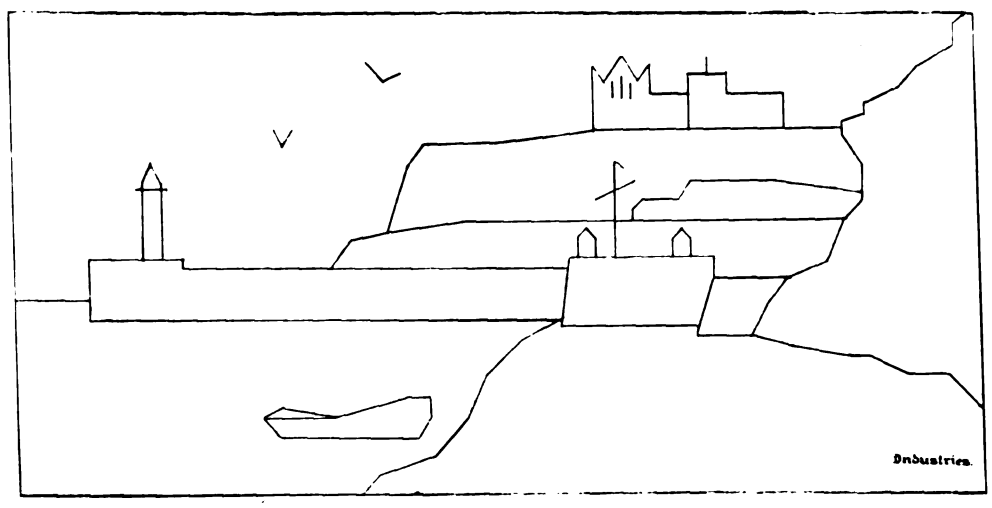

FIG. 2.—ROUGH OUTLINE OF SKETCH TAKEN FROM CHART.

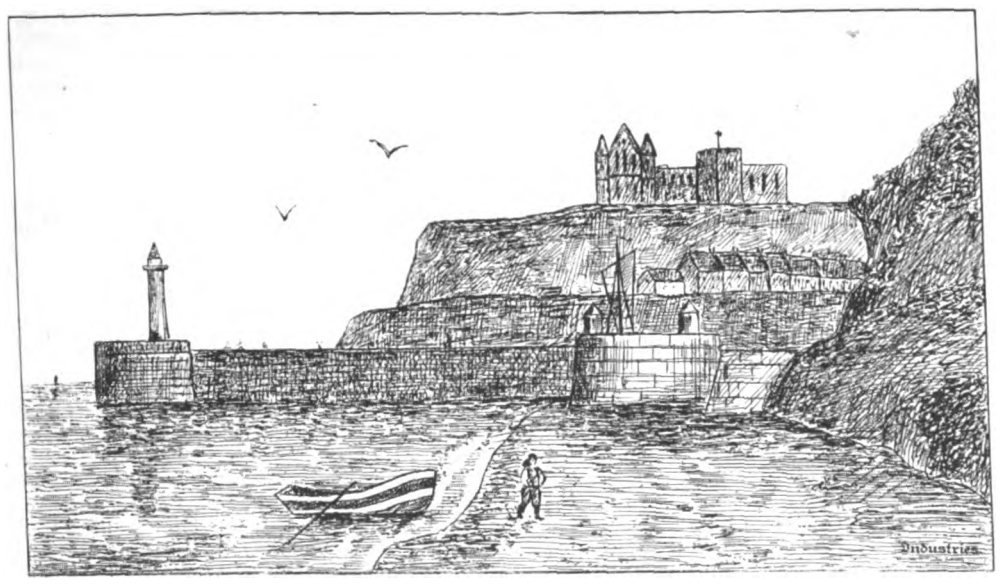

FIG. 3.—COMPLETED PICTURE SHADED IN ACCORDANCE WITH MESSAGE.

from a report by a working mechanical engineer:—"In England at the present time as soon as a boy is sent to learn a trade all mental instruction is discontinued. He conceives he has only to learn to work, and in this he is very much encouraged both at home and in the factory—at home by the indifference of his parents, in the factory by the indifference of master and foreman. In fact he is looked upon as a nuisance and in the way for the first year or two; he is set to do the most trifling jobs, and discipline is often so loose that he becomes a confirmed skulking sloven, his powers of mischief being the only faculties that evince development. The reason for work being done in a particular way is rarely put before him, and it is only when he is grown to almost man's estate that he begins to be regarded as of any value. The foreman, perhaps, notices what branch he shows most aptitude for—vice, bench, or lathe—and to this he is put and kept for the remaining term of his apprenticeship. By these means he becomes, perhaps, a fair turner or fitter, but rarely both. The neglect of mental training during his apprenticeship is so absolute that he is a worse scholar by far than when he left school. The habits of the most recent years of his life are not easily shaken off. Hence, even when he begins to be aware of his deficiencies, he is rarely to be found attending a science school. He lives and works—it may be steadily and soberly—but at the best like a mere machine. In many cases he does not know how to make the simplest calculation in relation to his work."* Moreover, it is well known that "The ever-increasing competition in production has led to the employment in many trades of children to do work of a mechanical kind requiring little skill; but whilst thus employed these young people have little opportunity of learning those parts of their trade in which skill and special knowledge are needed; and when they are grown up and seek higher wages they are dismissed to make room for other children. Numbers of young men are thus thrown upon the labour market, competent to do nothing more than children's work and to earn children's wages, and knowing no trade to which they can apply their hands."† It is thus quite evident that while in the industrial development production has been largely improved the producers have been very much neglected.

It has been frequently stated in recent years that the system of apprenticeship is practically dead, or at least is quite unsuited to the conditions of the present times. In the trades connected with engineering, apprenticeship is certainly not dead, although, like many other things, it may have lost much of its reality. The trades unions have always insisted upon it so far as they can, and so have the masters, at least in the matter of wages. What we want is not a new-fangled system of schools, which would become an intolerable burden to the community, but rather an improvement and extension of those we have, coupled with a higher sense of duty on the part of the employers and employed to those who are fitting themselves to become tradesmen. If we had proper systems of elementary and secondary education, the great majority of those engaged in trades and crafts could get all they required in properly organised evening classes during the time they were serving their apprenticeship. No one should be considered a journeyman until he has reached the age of twenty-one, however long he may have been in the workshops, although those who had been at least five years should be ranked as improvers and receive wages in proportion to their skill as workmen. A minimum of at least three years in the workshops should be required of all who were admitted as journeymen. Arrangements would thus be made which would suit the convenience of boys leaving both the elementary and the secondary schools, the latter of whom would be able to make more rapid progress than the younger boys, not only on account of their greater age, but also because of their better preliminary training.

The present Science and Art Classes, which are now so common throughout the country, would, if their methods were improved, be sufficient to meet the wants of the great majority of the apprentices, but in some cases it might be necessary to institute special classes, and these should be supported by, and be under the supervision of, the trades and crafts. At present this is done by the plumbers, coachbuilders, printers, and others, with the most marked advantages to all.

Those who were able to take advantage of the day classes of a Technical College or University would get all they required in the way of theory in these classes, but such as intended to follow the practice of the work should be expected to serve at least three years in an actual workshop or manufactory. Although trade schools are not likely to make much progress in this country, still a limited number of them would be found useful. There are a great many young men who do not propose to become tradesmen who would find it an advantage to be able to freely use the ordinary tools for wood and iron; others cannot decide what work they would like to follow, and a year or two in such a school enables them to find out their special aptitudes. Then, again, work is so subdivided in manufactories that it is very difficult to obtain a practical knowledge of anything outside the departments in which they may have been engaged, and a short time in a trades school would be of use to them in gaining a little experience in the other departments. Such schools, however, should be either self-supporting, or be kept up by those directly interested in the trades, for if once started and supported by the public rates, they would go on increasing till we had them for every trade in the country, and the tendency would be to transfer many of the functions of the workshop to them, and the whole system would break down through its complexity.

That apprenticeship, supplemented by evening classes for the theoretical parts of the work, is the proper training for tradesmen and craftsmen, is the opinion held by

* "Artisan Reports on the Paris Universal Exhibition of 1878," published by the Society of Arts, page 274.
† Magnus: "Industrial Education."

all who are well qualified to judge of the matter. It was strongly insisted upon, for instance, by Sir Benjamin Browne, at the last meeting of the British Association, and he mentioned the practice of the firm with which he is connected (R. & W. Hawthorn, Leslie, & Co.) as having given good results. He said that instead of starting new classes the partners decided to pay the fees of every apprentice who attended any evening class approved by the firm. He also advised that, when possible, apprentices should have opportunities of attending day classes for six or eight months when they were just out of their apprenticeship. In our present social and industrial organisation, the element of personal responsibility is gradually being dissolved, and in the training of apprentices it has almost disappeared. If employers of labour would look upon technical schools and colleges as arrangements which had been rendered necessary by our present rather complicated system of civilisation, and give them their material and moral support, and encourage their apprentices to take advantage of them, the problem of technical education would be solved.

(To be continued.)

SENDING PICTURES BY TELEGRAPH.

Mr. H. Rickinson, of 13, Wellington Street, Islington, London, N., is the inventor of a system of transmitting sketches by telegraph. The advantages of such a method of communication lie in its applicability in time of war to telegraphing the position of an enemy, &c. It would also be useful in tracking a criminal, for his portrait could be transmitted rapidly from place to place. The method of working will be understood from the illustrations on page 194 and the above table. The original sketch is divided up into squares by means of ordinates and abscissæ, and each square is identified by the letters which are ranged along the sides of the chart. Each of these squares is again divided into five parts, which are identified by the numbers 1, 2, 3, 4, and 5, and each such part is divided into two, and half the part is denoted by the letter j. Any point in the picture thus has two co-ordinates, as in analytical geometry, and these co-ordinates are communicated by telegraph. A broken line is, of course, identified by a number of points taken along it. When the sketch has been reproduced by joining the points constituting the lines, the details may be filled in by the aid of the descriptive words added. The diagrams and table of the telegraphic message so fully explain the method that further comment is unnecessary. It may be of interest to add that the scene depicted in the specimen illustration is a view from Whitby Harbour.

THE STRAIGHTENING OF CHIMNEY SHAFTS.

By C. Molyneux and J. M. Wood, A.M.Inst.C.E.

The deviation of a chimney shaft from the vertical is often to be traced to the settlement or giving way of the foundation in consequence of too great a load being placed upon it. In some cases it is due to the rapid rate at which the chimney has been built, whereby the mortar in the joints is unable to carry the superincumbent weight; or the chimney may have been canted from the vertical by the force of the wind whilst the mortar is still soft and yielding. There are also cases recorded in which one side of a chimney was exposed to a continuous period of wet weather, which kept the mortar soft and allowed the shaft to settle on one side.

The work of straightening a shaft is a work of considerable difficulty, besides entailing serious risks; in fact, it must be looked upon as a bold piece of engineering, and one in which the utmost caution should be used. All the conditions under which the chimney was built should be known before any work of this character is undertaken; and it will often be found advisable rather to rebuild a shaft than to attempt to straighten it. Under no circumstances should an attempt be made to restore the structure to the vertical position, by sawing out the joints, or removing courses of brickwork—*i.e.*, "cutting back," as it is technically called—unless the shell of the stalk is built solid as a whole, in one material, and is absolutely homogeneous, the brickwork or masonry being of the highest character throughout. Many existing *brick* chimneys have been successfully cut back in the hands of skilful and cautious men; but, on the other hand, many have received fatal cuts, and have either fallen under the operation or a short time afterwards, among which may be mentioned the noted Newlands Mill chimney. The cutting back of *stone* shafts is seldom attempted, there being only a few successful cases recorded. When it has been decided to straighten a chimney, the aid of a specialist or professional "chimney doctor" should be called in: for his experience and staff of workmen, &c., are essential to the successful treatment of the case.

The first operation is to determine exactly how much the shaft deviates from the vertical, and from this a careful calculation is to be made to find the necessary gap or depth of the cut. The cut should be of a wedge shape with a maximum opening at the outer circumference tapering away to nothing at the centre. Allowance has to be made for settlement, so that the chimney shall not afterwards incline in the opposite direction. When the deviation is considerable, it is usual to make several cuts—*i.e.*, at several joints; but in no case should they be close together. If the shaft deviates, as a whole, from settlement of the foundation, the cut is made as low as possible. It must be borne in mind that when once a chimney has been partly cut or sawn through, its stability depends entirely upon its own weight, all cohesion at the bed joint being destroyed; it is, therefore, advisable to keep the cuts as low down as is practicable. When a brick chimney is of considerable diameter the method sometimes adopted is to cut out either one or two courses of bricks half-way round the chimney on the side opposite to that towards which the chimney leans, and replace the same by a thinner course of brick or hard stone of wedge-shape form. In executing this operation the brickwork is cut out in segments of, say, about 2ft., and is replaced by a thinner course. The first incision is made directly opposite to the direction in which the shaft leans; the next incision is made to the right or left, and so on alternately until one half of the chimney has been cut through. As this work proceeds wedges are driven in to keep the cut open. The cutting out can be carried out from both the inside and outside at the same time by the aid of long chisels. As soon as the cut has been made half way round, and the wedges slackened, a loud report is almost invariably heard, which is caused by the breaking of the rest of the joint. The chimney begins to move, and by slight oscillations slowly settles down on the thinner inserted course. A large shaft in Prussia, 331ft. in height, was successfully cut back by this method.

The usual plan, however, now adopted is to make an incision boldly into the shaft, as above described, and insert, as the brickwork is cut away, strong steel screw-jacks, whose function is to support the superincumbent mass above as the masonry in the cut is removed. These jacks are from 7in. to 10in. in length; above and below them are placed strong wrought iron plates to distribute the load and obtain a good bearing. When the cut has been completed, and the jacks all inserted at their proper places, the next operation is to gradually and uniformly unscrew them, till the shaft has nearly regained its vertical position. The space between the jacks, and finally that occupied by them, is filled in with solid brickwork. It is usual to commence making good the cut before the chimney has quite returned to the vertical position, otherwise the slight settlement of the new work will bring the chimney in the opposite direction.

The Townsend Shaft, Glasgow, was straightened by sawing out the brick joints from the inside; no less than 12 cuts were made in the shaft, the first at a height of 41ft., and the last 326ft. from the ground line. Before this operation, the shaft was stated to be 7ft. 9in. out of the vertical: it came back in a slightly oscillating manner, and the men could tell when it was returning by the saws tightening. (See Bancroft, "On Chimneys.") A few years ago a very massive chimney, 100ft. in height, at the Royal Arsenal Gas Works, was successfully straightened. The foundation settled, and the shaft inclined 3ft. 6in. out of the vertical. Notwithstanding that calculations were made which showed that it could remain more than 3ft. out of the perpendicular without over-reaching the limit of safety, it was deemed advisable to cut it back, and this was accordingly done.

In conclusion, it may not be unnecessary to warn proprietors of chimney shafts against unscrupulous practitioners claiming to be "chimney doctors," but who are quacks and incompetent men, and yet always ready to undertake any sort of work of this description.

THE DISCOVERY OF COAL IN KENT.

It is now upwards of thirty years since Godwin Austen first pointed out the close connection which exists between the Rhenish and Belgian coal beds, and those in the midland and northern counties of England. Last week we alluded to the success which has attended the efforts of Sir Edward Watkin in this direction, which fully confirm the predictions of geologists on the presence of coal in the south of England. It is gratifying to find, not only that the predictions of the geologists have been fully borne out, but that the two or three years' work under the direction of Mr. Francis Brady, the engineer-in-chief to the South-Eastern and Tunnel Companies, should bear fruit so soon. It is, of course, too early to predict the commercial value of the discovery, but there certainly seems good grounds for believing that a genuine coal field of unknown extent has been reached in the Dover boring, and that there is no obstacle to working these deposits. The seam was struck after passing through 20ft. of clay, grits, and blackish shales, which undoubtedly belong to the coal measures, and resemble very closely the sequence which is observed in the Somersetshire coal fields. The comparative low depth of 1,180ft. at which the find was made is due to these coal measures being separated by only a few feet of intervening beds of sand, limestone, and black clay, and there being no new red marl at the Shakespeare boring. The lines of bedding in the shale are distinctly horizontal, and thus contribute to the ease with which the deposits may in future be worked. It is exceedingly interesting to note that the locality in which the coal has been found, and the absence of any considerable depth of overlying strata, coincides with the predictions of Godwin Austen and other geologists. In the paper already alluded to, he shows that the influence of the old axis of flexure on the distribution of the oolitic and cretaceous groups favours the presumption that there are no very thick series of overlying strata interposed between the coal measure series and the present surface. He placed the position of the hidden coal measures as occupying a line on the north of the Weald denudation, and conforming generally to the direction of the valley of the Thames.

IMPROVED REDUCING VALVE.

CONSTRUCTED BY MESSRS. WILLIAM REID & CO., LONDON.

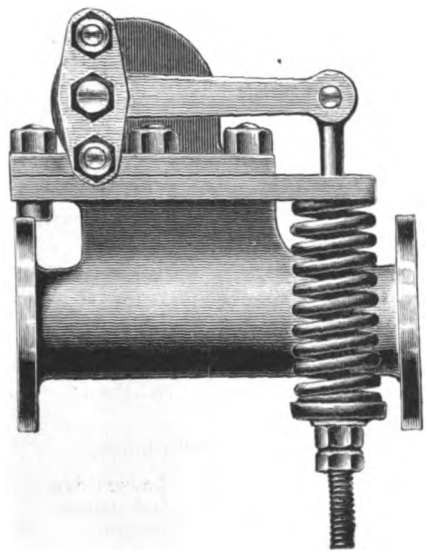

FIG. 1.—FRONT ELEVATION.

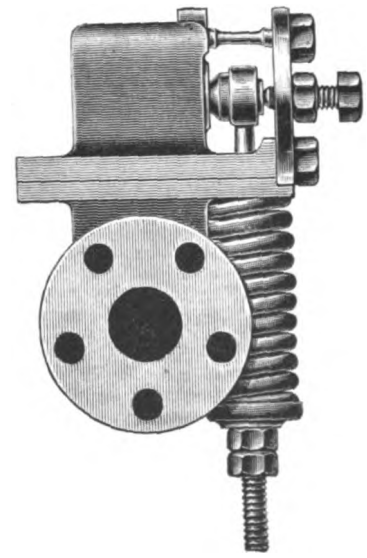

FIG. 2.—END ELEVATION.

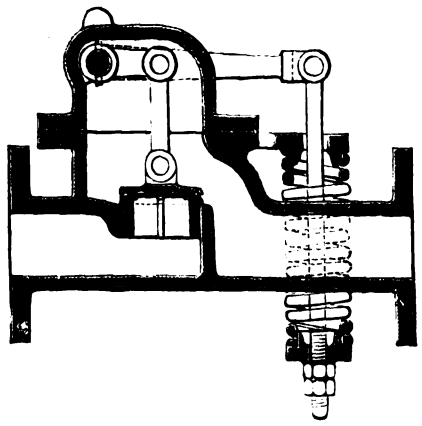

FIG. 3.—LONGITUDINAL SECTION.

There seems also reason to believe that a lower stage of coal deposits also exists somewhat west of the Boulonnais district and of equal value, which in England may occur on a line coincident with the northern chalk escarpment of the Weald denudation. Subsequent to these remarkable predictions of Godwin Austen on "The possible extension of the coal measures beneath the south-eastern part of England," the sinking of several deep wells gave geologists a further insight into the distribution of palæozoic rocks in the London area, since Devonian rocks were found immediately beneath the cretaceous group in London and near Cheshunt, and Upper Silurian shales below the gault at Ware. The British Association boring in 1872 at Battle had to be abandoned at a depth of 1,998ft. in the Oxford clay owing to the smallness of the bore. But later the coal measures were touched in Calais at 1,032ft. and at Burford, in Oxfordshire, at a depth of 1,184ft., identical, in fact, with that of last week's triumph at Dover. Characteristic coal plants were found at both of these places, but as no coal was obtained the borings were abandoned. Although coal was not found at Calais, it is worked beneath the chalk of the north of France in the Valenciennes coal field, which is known to extend 80 miles west of Valenciennes, by Douay, Bethune, and St. Omer.

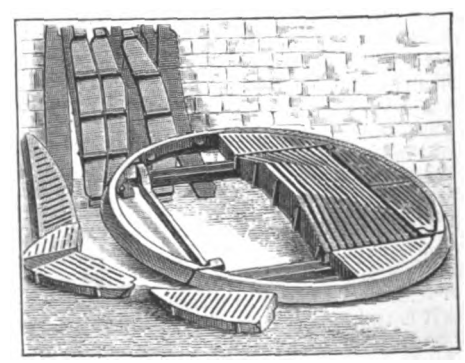
In 1877 the sinking of a well at Messrs. Meux & Co.'s brewery in the Tottenham Court Road to 1,140ft. revealed Upper Devonian rocks, and this, coupled with the finding of Silurian rocks at Ware, clearly pointed to the absence of the carboniferous series in the whole of the London district immediately north of the Thames. Since 1877 several deep wells have been sunk in the London basin, the deepest of which, at Richmond, reached the trias rocks, while at Harwich lower carboniferous beds and no coal measures were found. Mr. Whittaker, in reviewing the addition to our knowledge from these further sinkings, in a paper on the deep-seated geology of the London basin, read before the Geological Society in 1886, says: "As to the question of finding coal measures along the valley of the Thames, it seems to me that a hopeful answer is possible, or at least that a negative cannot be given, for we know not what may be hidden under the Jurassic and possibly Triassic beds that have been found, and as Upper Devonian and Lower Carboniferous rocks have already been found, it would be strange if the Upper Carboniferous had been wholly swept off." He also states that from topographical considerations, and nearness to tracts where older rocks are known to occur, Dover is well placed, as it is at no very great distance from the outcrop of the carboniferous rocks of Northern France. He further points out that it is clearly of importance to begin any fresh work at as low a level as possible, and adds: "Here, again, Dover is a good site, the lower part of the town being little above the level of the sea. The progress, therefore, of a deep boring at Dover should be watched with much interest."

Prof. Prestwich, in the discussion which followed the reading of the paper, also expressed his strong opinion that somewhere in the district between the Thames, near Chatham, and Harwich, was the spot where the coal measures might most probably be found, basing his argument from the analogy of the succession of strata between Boulogne and the Palæozoic rocks of the Boulonnais and that between the Battle boring, Chatham and Harwich. Recently at the Dover convict prison a boring for water was carried down to a considerable depth, but it had to be abandoned from the want of success in finding water. It reached a depth of 931ft., and passed through the chalk, gault, lower greensand, and Wealden deposits. The Channel Tunnel boring at St. Margaret's Bay is situated 2½ miles to the E.N.E. of the prison boring, and, we believe, passed through the same sequence of beds in the earlier days of the enterprise.

We shall await with much interest further details of the progress of the work, especially with regard to the thickness of the bed reached and the occurrence of lower-lying series. In the report of Saturday, the 15th inst., it will be seen that coal was first found in clay at 1,180ft. from the surface, but that at 1,183ft. 6in. the clay entirely disappeared and the coal recovered was clean and bright, and when tested by burning was found to possess a good bituminous character.

It is less than a month ago that we drew attention in our leader (*Industries*, Vol. VIII., page 61) to Mr. Hall's conclusions as to the duration of our coal supply, which show that we cannot safely calculate on our coal fields lasting more than 200 years at the most. There seems, however, from this discovery in Kent, and from the opinions held by geologists, which we have attempted to review, that there is a possibility of a considerable extension of our supplies of coal, which will necessarily prolong the time of England's independence in this respect.

RADIAL DRILLING MACHINE.



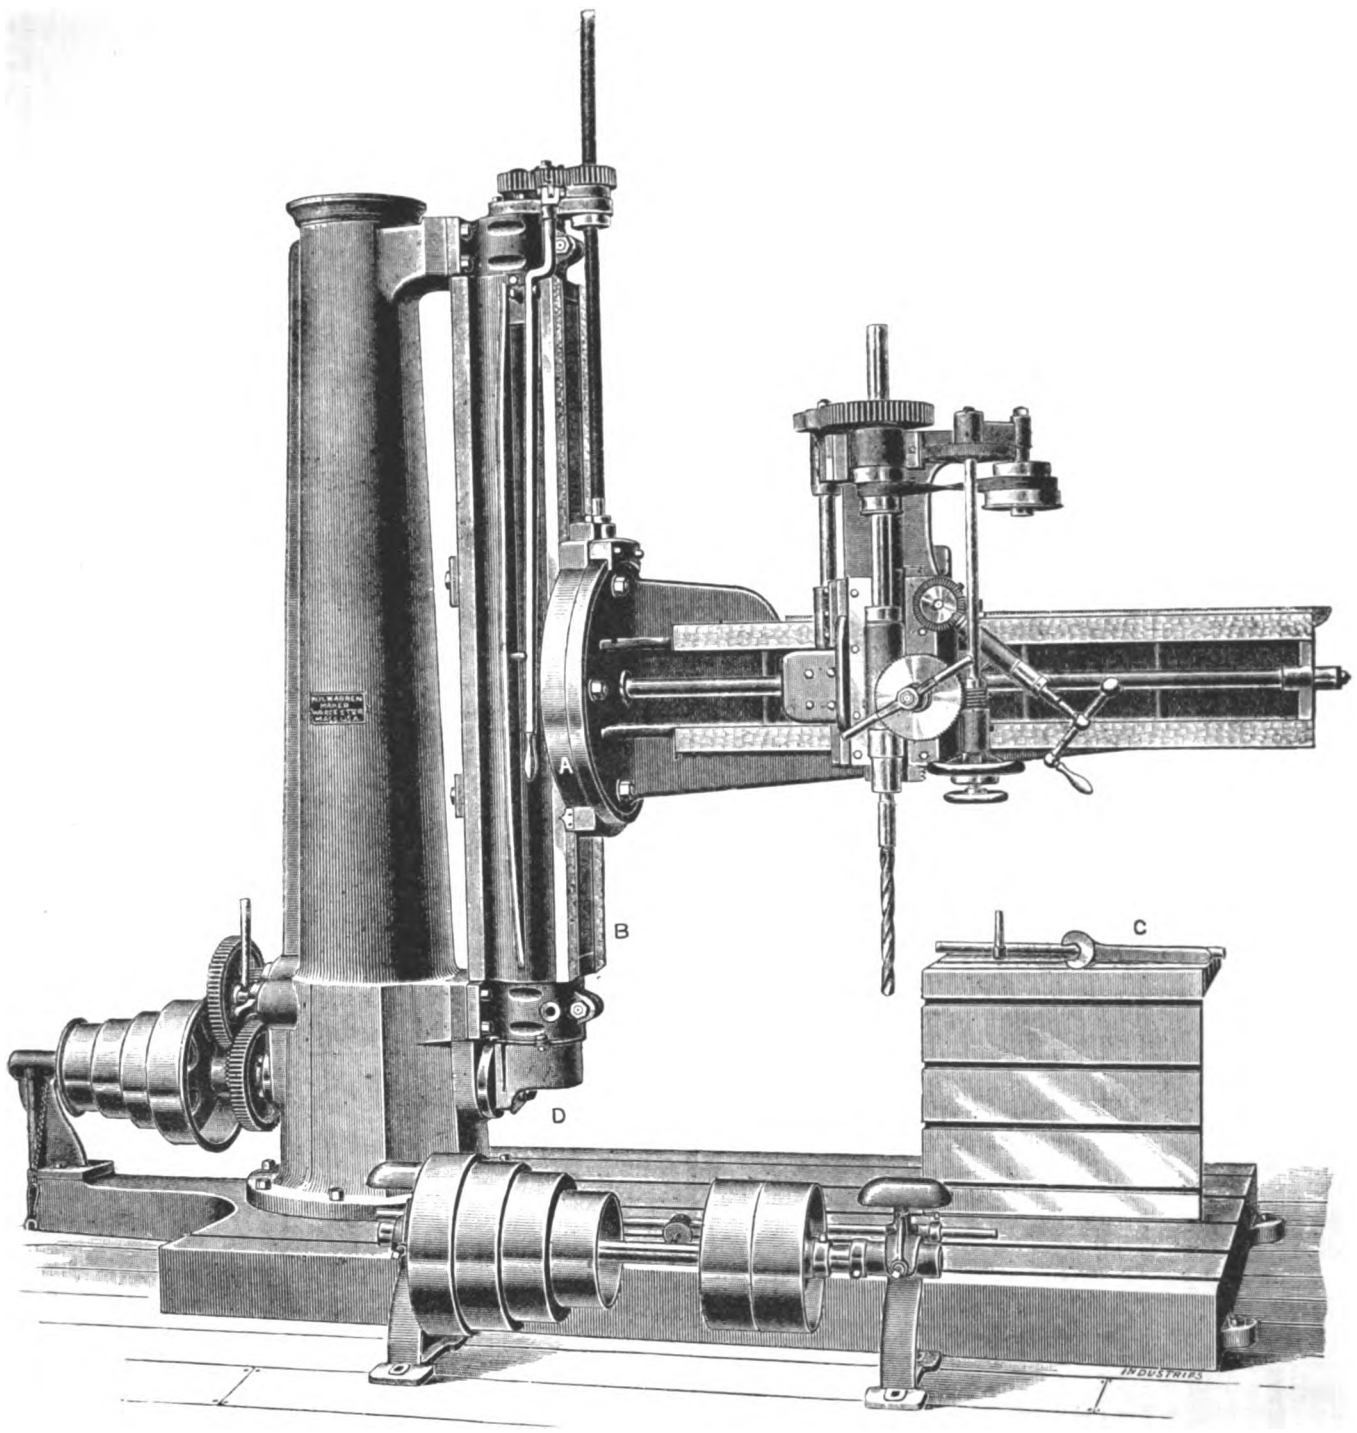
THE machine we show on the opposite page is a balanced spindle 6ft. radial drilling machine. The engravings show clearly the principal features of the machine and their arrangement, and indicate the adaptability of the machine to a wide range of work. The height of the column is 9ft. 1in., which includes the floor table, which is 6in. in height. The elevating screw, in its highest position, is 12ft. The greatest distance from the bed B to the centre of the spindle is 64in., with 13in. additional clearance in the throat D. The traverse of the head on the arm is 50in., while the arm itself radiates in a half-circle. The distance from the spindle in its highest position to the floor table is 74in., and it may be lowered to 19in. The arm has a vertical adjustment of 40in., and is raised and lowered by power. The head is moved on the arm by mechanism, so arranged with gears and rack that the operator can move it quickly, having the advantage of being over his work instead of using the screw at the end of the arm. The steel spindle is 2¼in. in diameter, has a traverse of 15in., and is driven by a 3¾in. belt on a cone having four changes—15½, 12½, 10⅞, and 9⅛in. diameter. The arm can be turned to any degree, as it swivels on a graduated shoe A, which is planed on tracks on the vertical bed B, on which it has a bearing of 29in. secured by four large bolts. The utility of having the shoe planed on the tracks is manifest when the operator desires to throw the arm over and drill in a horizontal position, as he can raise and lower the arm to accommodate the drill and counter-bore and yet retain its exact position with the work. The quick return and feed act the same in all positions. The great distance between the bearings on the vertical bed B obviates the necessity of tightening and loosening the grip bolts on surface drilling, thereby saving a large percentage of time over the ordinary radial drill. The portable table C is 27in. long, 23in. wide, and stands 24in. high. When necessary it can be readily detached and large work placed on the floor table, the extreme dimensions of which are 127in. long and 58in. wide. This table is provided with five planed slots. All the shafts are steel, and the bearings long and large. All the slides are scraped to fit. A speed of the counter-shaft of 190 drives the spindle on quickest speed 190, and on slowest with back gears nineteen revolutions per minute. The balance-weight runs on planed grooves and requires no adjustment in the positions shown. The shipping weight of the machine is 10,500lb. This and the patented 16in. and 26in. stroke traverse head shapers are specialties built by William H. Warren, of Worcester, Mass. We are indebted to our contemporary, *The Iron Age*, for the illustrations.

IMPROVED REDUCING VALVE.

WE illustrate above an improved reducing valve which is now being placed on the market by Messrs. William Reid & Co., 45, Fenchurch Street, London, E.C. It will be seen that there is no packing required and no so-called automatic parts to get out of order. The valve can be fitted easily in the engine-room, as it occupies but little space, and, as will be seen from the illustrations, its construction is extremely simple.

IMPROVED GRATE FOR VERTICAL BOILERS.

THE new form of grate which we illustrate below has been invented and is being manufactured by Mr. N. Downing, Clarence Foundry, Stockton-on-Tees. It will be seen from the figure that the central part of the grate is raised; thus there is very little fire in the middle, and



the air can thus pass through more freely and mix with the unconsumed gases as they come off from the outer layers of fuel, which are thicker. The inventor claims that the fuel is more thoroughly consumed, and that an economy of fuel is the result. The grate is made in segments, in the way indicated in the illustration, and if one part wears out before the rest, it can be easily replaced.

FOREIGN INDUSTRIES.

(From our own Correspondents.)

(FOR LATEST TELEGRAPHIC DESPATCHES SEE PAGE 201.)

PARIS, 25TH FEBRUARY, 1890.

COAL.—The market for coal continues active and buoyant in spite of the high prices prevailing. Coal which a year ago could be purchased at Rouen for 13s. a ton now sells at 27s. to 28s. There is no prospect of lower rates. The miners seem disposed to demand still higher wages. There is much efferverscence among the colliers of the St. Etienne basin. Some 2,000 have turned out on strike on some trivial pretext. It is feared that this disturbance may bring about a general strike in the locality. The miners of the North are now receiving a high rate of wages, with which, however, they do not seem to be content. The cost of production is being everywhere increased.

THE FOREIGN COAL TRADE.—The shrinkage in the imports of foreign coal is continued into the year 1890. The quantity received for consumption in the country in January amounted to 580,999 tons, against 587,012 tons in the same month of 1889. The falling off is pretty equally distributed over the trade with England, Belgium, and Germany. As a set off to the shrinkage there was a considerable increase in the purchases of foreign coke, 72,799 tons against 67,078 tons. This increase was wholly in the trade with Belgium, the German imports having fallen off heavily. The exports of French coal in the month of January amounted to 85,740 tons against 63,399 tons in 1889 and 26,375 tons in 1888.

IRON.—There is but little doing in the Paris market, and though merchants have issued circulars announcing a further rise, they find it difficult to obtain last week's prices. Business continues active in the Haute-Marne, where one manufacturer has put up his price for bars to 168s. The pig iron market of the Meurthe-et-Moselle shows some symptoms of weakness. It is reported that a large iron and steel works is about to be established at Longwy, in which Belgian and French capitalists will take part. Founders are getting more busy again. Business seems to be steadily reviving in the Ardennes. The weakness which appeared in the markets for finished iron and steel in some places at the beginning of the week has disappeared.

OSIER CULTURE.—The Société d'Agriculture of Montreuil-sur-Mer has addressed a petition to the Minister of Agriculture praying for the imposition of an import duty of 3·75fr. per hundred kilogrammes on peeled osiers, and one of 1·50fr. on the unprepared bundles. It appears from this petition that foreign competition is fast destroying the formerly important industry of osier growing in the valleys of the Caniche, the Lys, and the Aa. The imports of osiers last year amounted to 79 tons against 53 tons in 1888 and 18 tons in 1887.

PRODUCTION OF IRON IN 1889.—The official statistics of the production of iron and steel in the year 1889 have just been published. From these we learn that the make of pig of all sorts amounted to 1,722,480 tons, of which quantity 940,719 tons were produced in the Meurthe-et-Moselle. The production of finished iron amounted to 793,358 tons, and that of steel of all sorts to 529,021 tons. This is a considerable increase for all classes on the production of the previous year.

TELEPHONES IN PARIS.—The Minister of Posts and Telegraphs has decided to erect a large telephone exchange in the centre of Paris. There will be accommodation for 30,000 subscribers. This should cause a great improvement in the telephone service.

ELECTRIC LIGHT ON IRONCLADS.—The ironclad "La Hoche" has an electric light installation which is worthy of notice. There are six projectors, which are fitted with arc lamps of 70 amperes, 14 incandescent lamps of 50 c.p., 23 incandescent lamps of 32 c.p., and 350 of 10 c.p. The voltage of the current is 65. The motive power is supplied by compound engines by Messrs. Breguet, the speed being 350 revolutions per minute, and the current is generated by four Desroziers dynamos.

BERLIN, 24TH FEBRUARY, 1890.

BRESLAU INTERNATIONAL MACHINERY FAIR.—The twenty-seventh international machinery fair will this year be held at Breslau on the 9th, 10th, and 11th of June next. The necessary space has already been obtained and a large number of allotments made. Dutiable goods will be admitted and returned free if unsold. Also for such goods the railway authorities have offered to forego all charges for the return journey, provided they be sent back within four weeks of the close of the fair. Judging from the applications for space in this important international market, the meeting will be this year an exceptionally good one.

BRESLAU STRAW HAT MANUFACTURE.—Breslau is, after Dresden, the most important centre of the straw hat and bonnet trade of Germany. Breslau, indeed, takes the first place for quality of manufacture and taste in design. The number of persons employed—chiefly women and girls—in this industry is about 2,000, and the mean value of the annual production about two million marks. Besides the straw goods ladies' felt hats are manufactured to the value of about one million marks annually. The export trade in straw hats is rapidly growing. The number exported in 1889 amounted to 2,861,153 for untrimmed, and to 549,192 for trimmed goods. More than half the former were sold to French customers.

JUTE FACTORY.—A share company, with a working capital of one million marks, has been formed at Bremen, to take over and work the jute spinning and weaving factories of the firm of Vogt, Wex, & Co., at Delmenhorst. The company will be known as the "Hanseatische Jute-Spinnerei und Weberei."

LINEN YARNS.—The linen yarn market grows more active. From Trautenau we learn that buyers are dealing freely. Prices are very firm. At Bielefeld, too, the market is strong, the demand having freshened a little of late.

THE SMALL ARMS INDUSTRY.—Great activity prevails in all the small arms factories, both Government and private. The Oberndorff works in Wurtemburg are busy on an order, recently received from the Turkish Government, for 400,000 Mauser rifles and 40,000 carbines. Upwards of 115,000 rifles have already been delivered in Constantinople.

COAL IN BERLIN.—The coal and coke consumption of Berlin in 1889 amounted to 1,319,957 tons. Besides this there were consumed 678,902 tons of lignite. The use of lignite is rapidly increasing. By far the greater portion of the Berlin coal supply is derived from Upper Silesia. A small quantity of Westphalian and English coal finds its way to the capital.

PAPER PRICES. At a meeting of the Silesian paper makers the other day it was decided to advance prices 10 per cent.

PAPER EXPORTS.—The exports of German-made paper in 1889 amounted to 299,456 cwt. of wrapping and packing paper, 558,010 cwt. of printing, writing, and drawing paper, and 50,700 cwt. of wall paper. The quantities shipped to Great Britain were 109,302 cwt. of the first, 134,134 cwt. of the second, and 1,908 cwt. of the third.

LARGE GUNS.—Some time ago M. Krupp, of Essen, received an order for twenty large guns from the Spanish Government. These guns are to be used for defence at various seaports in Spain, and they each weigh about 50 tons, the bore being 30 centimetres. Five of them are now being shipped at Hamburg, where they arrived by rail from Essen. Great satisfaction has been expressed by the representatives of the Spanish Government.

PAPER PULLEYS.—The company which carry on the works of Klein, Schanzlin, & Co. are now selling pulleys which are made by hydraulic pressure from paper pulp. They claim that their frictional grip is greater than that of cast iron pulleys. Thus, the tension of the belt may be reduced, and consequently the vibration of the machinery.

VIENNA, 24TH FEBRUARY, 1890.

THE COAL MARKET.—There is no change to be noted in the coal market. The business is very animated, and prices are firm, with a tendency to advance.

THE IRON MARKET.—The animated business in all branches of the market is being followed by a raising of the prices, not only as regards pig iron, but also as regards manufactured iron of all kinds. The opinion prevails, however, that this haste to raise the prices will cause the prices to become rather uncertain. Machine manufactories are very busy, and their inability to accept orders is retarding some other enterprises. Some home capitalists are making the most of this good state of things by erecting a new machine shop near to Brünn.

ELECTRICAL ENGINEERING.—The adoption of the electric light in Austria is proceeding apace. The Empress's villa at Lainz has been lighted in this manner for three years or so, the installation having been put in by B. Egger & Co., and in a short time the summer residence of the Emperor at Iselil is to be lit in the same way. The watering places are following each other's examples in providing public installations, and in a short time all the more important ones will be lit electrically. At Carlsbad the central station will be supplied with alternate current dynamos by Hilbert, of Nürnberg. At Brünn it is probable that a fourth installation will be erected shortly. Most of the electrical firms will be represented at the forthcoming Agricultural Exhibition at Vienna. Messrs. Siemens & Halske have established a cable manufactory at Vienna. This makes the tenth large cable works in Austria-Hungary. A company is about to start a works near Gastein for the manufacture of aluminium by the same process as that used at Neuhaus in Switzerland. The steam tram company and the electric tram company at Vienna have amalgamated; by this means Vienna will possess the longest electric tram-line in Europe.

BRUSSELS, 25TH FEBRUARY, 1890.

THE COAL MARKET.—The position of the coal market remains good. There is a great deal of anxiety as to the height of the prices for coke, and there seems to be no likelihood of any abatement or fall. Several producers have sold the whole of their coke, for the whole of the year, at a price of 35fr. Coking coal is quoted at about 20-23fr., and it is quite as scarce as the coke itself. The directors of the collieries in Belgium are petitioning the Minister of Railways to maintain the special tariffs for the transport of fuel.

THE IRON MARKET.—New orders are rare at present. The position of the market will probably not alter for ten days or so, when it will be necessary to commence work on a good many contracts; then the buyers will come up more readily, unable to hold off any longer. The basis price of merchant irons remains fixed at 18fr., but many rolling mills are demanding more. Sheets are firm at 22fr., and makers of girders demand 17fr. to 18fr. Pig iron is rare, and maintains its high price.

GLASS WORKS.—The construction of the syndicate for controlling the export of window-glass to the United States is being actively carried out. The committee for considering the subject has met several times, and will soon be in a position to place a definite scheme before the meeting of glass makers. The price of window-glass remains stationary.

THE BELGIAN SOCIETY OF ENGINEERS. The Society of Belgian Engineers has just devoted two sittings to the study and discussion of the various systems of transmission of energy and to the consideration of the methods of distribution of electric light and motive power in towns. M. Anspach made a comparison between hydraulic transmission and high and low tension electric currents. He favoured the high tension (2 000 volts) system, and pointed out that the cost of distributing was much lower than by the low voltage. The dangers of high tension were, in his opinion, much exaggerated. One advantage of the high tension was that the central station could be at a distance from the distributing area, while the central station for the low tension current had to be near at hand in the middle of the town. M. Anspach did not think much of M. van Rysselberghe's hydraulic system and turbines. M. Bede combated the opinions of M. Anspach with regard to the high tension system, and M. van Rysselberghe defended his hydraulic transmission. At the second sitting of the society M. Bede explained the Popp system of transmission of energy by compressed air. The advantages would be seen in the fact that the air could not only be used for driving electric light generators, but also for ventilating and cooling purposes. M. van Rysselberghe's system had the disadvantage that nothing useful could be done with the water after it had been used.

DÜSSELDORF, 25TH FEBRUARY, 1890.

COAL.—Notwithstanding the anxiety felt respecting the attitude of the working miners—whose threat to strike early in March to enforce a claim for a 50 per cent. rise in wages is, thanks largely to the action of the English miners, likely to be carried into effect—the coal market is steady. Production has now reached its maximum. The quantity sent away daily from the Westphalian pits averages about 10,500 ten-ton truck loads. This is not only as much as the pits can turn out, but as much as the railways can deal with. The official statistics of the coal industry in 1889 show that, practically, the whole of the great increase in prices in that year has gone into the pockets of the middlemen.

A COLLIERY OWNERS' DEFENCE ASSOCIATION.—The frequency and gravity of the strikes which have of late occurred in the coal-mining districts have forced home on the colliery proprietors the necessity of combination. An association is now being formed here which will be a beginning in this direction. The principal rules of this association are to the following effect:—The contracting parties undertake to guarantee one another from loss in the case of a strike occurring in the pit of any member of the association. Before an indemnity be paid, however, the council of the association must declare the action of the men unjust, and, further, the number of men out on strike must be at least one-third of the total number employed. The amount of the indemnity is to be determined by the council. The guarantee fund is to be about one and a quarter million marks (some £62,000). Each colliery company is to contribute to this fund proportionately to the number of tons of coal it produces annually. This counter movement among the employers of labour, if taken up generally, as it is expected to be, will have important consequences to the industry of this country, and indeed of all countries.

IRON.—The iron market has developed no new feature in the week last past. In tone, however, it is somewhat firmer since the recovery in the English markets. Relatively to the past, business is quiet, particularly in crude iron, which is now much less largely dealt in. Prices remain firm, however, but the buoyancy of the market, which was so striking a feature a few weeks ago, is gone. There is a strong and steady current of business in finished iron and steel. At the meeting of the West of Germany Common Plate Makers' Association, held at Cologne on the 21st inst., it was agreed that the existing situation is, for the plate trade, exceptionally good, and the near prospect encouraging. No alteration was made in prices, which stand as follows:—Iron boiler plates, 260s.; common plates, 235s.; steel boiler plates, 225s.; and common plates, 210s. per ton.

ASSOCIATION OF IRON GALVANISERS.—A well-attended meeting of iron galvanisers was held a week ago at Cologne with a view to the formation of an association or syndicate for regulating the prices of galvanised sheets. A committee of six was appointed to draw up rules to be submitted to the next meeting called for March 10th.

LILLE, 25TH FEBRUARY, 1890.

IRON.—The iron market has an appearance of strength, but it is said that iron in quantities of considerable importance may be bought a few shillings below the official quotations. Certainly orders are not coming in so freely as formerly. The Government statistics of production in 1889 give as the output of the Nord 216,714 (1,722,480)

Digitized by Google

tons of pig iron, 310,494 (793,358) tons of finished iron, and 67,230 (529,021) tons of steel. The quantities in parentheses are the totals for the whole country.

TEXTILE MANUFACTURES.—The market for linen goods is scarcely so active as it was last week, but some falling off is usual at this season of the year. The great Paris houses are buying less. In part compensation, however, inquiries from the provinces are more numerous. Prices are well maintained. The quantity of linen piece goods sent away from Armentières in 1889 amounted to 323,286 cwt., an average of 26,940 cwt. per month. Business in the woollen goods trade of Roubaix is falling off, the summer purchases having been for the most part completed. Manufacturers are already turning their attention to the next winter season, and are getting their new patterns ready.

FLAX AND YARNS.—The last few days have been a period of great activity in the market for raw flax. Large transactions have taken place in Russian produce for forward delivery at prices favourable to buyers. Home-grown flax has been freely offered for sale, and prices are in consequence a little weaker. The demand is brisk. Yellow Courtrai has been largely dealt in. The market is quiet for tows. Business is not very active for yarns, yet the sales effected are said to be sufficient to absorb the whole of the production. The finer numbers are most sought after. The market is active for jute yarns.

AMSTERDAM, 24TH FEBRUARY, 1890.

THE PETROLEUM TRADE AT ROTTERDAM.—The Communal Council of Rotterdam has sanctioned the agreement proposed by the communal authorities for the transfer of a tract of river bank near Charlois, under Rotterdam, to the German-American Petroleum Company at Bremen, who will virtually represent the interests of the Standard Oil Company of the United States. The lease is for fifteen years, from the 1st of April next, and will be renewable for ten years at the option of the lessee as soon as it expires. The town will get sixpence per square metre per annum, the area of the land being 5½ hectares, but the town authorities are to expend some £6,000 in constructing an embankment, with landing places, &c., along the front of what will virtually become the petroleum depôt of Rotterdam. The contract has not been sanctioned without some opposition, several members of the Communal Council complaining that the terms are too low compared with those demanded for the same purposes at Antwerp, and others protesting against the right of the lessee to store naphtha and turpentine at Charlois. These objections were overruled.

SAFETY ON RAILWAYS.—A Dutch engineer is applying for patent rights throughout Europe and in the United States, for a new system of preventing railway accidents which he claims to have discovered.

PRESS MESSAGES TO THE DUTCH EAST INDIES.—The Dutch and the Dutch-Indian Governments have agreed with the Eastern Extension Telegraph Company to introduce press cablegrams between Holland and her East Indian possessions at a special reduced rate.

"COCOA-NUT BUTTER."—Much attention is now being paid to the new product called "cocoa-nut butter," prepared from the fat contained in the cocoa-nut and from other vegetable fats. This "butter" is said to be richer and more palatable even than many margarines of low grade. Nethertheless, "butter" is a misnomer, as the new product is not intended for competition with dairy butter, but exclusively for cooking purposes. At present it is not manufactured in Holland at all, but only at Mannheim, where the invention of Dr. Schlemk, at Ludwigshafen, is worked by a private factory, which in 1889 turned out about one thousand kilogrammes of "cocoa-nut butter" a day, the market value thereof being about one shilling and twopence a kilogramme. But a factory upon a somewhat larger scale is at present in course of erection at Amsterdam, and the promoters of the Dutch Vegetable Butter Company believe that their article has great possibilities in the near future. They point out that the islands of the Dutch East Indies contain an inexhaustible supply of cocoa-nut palms, and that the nuts can be obtained in great quantities at a merely nominal price. These nuts are certainly valuable, because they contain not only a large amount of fat, but are enclosed in a fibrous substance, which resembles jute, and can be manufactured into yarn. The Dutch Company will, therefore, produce and bring to market two entirely distinct articles of commerce, yet coming from the same fruit—viz., "cocoa-nut butter" and cocoa-nut yarn, the latter already known in England for some time, as it is manufactured in British India.

A DUTCH PHONOGRAPH COMPANY.—There is in course of formation a Dutch Phonograph Company, which is to take over and work the Edison patents in Holland. It is intended by the promoters, who are well-known engineers in Amsterdam, to bring the phonograph within the reach of all by means of low sale prices, and by hiring them out at a moderate rental. Competent agents will be appointed in the leading cities, who will be charged with the periodical inspection of phonographs sold or let, and from whom purchasers and hirers will be able to obtain every information.

GERMAN-DUTCH RAILWAY GOODS TARIFFS.—At an important meeting of railway managers, both German and Dutch, held at Düsseldorf, it was resolved to lower the transit rates for goods considerably, as from May 1st, both viâ Belgium and viâ Dutch routes.

COPENHAGEN, 22ND FEBRUARY, 1890.

TIMBER IN SWEDEN.—Some important sales of forests have recently taken place in Sweden, where there appears to be a tendency at present to bring large tracts of forest under the same proprietorship. The Meyer Company at Karlshamn has of late bought very extensively in Vestbo, Unnaryd, &c.; not long ago they paid away on one day 500,000kr. to various sellers of forest. At Falun the right of cutting for four lots of the Orsa forest was sold at 424,150kr., which was about 25,000kr. above the reserve put upon them.

PROJECTED CANALS.—An extension of the old Stens canal at Jonsborg, Norway, which was built in the beginning of last century, has been decided upon by the Jonsborg Corporation. The projected canal is to have a depth of 21ft., and to take a straight line from Trälen to the Obe Bay. The cost has been calculated at 355,000kr., of which it is proposed that the State shall pay one-third, and the Jonsborg Corporation the rest. A large canal is under contemplation so as to establish a connection between the Lake of Venern, Sweden, and the Kattegat, as well as with the towns of Venersborg and Uddevalla. The Venern is the largest lake in Sweden, and has hitherto only been connected with the Kattegat through the Trollhättan, with its celebrated falls. The canal is 8·16 kilometres long, 2·97 metres deep, and 1·9 metres broad. It has sixteen sluices. The new canal would be 25 kilometres long and have a depth of 7 metres. It is intended to accommodate vessels up to 3,000 tons, and the canal, if carried out, will no doubt prove of great advantage to the numerous iron works in the interior of Sweden. An annual traffic of some 100,000 tons of iron is looked upon as likely to pass through the canal, and it will also prove of importance to the timber traffic. Apart from this, it will, of course, greatly facilitate the general traffic between Venern and the Kattegat. There is a good feeling for the canal being constructed, and there seems to be fair prospects of the plan being realised.

PROPOSED LAW FOR WORKMEN.—Measures for benefiting and protecting the working man are at present under consideration, and an important Government Bill has just been introduced in the Norwegian Parliament. The measure deals with all kinds of manufactories, but not with the workshops of the artisans proper. The regulations of the measure refer to the following questions: (1) Safety and sanitary measures, &c.; (2) rules for the protection of labourers by restrictions in the ordinary freedom of contract between employers and the employed; (3) regulations for control and inspection; (4) regulations for punishments, &c. Of these various regulations the following may be worth mentioning. In order to ensure the men's safety in case of fires, all manufactories, &c., shall have the necessary number of staircases and exits, and where circumstances require it there shall be special safety arrangements. On all manufactories' chimneys above 2 metres high, and on all larger manufactories, there shall be lightning conductors. Regulations are further given with regard to appliances of safety against danger from machinery in motion, &c., and to prevent the evil effect of injurious steam, dust, &c., and about the proper ventilation, lighting, warming, and cleaning of the premises. It is left with the Government to frame rules for inspections of boilers, &c. At every place of working the men shall be able to get their food warmed and accommodation for the hands to have their food in a warm room when the weather makes this necessary. It is left with the Government to give special regulations with reference to manufactories, &c., especially injurious to health, and to give orders about the men not being allowed to take their meals or spend their off-time in such places. As to children being employed, the lowest age has been placed at twelve years, and children between twelve and fourteen years only be used on a doctor's certificate that they are suitable for such work; nor must the hours be more than 6½ hours per day. The children shall have at least half-an-hour's rest not later than 4½ hours after commencing work, and all night work is prohibited for children. Nor must their work interfere with their attending school. Children must not be employed on underground mining work nor at any dangerous occupation. Lads between fourteen and eighteen years must not work more than ten hours a day and not between the hours of nine p.m. and six a.m.

MADRID, 24TH FEBRUARY, 1890.

THE BELMEZ COAL COMPANY.—The news coming from England that a company, with £140,000 capital, has been formed in London to work some coal mines in the Belmez district, has come as a surprise to every one. There are great doubts as to the success of coal mining in that district by a company which is not powerful enough to make a railway to a shipping port on the Guadalquiver. At the present rate of carriage there is nothing to be done but a very small retail business, whilst with a special railway line for conveying coals the Gibraltar market might be supplied from the Belmez district.

SHIPBUILDING YARD AT CADIZ.—It is reported that a shipbuilding yard and docks are being commenced at Cadiz, but its prospects of completion are rather vague.

IRON AND ENGINEERING INDUSTRIES.—Representatives of all the iron works and engineering firms have met at Madrid to discuss what course they ought to take in connection with the Parliamentary inquiry going on respecting the treaties and modifications in the Custom House tariffs. So far, the advantage has been altogether on the side of the iron smelters and rolling mills, as whilst the duty on pig iron and bars, as well as on steel, has been from 20 to 35 per cent., engines, boilers, and machinery in general have only paid a nominal duty. The question now is for the parties to agree on proposals to the Government which can be supported by the iron and steel makers and by the engineering trades. It is evident that pig iron and bar iron will be much lighter taxed, whilst the duty on machinery, railway rails, and rolling stock will be rigidly imposed, although it may not be a heavy one. We may look in future to see many more boilers, steam engines, and locomotives made in the country, and English firms with specialties which are sold freely in Spain will do well to be prepared to establish branch works in the North of Spain, especially the makers of Knap and of Babcock and Wilcox boilers.

SECONDARY RAILWAYS.—The Bill pending at the Cortes for an extended system of secondary railway lines, with interest guaranteed by the Government at the rate of 5 per cent., has been withdrawn by the new Minister of Public Works. It is the third project which has suffered this fate.

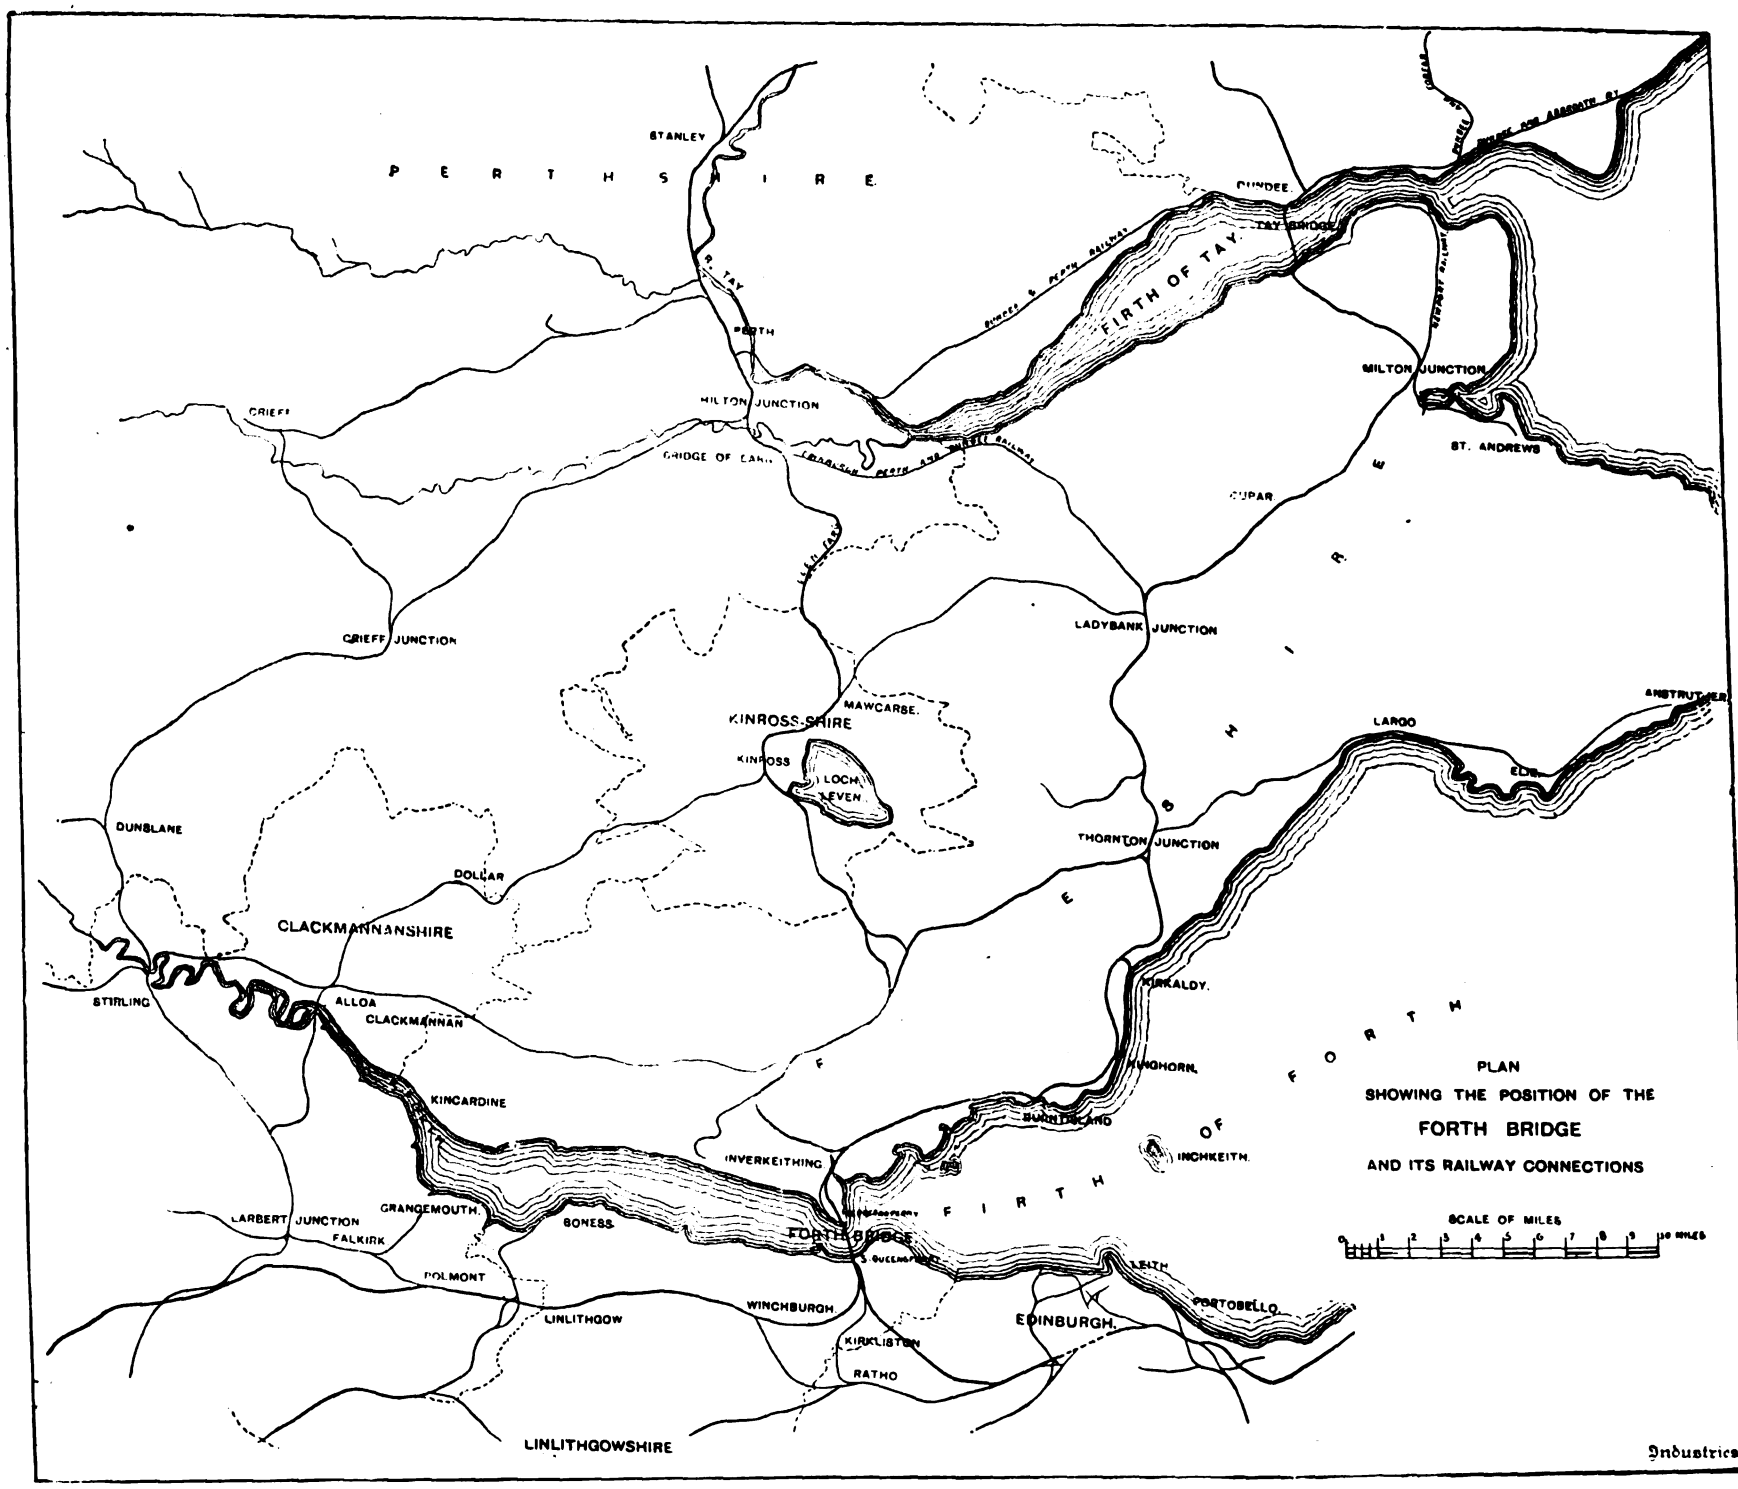
NEW YORK, 15TH FEBRUARY, 1890.

THE COAL MARKET.—There is little improvement in the anthracite trade. The production has increased slightly, and the prices are not likely to be lowered any further. The output for January was 300,000 tons less than for the corresponding month during any of the past five years. This restriction, besides being expensive to everybody connected with the trade, has had no favourable effect. A feeling is growing that something more decisive must be done. It is believed that a public association should be formed and the supply regulated and adjusted to the demand. The leading companies are agreeable to a concentrated action as far as the trade of the present year is concerned. The demand for bituminous coal is large and the movement of coke is above the average.

GLASS.—The members of the American Window Glass Importers' Association met in Springfield, Mass., on the 5th inst., and advanced the price of window glass 5 per cent. for the next five days, at the end of which time a new price list was issued and the prices advanced by 10 per cent. The demand for glass is quite remarkable. The formation of all the glass manufacturers in Pittsburg into a joint stock company is now in progress, and when this is completed all the window glass made in this country will be under the control of three large firms.

AN EDGE TOOL SYNDICATE.—At a meeting in Pittsburg on the 5th inst. the American Axe and Edge Tool Company was formed. The new corporation comprises all the axe and edge tool companies in the country. It purchased the plants outright, and will operate them under the management of their former owners. The capital stock of the new company is $4,000,000. The company will have its chief office in Pittsburg, and will have the control of 10,000 men. The object of the combination, according to the officials, is not to advance the prices, but to economise production by being enabled to purchase raw material cheaper.

A NEW STEEL BRIDGE.—The Canada Atlantic Railroad steel bridge over the St. Lawrence at Coteau Landing has been completed, and freight trains have made the initial trips. It has occupied ten months and ten days in completion. There are seventeen fixed spans, one of 139ft., two of 175ft., ten of 217ft., and four of 223ft. each, while the swing bridge covers 355ft. over the main channel.



A HARBOUR OF REFUGE.—Congressman O'Neill has presented a memorial from the Philadelphia Board of Trade, the Commercial Exchange, the Maritime Exchange, the Captains' and Vessel Owners' Association, and other commercial bodies of Philadelphia, asking for the appointment of a Board of Engineers for the purpose of making a survey and report on the construction of a harbour of refuge for deep draught vessels at the mouth of Delaware Bay. This is a question which vitally concerns the maritime interests, as the Delaware breakwater is totally inadequate for a safe harbour, as may be imagined from the numerous wrecks occurring there in the past few years. It is intended to press this matter.

NATIONAL BOARD OF TRADE.—The National Board of Trade Council has lately been holding its annual meeting in New York. The demand for a national bankruptcy law has been considered, and will be urged upon Congress, as well as the necessity for an Act to subsidise the American shipping interest for the extension of our commerce. The improvements of rivers and harbours was also considered, and it is expected that the council will appear before the Congressional Committees in order to urge their passage.

THE CHESAPEAKE AND OHIO CANAL.—The only bid for the purchase or rental of the Chesapeake and Ohio Canal was opened at Annapolis on the 5th inst. It was made by a new corporation called the Washington and Cumberland Railroad. The capital stock of this company is $2,000,000, and the line of the road is to extend from Cumberland to Washington, a distance of 240 miles, parallel with the Baltimore and Ohio Road from the coalfields to tidewater. The company proposes a lease of ninety-nine years, renewable for ever, and a railroad to be constructed on the bed or towpath of the canal. The cash value of the plan is 1¼ million dollars. The Governor of the State urged the acceptance of the bid. This canal has already cost the State of Maryland over 21 million dollars.

THE FORTH BRIDGE.

MAP OF THE ENVIRONS OF THE BRIDGE.

THE OPENING OF THE FORTH BRIDGE.

THE opening of the Forth Bridge will take place on Tuesday next, the 4th March. The occasion might be characterised fairly as a national function. H.R.H. the Prince of Wales will perform the ceremony, and will be accompanied by H.R.H. the Duke of Edinburgh and Prince George of Wales. A large number of members of both Houses of Parliament, including several members of the Cabinet, are expected to be present. H.M.S. "Devastation" will provide a guard of honour. His Royal Highness will arrive at Dalmeny House on Monday, and will be entertained to a banquet by Lord Rosebery. A special train conveying the invited guests will leave Waverley Station, Edinburgh, at 10.45 on Tuesday morning, and will arrive at 11.15 at Forth Bridge Station, where the Prince and his party will join the train. The train will cross the bridge to North Queensferry, and will proceed to Inverkeithing. Returning to North Queensferry, the party will embark on board the steamer "John Stirling" in order to have a view of the bridge from the river. They will disembark at North Queensferry, and will rejoin the train. On the arrival of the train at the centre of the connecting girder of the south span the Prince will alight, and will fix the last rivet. At the end of the south span, where it joins the approach viaduct, the bridge will be declared open. Luncheon will then be served in the Model Room of the Bridge works.

We have on so many previous occasions illustrated the structure of the bridge, and in our FORTH BRIDGE SPECIAL NUMBER, just published, have dealt with it so amply, that its characteristic features must be perfectly familiar to all our readers. We have, therefore, on the occasion of the opening, reproduced representative portraits of the men who have built it. Our single-page supplements show some of the Directors of the Forth Bridge Railway Company; Sir John Fowler, K.C.M.G., and Mr. B. Baker, F.R.S., the engineers of the bridge; and Mr. William Arrol, the principal contractor. On our four-page supplement we show Mr. Joseph Phillips, one of the partners of the firm of Messrs. Tancred, Arrol, & Co., a number of members of the engineers' staff, and a number of members of the contractors' staff, together with three representatives of firms of contractors who have supplied material for the erection of the bridge—viz., Mr. James Riley, of the Steel Company of Scotland, Glasgow; Mr. J. H. Ziegler, of the Clyde Rivet Company, Glasgow, and Mr. J. Fyfe, granite merchant, Aberdeen. It has been impossible for us to include, as we should have wished to have done, in this representation many more of those who have taken a prominent part in the labour connected with the erection of the bridge.

Above we give an outline map of the neighbourhood of the Forth Bridge, showing the railway systems which will be benefited by its construction.

On page 204 we show a number of designs for the bridge. Those in Figs. 1, 2, and 3 were drawn up in 1810; that in Figs. 4 and 5 is Sir Thomas Bouch's design, which was given up after the fall of the Tay Bridge in 1879; that in Figs. 6 and 7 was the preliminary design of the present engineers; and that in Figs. 8 and 9 is that of the present structure.

ANOTHER PROPOSED THAMES TUNNEL.—A number of public bodies and private firms petitioned the London County Council, on Tuesday last, asking them to favour some scheme for the construction of a tunnel under the Thames at Millwall. The proposition was discussed at some length, for it was felt that the means of communication between the north and south sides of the river at the East End of London were ridiculously inadequate. Other methods of communication were suggested by some of the County Councillors. The consideration of the subject was adjourned for a short time, in order to allow the members to inspect the locality.

Notices of Meetings.

SOCIETY OF ENGINEERS.—Monday, March 3rd. Paper on "The Application of Water Pressure to Machine Tools and Appliances," by Mr. Ralph Hart Tweddell, M.Inst.C.E.

INSTITUTE OF MARINE ENGINEERS.—Tuesday, March 4th, at 7.30 p.m. Paper on "Friction of Screw Propelling Engines," by Mr. W. J. N. Brett.

INSTITUTION OF CIVIL ENGINEERS.—Ordinary meeting, Tuesday, March 4th, at 8 p.m. Papers to be read: "The Hawksbury Bridge, New South Wales," by C. O. Burge, M.Inst.C.E.; "The Erection of the Dufferin Bridge over the Ganges at Benares," by F. T. G. Walton, C.I.E., M.Inst.C.E.; "The New Blackfriars Bridge on the London, Chatham, and Dover Railway," by G. E. W. Cruttwell, M.Inst.C.E. Students' meeting, Friday, March 7th, at 7.30 p.m. Paper to be read: "Telephonic Switching," by C. H. Wordingham, A.K.C., Stud.Inst.C.E.

PHYSICAL SOCIETY.—Friday, March 7th. On "Bertrand's Refractometer," by Professor S. P. Thompson.

ROYAL INSTITUTION OF GREAT BRITAIN.—Friday, March 7th, at 9 p.m. Francis Gotch, Esq., Hon. M.A. Oxon, B.A., B.Sc., on "Electrical Relations of the Brain and Spinal Cord."

PRICES CURRENT, 26TH FEBRUARY, 1890.

Quotations at per ton, unless otherwise specified.

" Australian	89	17	6	"	90	7	6
" English Ingots	95	10	0	"	.....		

Messrs. Carrick & Brockbank, Manchester, report as follows:—

COPPER: There has been a very irregular market in Chili bars during the past week. Although stocks are reported as steadily decreasing, the prices quoted on the 19th—viz., £47 15s. to £48 2s. 6d.—have not been maintained, values having given way in sympathy with the relapse in the pig iron market, and owing to the absence of speculative buying. On the 21st prices dropped as low as £46 10s. to £47, but there is now a somewhat steadier feeling at improving prices, quotations to-day being £47 to £47 7s. 6d. Manufactured is easier at £63 sheets, £67 bottoms.

TIN: A very small business has taken place in tin, and prices are weaker. Heavy arrivals, and absence of demand, have brought values down. To-day's quotations are £89 17s. 6d. to £90 5s., with quiet business.

LEAD: A better feeling prevailed in lead towards the end of last week, owing principally to purchases on German account. Quotations for foreign on the 20th were £13 10s. to £13 15s., but prices to-day are somewhat easier—viz., £13 to £13 5s.

SPELTER has fluctuated in price, and is still unsettled. The demand is small and irregular, but the stocks are small, and the price on the Continent is higher than in England. Galvanisers are very slack, and this makes the market very flat, so that prices are unsettled.

CHEMICALS.

		£	s.	d.		£	s.	d.

Tartar, Cream of	cwt.	5	12	6	—	.....		
Zinc Sulphate	ton	7	10	0	—	.....		

Messrs. S. W. Royse & Co., Manchester, report as follows:—

CHEMICALS.—We have to record another rather quiet week as far as new business is concerned, but prices are firm all round, manufacturers having plenty of orders in hand. Caustic soda is in short supply for prompt delivery, and soda ash also is very scarce. Bleaching powder is, however, quiet. There is a steady demand for alum and sulphate of alumina. Sulphate of ammonia remains steady, but little doing. Benzoles are unchanged. Carbolic acids seem to have found a level for the present.

FOREIGN TELEGRAPHIC ADVICES.

(From our own Correspondents.)

PARIS, Feb. 27.—*Iron.*—The tone of the market here is weaker. Bars are being offered at 160s. and joists at 164s. Reports from provinces good. Haute Marne prices firm. Demand for wire brisk; makers sold for three months ahead. Bright No. 19, 184s. to 188s.; annealed, 188s. to 192s. Nord business moderately active, and prices firm; plates, 200s. for common. Ardennes market quiet but strong.

Metals.—The metal market continues its downward course. Copper is giving way more rapidly, the efforts of speculators to sustain the market having become fruitless. Chili bars, £53 at Havre; best selected, £57 15s. Tin is steadily declining: Banca, £101; Straits, £98. Lead is firm at £13 Paris. Spelter is again lower: Silesian, £24 Havre. But there are signs of a recovery in the market for zinc.

BERLIN, Feb. 27.—*Bourse.*—The uncertainty of the industrial situation arising out of the labour movement now in progress shows itself more and more clearly in the business of the Bourse. Industrial securities fluctuate violently; but the general tendency is downward. Collieries are again lower, and iron and steel works are receding a little.

Iron.—Business in the iron market is moderately active. The recent advance in prices is firmly maintained. Silesian bars are quoted 210s. a ton. As much as 212s. 6d. has been paid. There is a moderately strong demand for joists and sheets.

Metals.—Business in the metal market continues slack, buyers holding aloof in expectation of lower prices. Copper is unchanged at £59 10s. to £60 for Mansfeld refined and £57 to £59 for English brands. The downward movement in tin has made further progress; Banca, £101 to £103. Lead is again lower; Clausthol refined, £15 10s. to £16. Spelter has had a sharp drop. Silesian ordinary, £24 10s. to £25.

BRESLAU, Feb. 27.—*Iron.*—The market continues animated and buoyant. One firm quotes bars 1s. a ton above the syndicate minimum of 210s. for quick delivery. All finished iron and steel works, however, book full for four and five months forward. Pig iron active; prices unaltered. Founders are more busy. Export orders numerous.

Metals.—The efforts of "bear" speculators on the London and Paris markets, though felt in Berlin, has had no effect here, where the situation is better understood. Prices show no tendency to weakness. The W.H. brand of spelter is out of the market for the present, and Hohenlohe produce is hard to find at £23 10s. Ordinary sorts firm at last week's prices. Lead, after exhibiting symptoms of weakness, is firm again.

DÜSSELDORF, Feb. 27.—*Coal.*—The market continues extremely active at the prices quoted last week. The threatening attitude of the miners causes great anxiety, and seriously retards the development of trade in every kind of manufacturing industry. It seems now tolerably certain that a strike will be declared early next month.

Iron.—For some sorts of pig iron prices have receded a little. Rhenish-Westphalian and Siegen forge may be bought, the former at 92s., the latter at 93s., and foundry No. 1 is quoted 98s. to 100s. Business is fairly active in finished iron and steel, but there is a noticeable absence of buoyancy in the market. Prices are firmly maintained; the advanced rates for wire are readily paid. Foreign orders for bars and hoops are coming to hand more freely.

The Proposed Berlin Exhibition.—The North-West group of iron and steel manufacturers, an association which includes nearly all the ironmasters and engineering firms of the Lower Rhenish and Westphalian districts, have in meeting assembled unanimously condemned the project for holding a great industrial exhibition in Berlin. The scheme is, therefore, likely to fall to the ground.

CHARLEROI, Feb. 27.—*Coal.*—The market having settled down to something like a regular level of prices, business is resuming its accustomed course. Buyers are beginning to operate for future delivery—a sign of returning confidence. The outlook is, however, still clouded by fears of further labour disturbances. The federated unions of the four coal fields of Belgium have agreed to send an ultimatum to the colliery proprietors on March 1st, to reduce the hours of labour to eight a day.

Iron.—The demand for iron is a little brisker, and there is reason to believe that trade is reviving. But the current of business is yet by no means strong. Prices are, however, firmly maintained. Bars No. 2 are quoted 152s.; angles, 152s.; joists, 148s.; and No. 2 plates, 176s. a ton. The price of these plates was in our last week's report given in francs by mistake, namely, 220fr. = 176s. per English ton.

GHENT, Feb. 27.—*Flax and Yarns.*—Dealings in Russian flax are now on a smaller scale than they were a week ago. Prices are weak. The market is well supplied with home-grown flax, the demand for which is increasing. French buyers are operating largely. The market is firm for linen and tow yarns, for which there is a steady, but not strong demand.

WE have received two of the series of fire brigade handbooks which are being published by Messrs. Shand, Mason, & Co., London. One is called "Fire Brigade Drills, with Hints on Management," and is well adapted for the use of superintendents of volunteer and other fire brigades. The other is called "Rules and Regulations for Volunteer and other Fire Brigades," and is full of useful hints and suggestions to both officers and men.

MR A. E. W. GWYN, 3, Ducksfoot Lane, Cannon Street, London, E.C., has sent us his illustrated catalogue. This catalogue is a polyglot in English, French, and Spanish, and contains full descriptions of the various machines and apparatus supplied by Mr. Gwyn, including steam cranes, excavators, dredgers, diving plant, pumps, &c.

WE have received catalogues of electric light fittings, switches, and Ayrton and Perry spring instruments from the Acme Electric Works.

MESSRS. BURKE & CO. have sent us a bound illustrated price list of their electric bell fittings, electric light fittings, and larger electrical plant.

HOME INDUSTRIES.

LONDON 27th February, 1890.

The Money Market.—The reduction of the Bank rate has had much less influence than could have been expected. For one thing, the outside market has been decidedly short of money, and so rates were kept pretty well in touch with the official minimum. As bills have apparently been left in the background until the Bank directors submitted to the pressure of the mercantile community, the active business which has been doing in discounts, shows how greatly the general business of the country required relief from the tension in the money market. The Stock Exchange has not benefited as it expected from the fall in money. On Tuesday, when a new account opened, there certainly was a slight revival, but the advance must be maintained and prolonged before the effects of the recent depression can be removed. Fears of trouble among the coal miners keep the stocks of the mineral carrying railways under a cloud, and counteract any tendency there might otherwise be towards buoyancy. American railways show a disposition to revive, but they cannot be said to be in great favour. Canadian railways are an uncertain market, with a turn towards better prices. The foreign department is quite lifeless in sympathy with the Continental Bourses. Argentine securities, after a sharp collapse, have picked up again, although the premium on gold at Buenos Ayres is again growing. Little interest is evinced in mining shares, and the miscellaneous market is subject to spasmodic jerks in individual securities without much to cause. The nitrate group is lifeless.

Companies.—The following companies have been registered since our last report: Pittsburgh Consolidated Gold Mines, Ld., with a capital of £80,000; A. G. Scott & Co., Ld., with a capital of £10,000, to carry on the business of tin box and canister makers; The Temescal Tin District, Ld., with a capital of £350,000, to acquire tin, gold, silver, or copper or other mines in California; Lynx Creek Gold and Land Co., Ld., with a capital of £47,500, to acquire certain mines in California; The Dutch Guayana Exploration Syndicate, Ld., with a capital of £6,000, to acquire lands and mines; Woodruff & Co., Ld., with a capital of £4,000, to acquire machinery and plant for making block fuel; East Pontop Coal Co., Ld., with a capital of £24,000; John Whittaker & Sons, Ld., with a capital of £10,000, to acquire cotton mills at Padiham; Henry Bannerman & Sons, Ld., with a capital of £300,000, to carry on the business of cotton spinners, &c.; The Howden Clough Colliery, Ld., with a capital of £30,000; P. & W. Maclellan, Ld., with a capital of £300,000, to carry on the business of engineers, metal merchants, &c.; The Hendre Gold Mining Co., Ld., with a capital of £60,000; Sugden, Keighley, & Co., Ld., with a capital of £60,000, to carry on the business of worsted spinners; The Pilcomago Syndicate, Ld., with a capital of £4,000, for the purpose of establishing a route for Bolivian produce to the Paraguay River; The Manchester Steel Co., with a capital of £50,000; The Anglo-Columbian Development and Exploration Co., Ld., with a capital of £100,000; Hatton, Sons, & Co., Ld., with a capital of £80,000, to carry on the business of ironmasters, &c.; Poole & White, Ld., with a capital of £20,000, to carry on the business of electric lighting; Criccieth Pier and Harbour Co., Ld., with a capital of £30,000; The Driggs-Schroeder Ordnance, Ld., with a capital of £350,000.

The Late Dock Strikes.—The results of the late dock strikes are continue to show themselves in the reports of the half-yearly meetings of the shipping companies. On Tuesday the General Steam Navigation Company of London reported that they had lost not only £22,000 gross profits referred to in the accounts, but also an amount equal to a 20 per cent. dividend. Mr. Tritton, the Chairman, said that if another similar strike occurred their ships would be transferred to other ports in order to follow the departing trade.

The Southern Railways.—For some time rumours have been afloat of an approaching combination in the working arrangements of the South-Eastern and London, Chatham, and Dover Railways. Mr. Stevens, the secretary of the former railway, however, states that the question has not been considered by the Board of Directors, nor has it even been brought before their notice.

Engineering.—The Government of India have just published a report on agricultural implements and machinery. Among other recommendations we notice one on the hand-pumps made by Messrs. Hayward, Tyler, & Co., Whitecross Street. These pumps are reported to be easily adapted for both deep and shallow wells, and to be free from objections common to some pumps.

Tenders Wanted.—The Portuguese official *Gazette* of the 15th inst. invites fresh tenders for the harbour works to be executed at Povoa do Varzim, which tenders will be opened on the 15th of March at the Department of Public Works at Lisbon. Documents showing the nature of the works, &c., may be inspected at the Commercial Department of the Foreign Office.

Imports of Fresh Meat.—The quantity of beef received from abroad during January was 125,293 cwt., against 93,150 cwt., 120,590 cwt. having been consigned *viâ* the Atlantic ports of the United States against 87,371 cwt. The imports of mutton were 127,035 cwt., as compared with 59,427 cwt. for the same month of last year. The above total includes 51,304 cwt. from New Zealand, against 32,137 cwt.; 13,264 cwt. from New South Wales, against 5,400 cwt.; 30,037 cwt. from the Argentine Republic, against 10,660 cwt.; 15,112 cwt. from Germany, against nil; and 8,926 cwt. from Holland, against 10,975 cwt. The imports of pork were 7,448 cwt., against 27,275 cwt., Holland supplying 4,049 cwt., against 22,350 cwt.

A Miners' Life Preserver.—By an inrush of water into a colliery at Pontypridd, in April, 1877, five miners were imprisoned for ten days without food, but were ultimately released by the rescuers holing through a wall of coal. The circumstance led Mr. A. Upward, of 150, Holland Road, Kensington, to invent an apparatus for ascertaining the contiguity of either water or gas to workings, and others for passing food to imprisoned miners and for rescuing them. The apparatus for ascertaining the state of a mine as regards approaching danger is firmly held to the face of the coal by means of struts and a piece of timber fixed vertically to the rear between the roof and the floor of a mine. It consists of a chamber fitted with a slide valve, which can be opened and closed at pleasure. Through a stuffing box in the chamber on the working side passes a boring tool, with which the miner drills a hole in the coal to the distance inwards to which he intends to work. Assuming this to be, say, 8ft., when he has reached that distance he withdraws the boring tool, and if neither gas nor water has made its appearance he knows that he can safely work so far in. Should he tap water or gas during the boring there would be an inrush of the one or the other into the chamber of the apparatus, and its presence would be indicated by a pressure gauge. The boring tool would then be withdrawn as far as the stuffing box, the slide valve would be closed in front of it, and steps would be taken to insure safety in the workings.

MANCHESTER, 27th February, 1890.

The Engineering Trades.—There is a perceptible lull in the demand for engineering work, but it is not expected to be more than a temporary one. Prospects of foreign work are encouraging, and engineers are not sorry for the present slackening, as it gives them time to get some of the more pressing work out of hand. Boiler makers are very actively engaged, and have no difficulty in finding a sufficiency of new business. Locomotive builders are also fully employed, and, generally, the makers of engines and gearing of all kinds are well off for work. Machine tool makers do not generally experience any great falling off in demand, although statements to that effect have been made. So far as the Manchester district is concerned, makers have plenty of orders offered. In some cases the long time wanted to complete the orders rather checks the conclusion of business, but otherwise tool makers have little cause to complain. Textile machinists are working at full pressure, and have large orders in hand. In some cases, prices have been largely raised without checking the demand, and, although it is true that at present few large new mills are being erected in this country, a continuance of the present prosperity of spinners will undoubtedly lead to a further development. Loom makers continue to be fairly busy without experiencing any great pressure. In the trades connected with copper goods, there is not quite the volume of business going on that there was, although there is not much ground for complaint at present.

Baking Machinery.—The Secretary of State for War has adopted the latest patent steam oven of Mr. James Johnston, C.E., 10, Balloon Street, Manchester, and has placed with him an order for four ovens for the new bakery at Woolwich.

Boiler Insurance.—The thirty-first annual meeting of the Boiler Insurance and Steam Power Company, Limited, was held a few days ago, when the report presented was of a very gratifying nature. The premium income has increased considerably, being £63,168, as against £57,941 in 1888, and £55,604 in 1887. During last year the Company took over the business offices and staff of the Staffordshire Boiler and Engine Insurance Company. It may also be mentioned that this Company has recently concluded a transfer of the business offices and staff of the South Wales and Monmouthshire Boiler Insurance Company. To many, a satisfactory feature of the report is the wiping out entirely of the £50,000 balance of purchase account. The clearing away of this item has been accomplished by issuing 7,000 shares at a premium of £5 per share, thus realising £35,000, and by adding to this the sum of £15,000 standing to credit of reserve fund, together producing the required total of £50,000. This amount has been invested in first-class securities, thus considerably strengthening the financial position of the Company. A special vote of thanks was passed to the chief engineer in recognition of the satisfactory results achieved during the sixteen months of his management, as also to the secretary and the staff of the Company.

Rapid Mill Building.—Messrs. Barlow & Jones, Limited, of Bolton, have just erected a new mill to contain 63,000 mule spindles, which has been remarkably quickly erected. The first brick was laid on the 31st May last, the machinery is now going in, and cotton will be spun during the month of March. It is a good type of a modern cotton mill, the boilers having been made by Messrs. W. & J. Yates, of Blackburn, and the engines by Messrs. John Musgrave & Sons, Limited, of Bolton. The latter are a fine specimen of the horizontal compound mill engines made by the firm, and were adopted by Messrs. Barlow & Jones after a long experience of other engines of the same makers. The spinning machinery is mainly by Messrs. Platt Brothers & Co., Limited, of Oldham.

Road Parcel Post.—The postal authorities are organising a system of road carriage and delivery of parcels by coaches between Manchester and Liverpool. They are erecting a number of light vans or coaches, which are to make the journey to or from either town to the other during the night. This movement has had its rise in the rates charged by the railway companies for the carriage of parcels, which the authorities think excessive.

Steaming Weaving Sheds.—The Home Secretary has decided to entrust the administration of the Act of last year, dealing with the above subject, to Mr. E. H. Osborn, one of the present factory inspectors. He has had a large experience of the subject, and is entrusted with full control in the counties of Lancashire, Cheshire, and Yorkshire. He is empowered to report directly to the chief inspector in London, so that he is, practically, head of a new department.

GLASGOW, 27th February, 1890.

Pipe-founding.—It is rumoured that a syndicate is about to be formed for the purpose of amalgamating the pipefounding businesses in the neighbourhood of Glasgow. The firms of Messrs. Andrew & James Stewart, Messrs. A. Y. Stewart & Co., and other pipe founders are mentioned in connection with the project, and Mr. William Arrol is said to be also interested. The capital of the proposed concern will, it is understood, amount to £750,000.

Scottish Railways.—The engineers appointed by the Corporation of Edinburgh (Sir John Fowler and Mr. B. Baker) to report upon the proposed underground railway in Edinburgh, promoted by the Caledonian Railway Company, have reported to the effect that they are of opinion that the vibration of the trains, should the proposed railway be carried under the south side of Prince's Street, would be highly prejudicial. Of the Scottish Railway Bills which have been announced for procedure in Parliament this session, the West Highland Railway Bill has passed the Examiner of the House of Lords; the Partick, Hillhead, and Maryhill Gas and Electricity Bill, and the Cathcart District Railway Bill, have passed the Examiner of the House of Commons; while the North British and South-Western Railway Amalgamation Bill has been found not to comply with the standing orders in respect of efficiency in the published notices.

Shipbuilding.—There is still a dearth of fresh orders. Messrs. Wm. Simons & Co., Renfrew, have contracted with the Mersey Harbour Board to supply them with a set of powerful sand pumps to be fitted to a steam hopper barge, one of the fleet of these vessels which Messrs. Simons & Co. have built for the Mersey. The sand pumps will be employed in cutting a deep channel through the Mersey Harbour bar.—Mr. James H. Hutchison, who has been for some time manager to Messrs. Russell & Co., Port Glasgow, has been appointed manager of the shipbuilding works of Messsrs. McMillan & Sons, Dumbarton, which firm is to be carried on in future as a limited liability company.—Mr. M'Gowan, manager to Messrs. John Reid & Co., Port Glasgow, has been appointed assistant manager to Sir William Armstrong, Mitchell, & Co.

Pig Iron.—The iron market has been further depressed this week, and very large sales were made, especially last Friday and Monday, when the impression went abroad that there would be no strike in the Durham district such as had been expected during the previous week. The prolonged lull in the demand leads people to wonder what is to be done with the additional 700,000 or 800,000 tons which we now make in this country, compared with about this time last year. The increasing production in America attracts also a good deal of attention, as it largely supplies some of the demand which otherwise would come here. Prices of makers' iron here are extremely irregular; hardly any is asked for, and very little for sale.

Clyde Firms and Limited Liability.—The capital for Messrs. P. & W. Maclellan, Limited, of Clutha Iron Works, Glasgow, has been subscribed for three times over The conversion of this well-known engineering business into a limited liability company is only one of several such changes now being effected and under contemplation in connection with Clyde firms. The old-established shipbuilding business, carried on in the dockyard, Dumbarton, by the McMillan family, is being reconstituted as a limited liability company, and the well-known shipbuilding and engineering business of Messrs. James and George Thomson, Clydebank, will, we understand, shortly undergo a similar change. Others firms are rumoured to have the same step under consideration, and it would seem as if strictly private co-partnery in any business of more than moderate dimensions was quite a thing of the past.

The Railway Rates Inquiry.—An inquiry regarding the schedules lodged by the Scottish railway companies with the Board of Trade will be held in Edinburgh on the 17th March and following days. Lord Balfour of Burleigh and Mr. Courtenay Boyle propose to hold a preliminary meeting with such representatives of the railway companies and objectors as choose to attend on Monday, the 3rd. The object of this meeting is to give information on matters connected with the procedure to be adopted at the inquiry, and to make such arrangements as will secure that all the important interests concerned shall have as full an opportunity as will be possible for expressing their views without

Digitized by Google

undue multiplication of evidence. The time which can be alloted to the inquiry in Edinburgh is necessarily limited, and without careful arrangement and organisation it will not be possible to utilise it to the best advantage. This meeting will take place within the Council Chamber, at 12 o'clock on Monday, March 3rd.

(From our own Correspondents.)

LIVERPOOL, 26th February, 1890.

Dock Labour Agitation.—The men at the docks are still in a very unsettled state, and although many of them are very anxious to remain at work at the present pay and under the same conditions without complaint, they are disturbed by the local agents of the Dock Labourers' Union. Instructions have come from headquarters that all men belonging to the Union and seeking employment must wear a circular metallic badge provided by the society. This has been objected to by many members, but after March 3rd the wearing of it is to be compulsory. The Liverpool Employers' Labour Association have recently held a meeting, and are fully prepared for the advent of any strike, and, if necessary, men will be drafted from other ports.

The Liverpool Shipping Trade.—The trade of the port has greatly improved within the last few months, and the strongest evidence of this is in the reports of the directors of the various shipping companies, most of which are very satisfactory, and recommend the payment of substantial dividends. In the passenger traffic to and from New York there has not been much of an increase in the number of saloon passengers, the greater number having been taken by the North German Lloyd steamers. Last year the number of saloon passengers from America landed in Liverpool was 27,000, while 30,500 went south by way of the North German Lloyd steamers. Of the saloon passengers landed in Liverpool last year 12,000 were carried by the Cunard Company.

SHEFFIELD, 26th February, 1890.

Coal.—At present no attempts are being made to stock coal or coke in anticipation of a stoppage of supplies from the miners. No doubt one reason for this is to be found in the fact that present requirements take all the coal it is possible to obtain. The present state of prices for coal, except house coal, is certainly not favourable to the miners' advance of 10 per cent.

Iron and Steel.—In the iron and steel trades business continues active. The armour plate mills are now assured of sufficient work for two years, independent of any orders from abroad. Messrs. Vickers have completed a huge gantry tube-dipping crane, which has a clear perpendicular lift of about 80ft. Hitherto the tubes have been dipped at Messrs. Firths', who have had long experience in this, the most crucial, operation in the construction of modern built guns. Steel castings are in increased demand. Local makers have energetically striven to produce castings true to pattern and free from gas cavities. Marine engineers show their appreciation of our steel castings by continuing to send orders. The staple trades of the town are well off for orders. The spring knife cutlers have succeeded in obtaining an advance of 10 per cent. Messrs. Hadfields' Steel Foundry Company, Limited, are experiencing a little difficulty with their workmen, owing to the introduction of some new rules; the matter will, no doubt, be arranged amicably, as this firm always treat their men well.

CARDIFF, 26th February, 1890.

Coal and Coke.—The steam coal market continues active, with prices steady, and as there is no difficulty in securing tonnage the shipment is being proceeded with satisfactorily. Colliery owners complain about the small output which they get from the collieries compared to what was produced when prices were unremunerative, but on the other hand it must be remembered that perhaps the high prices are maintained through the reduced output. Sinking operations are being carried on vigorously in the neighbourhood of Pontypridd, where there is a large coal field undeveloped within easy distance of the port of shipment. Shipowners seem to be doing an indifferent business, for while freights have been drooping the price of bunker coal and wages have been steadily advancing, in addition to which the detention at ports of loading and discharge is very great. All of this tells heavily against the steamers, and unless freights show an early improvement boats will have to lay up as in the depression a few years ago. House coal finds a ready market, and, as a large quantity is being taken for export, the prospects for the summer months are good. In the coke trade prices are not so firm, but sellers have no reason to make any concession, as they are all well sold forward.

Iron and Steel.—The market for manufactured iron and steel is most irregular, and it is exceedingly difficult to indicate prices for any particular article. In cases where works are full of orders, no abatement in the recent high figures is made, but merchants who have bought in view of an advance are able to take lower prices than makers. Steel bars are quoted at £7 15s., a price which tinplate makers are quite unable to pay with the present price of plates. The heavy fall in pig iron warrants has suspended business, buyers being convinced that the lowest point has not been touched.

Iron Ore.—There is but little doing in iron ore, all the ore obtainable in Bilbao having been bought some time ago. Rubio ore is quoted at 17s. per ton c.i.f. Cardiff and Newport, 18s. 6d. Glasgow, 18s. Middlesbrough, 17s. 9d. Tyne. Freights from the ore ports are a little firmer on account of the long detention which steamers experience at Carthagena and Bilbao, and also at the discharging ports. Steamers have to wait several days before they are loaded in Bilbao, and the same difficulty is experienced on arrival at discharging port.

BARROW-IN-FURNESS, 26th February, 1890.

Proposed Restriction of Hematite.—The makers of pig iron on the West Coast have already held a meeting with the view of determining on some system for restricting the make of hematite pig iron, in order to counteract the unsatisfactory influence of speculative sales. The policy of restriction was agreed upon, and the details of a scheme are to be submitted to another meeting shortly. Prices of warrants have this week shown very erratic movements, and were quoted on Tuesday at 64s. 6d. per ton, but makers are still firm, with their quotations up at 80s. to 82s per ton for mixed Bessemer Nos. They cannot, however, maintain this figure long unless an improved demand sets in. There has been but little new business in hematite pig iron this week.

Steel.—There is still an easy tone in the steel trade, and orders are not offering on a large scale. Makers are very busy and likely to remain so for some time, and it is anticipated in the meantime that the market will gain new life. There is, however, less inquiry for steel shipbuilding material, tinplate bars, and rails, but it is the general belief that orders are being held back with the view of placing them at an early date at lower prices. It cannot yet be determined whether prices will experience a decline, but in the meantime makers are very firm.

MIDDLESBROUGH, 26th February, 1890.

Pig Iron.—Pig iron fell in price a day or two ago, but has now recovered. It was sold in the market yesterday at 1s. advance on the day before. No. 3 G.M.B. was quoted at 53s. per ton, early delivery, by merchants, but makers refuse to break their minimum price of 60s., and prefer to go without orders in the meantime. Those who want iron prefer to take warrants, which are quoted at 52s. 4½d. to 52s. 6d. cash. Grey forge is scarce, and 56s. must be paid for it. Hematite is quoted by merchants at 78s. per ton f.o.b. nominally, but it can be had cheaper. The stock in Connal's store on Monday, the 24th inst., amounted to 179,786 tons, against 181,264 tons on the preceding Monday, showing a decline of 1,478 tons.

Shipments of Pig Iron.—The shipments last week were very poor, but over the month they are still about 4,000 ahead of the January shipments. Up to the 24th they amounted to 37,255 tons, against 33,381 tons in January to a similar date. Germany and Holland have taken more, but Scotland and other parts of England and Wales have taken less.

SUNDERLAND, 26th February, 1890.

Shipbuilding and Engineering.—The scarcity of genuine inquiries and the absence of new orders continue. These features do not, however, appear to influence the industrial classes. The claims of the engineering employés for another shilling rise, within a month of the similar rise just conceded, are being actively pushed, and at a meeting held here on Monday united action as regards the latter claim was resolved upon by eleven branches of workmen engaged in the engineering establishments. According to the first annual balance-sheet of the Wear Steel Works, the capital expended on their construction has been £133,266 7s. 9d., as against £100,000 estimated cost. Partially the increase is due to the rapid rise in the price of materials and partially to the works having been constructed so as to admit of a greater output. Nine 30-ton smelting furnaces have been provided, as against six of a smaller size, and additional re-heating furnaces have been built, so that 40,000 tons of finished steel can be manufactured per annum.

Shipping.—The unsettled condition of the Durham coal trade is affecting the chartering of vessels very considerably, but outward rates to the Mediterranean show no change. Homeward business from America continues brisk, but goods are being carried to the States at very low rates. Black Sea rates are not yet satisfactory. Local coal shipments continue low, 56,962 tons being shipped during the last week, as against 75,402 tons and 60,961 tons in the immediately preceding weeks, a decrease for the week of 18,940 tons.

River Wear Commission.—The returns for the first month of the year show a revenue of £11,055 5s. 2d., a decrease, as compared with the corresponding period of last year, of £166 9s. 3d. The falling off in coal shipments far more than accounts for the diminution of revenue, only 309,910 tons of coals being shipped, as againgst 369,000 tons in January, 1889.

The Coal Trade.—The Durham coal trade is in a very unsettled condition, and many contracts have been lost owing to the prevailing uncertainty as to the future. The miners' notices expiring in a fortnight have been handed in, but it is hoped that a general strike will be averted by the action of the colliery owners.

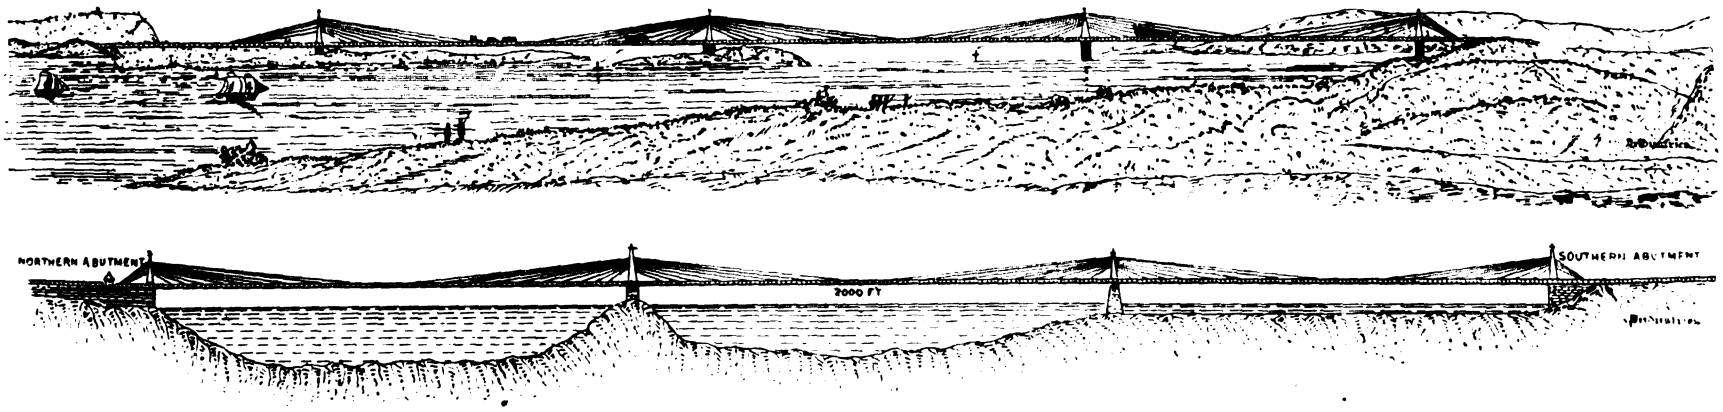
NEWCASTLE, 26th February, 1890.

Shipbuilding.—Though inquiries have largely fallen off, and the difficulty of obtaining new contracts has become accentuated of late, it is pleasant to be able to state that a few firms of this district have been able to add to their contract engagements within the past few days. Among these may be mentioned Messrs. C. S. Swan & Hunter, of Wallsend, who have recently obtained a contract from foreign owners to build three vessels of a superior class. Messrs. R. Stephenson & Co., of Hebburn, have also been among the successful competitors for such work as has recently been on offer, the firm having contracted with Messrs. Wilson & Sons, of Hull, to build a large cargo steamer for the Atlantic trade. The vessel is to be 385ft. long by 46ft. wide, and will carry upwards of 5,000 tons of cargo. The engines, which will also be supplied by Messrs Stephenson, are to be constructed with a special view to the development of a high running power in rough weather. They will be capable of driving the vessel at a speed of 13 knots an hour, but their full power will only be exercised in special circumstances. This is the third steamer ordered from Messrs. Stephenson by this well-known firm of steamship owners, and it is the only one which has been given out by them to contract since the opening of the year. It may be added that the vessel will be fitted throughout with the electric light, will have eight powerful steam winches, and will be supplied with every appliance which can tend to make her unique as a cargo boat.

Engineers' Wages and Hours.—On Tuesday afternoon an important conference of master engineers and representative workmen connected with the engineering works on the Tyne and Wear took place at Newcastle, to discuss the men's claim for a further advance of 1s. per week in the wages rate (1s. having been already conceded at the beginning of the month), and the alteration of the stopping time on Saturdays from 1 to 12 o'clock. After a prolonged discussion, the employers offered an additional 6d. per week, but declined to make any alteration in the working hours. This decision, which is understood to be final, will be immediately placed before meetings of the men at the various centres, and the result will be made known to the employers' secretaries as soon as possible. If the men persist in their demand for an hour less working time on Saturdays, a strike must ensue, as it is definitely understood that the employers will not negotiate upon the matter, and the subject is one which scarcely admits of a settlement by arbitration.

The Coal Trade.—The shipments of coal and coke at Tyne Dock for the week ending February 22nd amounted to 107,686 tons, being an increase of 1,898 tons as compared with the shipments for the corresponding week of last year.

Chemicals.—The Tyne Improvement Commissioners have just issued their statement of goods imported and exported into and from the Tyne during 1889. These figures go to show the continued decay of the Tyne chemical trade. The exports of soda crystals, when compared with 1888, have fallen off 18 per cent. Alkali and soda ash exports have decreased 35 per cent., bleaching powder 9 per cent., and bicarbonate of soda 34 per cent. On the other hand, caustic soda exports have increased 31 per cent., and there was a slight increase in the exports of manganate of soda.



DUNDEE, 26th February, 1890.

Flax and Jute Trades.—The market here has been dull of tone during the past fortnight. In flax there is little doing. Very little is at present doing in goods ex-warehouse, and sales on contract are limited with a downward tendency in quotations. The flax yarn market is in favour of buyers, but transactions are on a small scale. There is no change in the home and foreign demand for linen goods. Manufacturers are still well employed on past orders, and they are looking forward to a better inquiry in the course of the spring. Sailcloth is in fair request at firmer rates. In the Calcutta market loose jute and baled jute are meeting with a slow sale. Supplies are believed to be good, and buyers are holding off in expectation of a decline in quotations. The demand for Dundee goods in New York is limited, and the tendency of the market weak. Burlaps, 40 in 10½oz., are this week quoted at 5½c. to 5⅝c. per yard, against 5⅝c. last week. In this market jute sales are of limited extent, and it is anticipated that prices have not touched their lowest point. First marks have been selling at from £13 10s. to £13 5s. c.i.f. Jute yarns are slow of sale, and buyers are not disposed to transact business unless at a reduction The market for goods is not animated, but prices are fairly well maintained. There is less doing in tarpaulin.

Advertisements intended for insertion in the current week's issue should reach our London Offices not later than first mail delivery on Thursday morning. Scale of charges for displayed advertisements on cover and inside pages will be forwarded on application. Orders for single advertisements must be accompanied by payment in order to insure insertion, the charge for which is 2s. 6d. for the first four lines or under, and 8d. for each additional line. Situation advertisements (Vacant or Wanted) 1s. for two lines or under, and 6d. for each additional line—which averages eight words. While all practical regularity in the insertion of serial advertisements will be observed, it can only be absolutely guaranteed in the case of those ordered to appear weekly.

As we go to press early with certain of our advertisement pages, all Alterations to Standing Advertisements should reach the Publisher not later than 2 o'clock on Wednesday afternoon in each week.

All accounts are payable to GEO. CAWLEY, 358, *Strand, London, W.C. Cheques should be crossed Manchester and Liverpool District Banking Co., Limited, 75, Cornhill, London, E.C. Post Office Orders should be made payable at the Post Office, 369, Strand, London, W.C.*

FRIDAY, 28TH FEBRUARY, 1890.

THE OPENING OF THE FORTH BRIDGE.

IN February, 1883, the actual work of the building of the Forth Bridge had just begun; now, after seven years, the bridge is completed, and will be formally opened by His Royal Highness the Prince of Wales on Tuesday next. Therefore within a few days this great bridge will be as much a matter of course as any other part of our railway system. The technical features of it have been so amply described in our "FORTH BRIDGE SPECIAL," just published, that it is unnecessary to do more than refer to them most briefly in this place. The wisdom of adopting the cantilever and central girder principle has been entirely justified by the event. The testing of the bridge, which seems to have been carried to all reasonable extent, has shown that the calculations of the deflections due to the passing of trains have been amply vindicated, while the repeated severe gales which have subjected the bridge to tests of wind pressure have found even the temporary erections on it fully able to withstand the most severe storms which have swept the Firth of Forth during the past seven years. The one quality which such a structure ought to possess, in the eye of the public who are to use it, is stability, and there is every reason to believe that this quality has been very thoroughly secured. Confiding as the public usually is in the skill of professional people, there has been—owing to the Tay Bridge disaster, and owing also to recent collapses of bridges in America—an anxiety on the part of the public lest there should be any unseen element of weakness in this structure, over which there must be so enormous a daily traffic. The Forth Bridge Railway Company, the engineers, and the contractors have clearly all along set themselves to ensure that a feeling of confidence in the strength of the bridge should spontaneously arise in the mind of everyone who sees it. Both design and workmanship have from the beginning been directed to the end of producing a manifestly strong construction. It is no rhetorical exaggeration to say that, had the bridge been built by national resources, regardless of cost, it could not have been raised with a more single eye to its thorough efficiency. So many considerable things have to be done nowadays under the stress of competition, that it is a hopeful sign for a company to have set itself, not to meet minimum requirements, but to meet a reasonable maximum. The result is that everyone who sees the bridge—and who will not, ere long, if possible?—must be impressed with its enormous reserve of strength. For the public this is the first, second, and third essential. But it strikes some of the non-technical public in another way. Mr. William Morris, in an offhand speech at the Art Congress in Edinburgh in November last, pronounced the bridge the climax of ugliness in iron. It is perhaps beside the question to discuss the Forth Bridge as if it were a work of art; but it is worth while to vindicate it from the accusation of being a paragon of ugliness. Mr. Baker has, in answer to Mr. Morris, made a felicitous quotation from Mr. Ruskin, to the effect that strength and beauty are closely associated. "If a workman is working in iron, he should insist upon and exhibit its strength and tenacity, and he will invariably find the material grateful, and that his work is all the nobler for being eulogistic of the substance of which it is made." This really answers Mr. Morris's objection. What was required was not a piece of decoration over a mile long and a hundred and twenty yards high, to be set into a landscape with a river, but what was required was a manifestly strong bridge; and a manifestly strong bridge has been built. If we were able to dismiss from our minds all our unreasoned prejudices concerning this or that form, or curve, or line, and then asked ourselves what form we liked fundamentally, would it not be a form which in the first place was structurally sound, and is there not therefore a utilitarian basis for our æsthetics? One of the virtues of the design of the Forth Bridge is that there is no attempt at ornamentation of any kind whatever. The columns, top and bottom members, struts and ties are left to tell their own tale; they are there for use and not decoration. Yet there is, from such a distance as may enable one to take the whole design into the range of vision, a certain gracefulness of outline, a certain obvious naturalness of pose as it were, an equipoise of parts—in brief, just those elements which go to explain why it is we like a work of art and don't like a daub. The Forth Bridge owes little of its impressiveness to its mere magnitude. A model of it is impressive. In this it is quite different from the Pyramids, which appeal to nothing except our sense of size. They are big; but if they ever are beautiful, their beauty is due, not to any artistic qualities that they have—for they have none—but to atmospheric causes. In the same way a railway embankment or a heap of waste shale might be considered beautiful. But the Forth Bridge has elements of beauty in its design, and these elements of beauty, consisting as they do in detail, in lines, and forms, carried out in material on a scale of immense size, must be observed from an appropriate distance. It is true that the bridge dwarfs the landscape on either side, but this is the fault of the landscape: the height and form of the bridge were conditioned by the breadth and depth of the river, not by the height of the hills on one side or the other. Looked at, then, from the point of view of rational æsthetics, we expect Mr. Morris's dictum would be found erroneous, and that the bridge, from its definite adaptation of obvious means to obvious ends, had, at all events, fulfilled one of the canons of art. It is trickery, and not art, which conceals how a thing is done. So much for the æsthetic aspect of the bridge; the engineering merits of it are already pretty amply expounded and recognised.

There is, however, one aspect of it which deserves special notice, and that is its place in the Scottish railway system and its probable effect on the future of railways in Scotland. Its connection with the railway system is shown in a map published on another page, and it will be seen that the chief advantage of the opening of the bridge will be the saving in time and distance on the journey between Edinburgh and Perth and Dundee, and, therefore, a corresponding saving in the journey between London and the North of Scotland *viâ* Edinburgh. Since the Forth Bridge is an integral part of the North British Railway Company's system, that company will benefit from it chiefly; but the East Coast Route as a whole must benefit largely. The existing traffic which hitherto has gone by Granton, and by payment for way-leaves over the Caledonian line *viâ* the Forth Bridge at Alloa, will necessarily cross the new bridge, thus saving the ferry on the one side, and the way-leaves to the Caledonian on the other. In addition, the attractions of the Forth

Digitized by Google

Bridge and Edinburgh combined will doubtless draw off some portion of the passenger traffic from Euston north by the Caledonian system *vid* Stirling. Indeed, the competition between the Caledonian and the North British Railway Companies for predominance in Scotland has, by the building of the Forth and Tay Bridges, and by other means, reached an acute stage. The proposed amalgamation of the North British Railway and the Glasgow and South Western Railway has resulted in a counter-proposal by the Caledonian. Thus, Scotch railway matters will shortly prominently occupy the attention of Parliament. One of the most striking features of the financial situation in Scotland during the past few years has been the remarkable and steady rise in the price of Scottish railway stock. The strong position which the Scottish railways hold financially has led them into the various enterprises which they have now on hand, and the great increase in strength of the North British Railway Company relatively to the Caledonian, especially in the few past years, has brought the two companies into very close rivalry indeed. For many years railway rivalry in Scotland has taken the form of extensions of lines and building of stations to meet a continually growing traffic, rather than of competition in passenger fares, or even in goods or mineral rates, except in special cases. Now it would appear within the bounds of possibility, as if the two great railways, facing each other in a duel for supremacy, should elect to fight it by reducing rates. There is, however, an alternative which railway administrators in Scotland are beginning seriously to look forward to—that is, the absorption of all of the smaller railways by the two great ones, and the final amalgamation of these into one great railway monopoly. There can be no doubt whatever that, if this were permitted, it would be necessary to devise very special means for preventing the public interests from being jeopardised by such a combination. The railways are on a unique footing as regards the State; they have been privileged and State-regulated from the beginning, and they owe their position of power as the monopolisers of inland carriage to the privileges thus granted. It may be necessary in this case to extend State-regulation in order to prevent a State privileged corporation from wielding its power to the public disadvantage. The opening of the Forth and Tay Bridges, and the other extensions of the railway system which are now being constructed, or for which powers are to be asked in Parliament in the session just entered upon, must bring the Scottish railways within measurable distance of some such issue as that indicated. The Forth Bridge Railway Company and the various railways among whom its stock is held are to be congratulated upon the successful completion of an enterprise which has only been carried out by the indomitable perseverance and courage, and by the hearty co-operation, of the able men who have financed it, designed it, and built it.

THE EXEMPTION OF MACHINERY FROM RATING.

In our issue of the 15th November last we directed attention to the circumstances which had led to the institution of the National Society for the Exemption of Machinery from Rating, and at the same time pointed out some of the principles which should guide legislation in the matter. We mentioned that not only was the special case which had raised the question being carried to the highest legal tribunals, but also that a Bill to secure the exemption of machinery from rating was being promoted by the Associated Chambers of Commerce, and that the Parliamentary and pecuniary support which had been given or promised was most encouraging. The energetic manner in which the Chambers of Commerce branch associations took up the subject in all the manufacturing centres was a guarantee of a successful issue. We have been informed that, by the aid of Mr. Winterbotham, M.P., a Bill for carrying out the objects of the Society has been ordered for second reading in the House of Commons on the 16th of April. Such a matter as this should of course be decided entirely on its merits, and we are sure that the promoters of the Bill have no other object in view; but the amount of ignorance or apathy on all matters lying outside of ordinary everyday experience is so great that it becomes all who are interested in the subject to enlighten our legislators as to the objects in view, and to the dangers which would arise if the decision from which appeal is being made be not overturned. The committee of the National Society for the Exemption of Machinery from Rating has therefore issued a circular requesting that those who are directly interested in the subject should try to place it in all its bearings before such Members of Parliament as they happen to know, as they think that so favourable an opportunity for bringing their work to a successful issue may not soon occur again. As we entered into the merits of the question in the article to which we have referred, we need not here repeat any of the arguments we used in support of the position taken up in the Bill, but we hope that these will be carefully studied by all concerned, so that a just decision may be arrived at. Any information which may be desired on the subject may be obtained from the secretary, Mr. Humphreys Davies, 22, Buckingham Street, Adelphi, London, W.C.

THE EDINBURGH UNDERGROUND RAILWAY.

For some time past the people of Edinburgh, especially those resident in the neighbourhood of Prince's Street, have been agitated about the proposals of the Caledonian Railway Company to have an underground railway, or, more correctly, a series of such railways, in their neighbourhood, and discussions on the subject have been both loud and long. At a recent meeting of the Town Council it was unanimously agreed to petition against the Bill which is being promoted by the Caledonian Company for carrying out their object, and in the face of this opposition there is not much probability to its being agreed to by Parliament.

The subject can be looked at from several points of view, and the decision which is arrived at will, of course, depend on the relative importance of the various factors in it. The Town Council instructed Sir John Fowler and Mr. Benjamin Baker to report on the matter, and they, of course, confined themselves mainly to the engineering problems involved. The whole of the work would present no serious difficulties in its execution, although it might cause a considerable amount of temporary inconvenience. It is estimated that the operations of construction for the Prince's Street part would occupy about two years, and the consulting engineers are of opinion that, with energy and good arrangements, it is quite possible that they might be completed in that time. In order, however, to do this without seriously interfering with the street traffic, it would be necessary to work at night, and thus render the two years a period of great discomfort to visitors or persons having their residence in Prince's Street, and to hotel-keepers and others who are dependent on visitors to Edinburgh this discomfort might be a very serious loss. The engineers add, however, that if the permanent advantage to be attained by the citizens of Edinburgh generally were very great it might be necessary for private persons and particular localities to submit to such temporary loss and discomfort. The consulting engineers have reported that they did not think that structural injury need be apprehended to house property by the construction of the railway if proper precautions be exercised. They admitted, however, that a considerable amount of vibration was inevitable with passenger, and still more with goods, trains, and they pointed out that an amount of vibration which would be immaterial in many cases would be highly prejudicial in the instance of Prince's Street, where for many months in the year there is probably a greater number of persons whose sleep would be dependent on quiet during the night hours than would be found in the same length of street in any town in Great Britain.

The consulting engineers then consider the inconvenience to passengers by the proposed railway from defective ventilation, and point out that if the present plan be carried out the difficulties of ventilation would be considerably greater than in any closed part of the Inner Circle Railway in London. While admitting that if sufficient power be provided to work fans it is possible to obtain any degree of ventilation required, still it is proper for safe guidance to look at what practically happened in the underground railways of London, where fans were proposed, but were found so costly that other cheaper, although less effective, means were adopted. At the present time there is only one place where a fan is at work on the whole of the Inner Circle Railway, and that is where the stations are very near together. With present experience in other railways the consulting engineers say that it may be concluded that to efficiently ventilate the railway down Prince's Street there would be required engines and fans of great power, placed in or near the street, and causing noise and disturbance, or the still more objectionable alternative of openings in the street, and they are of opinion that only a great public necessity would justify either of these alternatives, having reference to the high and valuable character of the business and residential property in Prince's Street.

Apart altogether from the engineering aspects of the question, it was pointed out that if the works were carried out as proposed they would inflict an injury of the grossest kind on the architectural and artistic features of the city for which Edinburgh is at present famous. Professor Baldwin Brown said that any such wanton destruction as might possibly be entailed should the scheme pass would involve a blot upon the reputation of the city for good taste, and would be remembered against the citizens by future generations. Taking everything into consideration the Town Council arrived at the unanimous decision to oppose the scheme, and, on the whole, we do not see how they, as guardians of the public interest, could have done otherwise. Some of the objections urged to the scheme might in time be reduced by improved mechanical or electrical arrangements; but it would be a grave mistake to sacrifice either the comfort or the appearance of the finest city in the kingdom for a small matter of convenience. There is certainly need for improved station accommodation in Edinburgh, and the consulting engineers give some hints which might be adopted with advantage. If the North British and the Caledonian Railway Companies, instead of attending only to their own interests, would unite and bring forward a scheme which, while respecting the rights of owners and of the community, also met the convenience of the general public, it would receive the support of all concerned, and would in the end lead to their own advantage.

THE RAILWAY AND CANAL TRAFFIC ACT, 1888.

At recent sittings of the inquiry now being held before Lord Balfour of Burleigh and Mr. Courtenay Boyle, representing the Board of Trade, the case for the traders of the country has been under consideration. In their behalf it is alleged that the railway companies' classification is altogether incomplete, and that the attempt to increase the charging powers of the companies is contrary to the intentions of Parliament, and will adversely affect the industrial position of Great Britain. With regard to the former the traders urge the acceptance of the Clearing House classification; and as to the latter, they uphold the adoption of one working schedule of rates, as opposed to the constitution of a statutory and a working schedule. It seems probable that in this respect they are doomed to be disappointed, and, speaking generally, we are not sure whether the attainment of their object would prove an unmixed benefit. In times of good trade, the expenses of railway traffic are much enhanced, not only from the increase of goods to be handled, but from higher prices of fuel and labour. If the statutory rates are to be the working rates, it is evident that an average schedule would have to be fixed which would prove a serious burden in times of great depression in trade. Provided the maximum rates are not fixed above a figure suited to times of good trade, it seems somewhat in the interests of commercial centres that in periods of severe depression the companies should have the power to reduce their charges. During the years 1886–88 many instances of reduced charges came under our notice, and it is well known that for various reasons the companies do not, as a rule, exercise their maximum powers. As long as the railway transit monopoly exists, traders cannot expect, either through Parliamentary interference or otherwise, that their lot will be a happy one.

Comparisons have been made between the rates in this country and those prevalent on the Continent, and it is a recognised fact that such comparisons are uniformly in favour of Continental rates.

THE LATE SIR ROBERT KANE, F.R.S.

To the younger generation of readers the name of Sir Robert Kane may be so little known that they will be surprised to hear of his death, which occurred in Dublin, on the 16th inst., in his 80th year. The work which perhaps brought him most prominently before the public was his book on "The Industrial Resources of Ireland," which was published forty-six years ago, and which in many respects is still a standard work and a model of exactness and method, and now, when there is talk of

Digitized by Google

attempting to develop the resources of Ireland, it is always referred to for information.

Sir Robert Kane, F.R.S., was born in 1809 in Dublin, and was the son of a manufacturing chemist of that city. His early life was devoted to the study and practice of the medical profession, but his leanings were towards the educational and literary sides of his work, and in 1834 he was appointed Professor of Chemistry to the Apothecaries' Hall of Ireland. In 1844 he was appointed Professor of Natural Philosophy to the Royal Dublin Society, a position which he held until 1847, and he obtained various honours for his researches in chemistry during this period. He took an active part in the work of the Council of the Royal Irish Academy, and afterwards became its secretary, a position he held until his appointment as first President of Queen's College, Cork. In 1843 he delivered a course of lectures on the industrial resources of his country, the substance of which appeared in the book to which we have alluded. In 1846 a Museum of Irish Industry was organised at his suggestion, and he was nominated its Director, a position which he occupied for a considerable time along with the Presidency of Queen's College, Cork. The two positions, however, being found incompatible, he resigned the latter in 1864. In 1875 he was appointed one of the Commissioners of National Education, and his death creates a vacancy on the Board. Of late years he lived in comparative seclusion, taking little part either in scientific or public matters. It is said that the distinction which gave him the greatest pleasure of any he ever received was that he was the father of Captain Kane, of the "Calliope," the hero of the Samoan hurricane last year.

Letters to the Editor.

FOG AND ATMOSPHERIC ELECTRICITY.

To the Editor of "Industries."

Sir,—As of late years great advances have been made in electrical science, I should be glad to know, from some reader, through your columns, whether means have been found to ascertain the electrical condition of the atmosphere at any time, and whether it is, or not, affected by fog.

It has long been a moot question in maritime circles whether fog does, or does not, affect the mariner's compass. A very competent observer, the late Captain Saxby, asserted that it did, and mentioned, in proof, that on one occasion a convoy of thirty sail all found themselves steering a wrong course through fog. Others, on the contrary, assert that it is not in consequence of error of the compass, but owing to the tide or to a current if a vessel gets out of her course in a fog.

My own opinion is that fog does affect the mariner's compass, and, though I am not an electrician, the following reasons appear to me conclusive: magnetism is a form of electricity, and so is lightning; lightning is in the clouds, and a fog is a cloud. Moreover, in the normal course of things, a cloud should rise in the air, whereas a fog descends.

Yours, &c.,
Wm. H. Daniels.

7, Cavendish Grove, The Avenue,
Southampton, February 24th, 1890.

THE KENT COAL DISCOVERY.

To the Editor of "Industries."

Sir,—While the announcement of the discovery of coal in Kent was probably wholly unexpected by the general public, it no doubt also came as a great surprise to many of those whom it will most materially affect, and who have been better informed upon the opinions of geologists as to the occurrence of coal in the south-east of England. Upon the first reception of the news, considerable doubt was expressed as to its truth, as it was felt that the engineers could easily have been misled by some lignite from the Kimmeridge clay, some jet from the lias, or a local development of trias plant beds. At the annual meeting of the Geological Society it was announced by the President that Professor Boyd Dawkins had identified some of the plants found with the coal as carboniferous species, and thus all doubt in the minds of geologists is set at rest. But, as many who are not geologists may not appreciate the value of this evidence at its true worth, I should like to refer to the reasons which have led geologists to believe in the existence of coal in the area in question.

It is now more than sixty years since Conybeare and Phillips first called attention to the striking resemblance of the coalfields of Belgium and Bristol, and concluded that they were probably connected beneath the newer rocks that occupied the area between them. The Bristol coalfield was found in its eastern margin to dip below the new red sandstone, and this in turn was covered by the various members of the jurassic system, and these by the cretaceous. It was concluded that the whole of these would intervene between the coal measures and the base of the tertiary rocks in the London district—that is to say, that the coal would be buried by at least 8,000ft. of superincumbent deposits, or could only occur at twice the maximum depth at which it is thought coal will ever be worked. Moreover, it was pointed out that, as the coal seams of the north and west of England are traced to the south-east they deteriorate in value, and thus, even if the coal could be reached, it would be almost valueless. Hence the question was thought to be of no practical value, and the discussion was regarded as possessing only an academic interest. Serious attention was first called to the matter in 1855, when a masterly memoir was presented to the Geological Society by Mr. Godwin Austen. In this he showed that the coal fields of Belgium, Northern France, and Bristol had once been continuous, that there was no reason to expect any serious deterioration in the value of the coal over any large part of its area, and that, as the lower mesozoic rocks in the south-east of England had probably thinned out in that district, the underlying carboniferous rocks would occur at a depth of little over 1,000ft. Very shortly afterwards the truth of this remarkable prediction was proved by the boring of a well at Meux's brewery in the Tottenham Court Road, when the old palæozoic rocks were struck at a depth of 1,066ft. Henceforward no subject has been watched with greater interest by London geologists than the exploration of this ridge of rocks which connects the coal fields of Belgium and the West of England. Borings alone, however, could throw any fresh light upon the subject, and these have been few in number, and as far as the present problem is concerned, not well placed; only one, the unfortunate attempt made by the British Association at Battle, in Sussex, was especially undertaken to settle this problem. Nevertheless, the palæozoic rocks have been struck at depths varying from 800ft. to 1,200ft. in borings at Kentish Town, Ware, Cheshunt, Crossness, Chatham, Harwich, Streatham, and Richmond. Until last week the coal measures had never been found, but the borings had ended in red rocks of doubtful (probably Devonian) age, Devonian or Silurian rocks. The borings had, however, afforded an almost complete verification of Godwin Austen's prediction, and as the older palæozoic rocks seemed to dip to the south geologists felt no doubt that somewhere in that direction the newer palæozoic rocks containing the coal measures would be found. Small fragments of coal had actually been obtained from the Richmond boring, showing that coal did once occur *in situ* in that district. It has, however, been impossible to predict exactly where the coal measures would be found, as they occur both in Belgium and the west of England as isolated narrow basins; thus, that of Liége is forty-five miles long by three-eighths of a mile broad, and similar proportions may be seen in the coal fields of the Ruhr, of Aachen and Hainaut. The same arrangement probably obtains in the south-east of England, and the coal basins may be found as long narrow basins surrounded by older rocks. Hence geologists have had to wait for more borings to give a better idea of the general distribution of the older rocks before predicting exactly where a search for the coal is most likely to be attended with success. Important evidence was expected from the Dover sinking, though no one dared to hope that, by a lucky chance, the coal should itself be struck. Until the dip of the beds at Dover can be ascertained, which probably cannot in this case be done, it is perhaps rash to prophesy the distribution of the coal measures, but they probably occur in a series of isolated basins tending north-westwards from Dover along a curved line following the North Downs. Thus they may be expected between Ashford and Canterbury, and between Maidstone and Chatham, and further west in the neighbourhood of Reigate and Guildford, and so on to the outcrop in Somersetshire. In view of the paramount importance of the discovery, which may have results absolutely revolutionary to British industry, the necessity for experimental borings along the line indicated may well be pressed upon the Government and local authorities. Cheap fuel may cause the return to London of the industries once the source of its prosperity, but which have migrated to the north, and the pressing social problems of East London may find their solution in the time when is fulfilled the old geological prophecy, "that the day will come when coal will be worked in the south-east of England."

Yours, &c.,
F.G.S.

London, February 24th, 1890.

THE INSTITUTE OF MARINE ENGINEERS.

A meeting of the Institute of Marine Engineers was held on the 10th inst., under the presidency of the Honorary Secretary, when the discussion on Mr. Sommerville's paper on "Ventilation and Heat Radiation," read at the previous meeting, was continued.

The chairman opened the proceedings by giving a brief *résumé* of the various ideas suggested by the paper, of which proof copies had been already supplied to members for the purpose of discussion. The presence of carbonic acid and other gases, and modes of expelling them, he referred to, and the plan adopted in mines for ventilating workings and drawing the foul air to the upcast was given as the foundation of a good system of ventilation. When, however, in place of the upcast being through the stokehold as its natural and proper channel, the engine-room skylight was made to usurp the province of the funnel, the results were highly detrimental both to ventilation and the efficiency of the machinery, inasmuch as the draught was away from instead of towards the furnaces, and the coal-dust and floating particles from the stokehold were carried into the engine-room, resulting in the open oil-boxes becoming filled with grit, which tended to heat the exposed bearings and bring about worry, anxiety, and fatigue to the engineers, and prospective expense to the ship. The want of attention given to the accommodation required for engineers when off duty in many of the smaller lines of steamers was alluded to, and the frequent changing of engineers resulting from this was remarked upon as being detrimental both to the interests of the owner and the machinery. Attention was next called to the injury done to boilers by injudiciously allowing the cold air to pass down the stokehold ventilators in great quantity, especially when cleaning fires, as it frequently was the cause of leaks at the back ends of the fire-boxes. In connection with this it was suggested that it is a good plan to have an arrangement of gear led into the stokehold for shifting the ventilator cowls with their head to wind, when the furnace or tube doors require to be opened, so as to lessen the introduction of cold air, and thus make the ventilator nearest the doors in question an upcast. The disadvantage of fans driven by the main engine shaft was alluded to as being only available when the engine was in motion, whereas ventilation is wanted quite as much when the steamer is at ports of call and the main engines stopped. The various forms of ventilator cowls were referred to; also various systems which had been tried with more or less success, such as the system of leading a pipe into an annular space around the funnel or into the funnel itself, with or without the application of exhausting fans.

The discussion was entered into by Messrs. J. McFarlane Gray, D. G. Hoey, J. H. Thomson, W. W. Wilson, R. Duncan, W. M. Thomas, and Captain Froude, while Mr. R. Adam read the remarks of Mr. Buckwell, who was unable to be present. During the discussion the theory of ventilation, and the principles on which the theory is based, were shown and illustrated by diagrams. The necessity of having a proper system of uptake and downcast was enforced, and the need for an efficient arrangement of ventilation, based on true scientific principles, was shown. The system in operation in some of the Channel Service steamers was described in the remarks by Mr. Buckwell as being very effective. In this system the vitiated air is drawn into an annular space around the main funnel. This space is divided vertically, the one portion being used for ventilating the forward part, and the other the after part of the ship. Another system was referred to, in which the foul air is drawn by artificial appliances from the various parts of the ship and discharged into the funnel, thus providing ventilation and forced or induced draught at the same time. The extraordinary disregard which is paid by many to the loss of coal involved in uncovered steam pipes, boilers, and other portions of the machinery, was commented upon; also the want of thought displayed in arranging the ventilators in steamers without regard to scientific principles. It was suggested that the various ideas brought forward in the paper read, and the discussion to which it had given rise, should be embodied in a future paper and brought to some practical issue.

THE MANCHESTER ASSOCIATION OF ENGINEERS.

At the meeting of this Association, held on the 22nd inst., Mr. G. Kiernan read a paper on "Continuous Brakes."

In commencing his paper, the author gave the history of the subject so far as it concerned this country, and recited the well-known stipulations of the Board of Trade in regard to brakes. The five requirements insisted on by that Department had been embodied in an Act passed last year, and the Board of Trade had, by the powers then given them, fixed the time for the adoption of continuous brakes complying with their conditions, this term expiring on the 24th April, 1891. Mr. Kiernan then proceeded to give a number of figures showing the relative employment of the automatic vacuum and the Westinghouse brakes. The former, he stated, was used in this country by companies having 12,000 miles of railway, and the latter on a length of 6,220 miles. In 1878 mechanical brakes were in use on 4,350 vehicles; in 1883 on 9,000; and in 1889 on 3,000 only. In the same time the use of atmospheric brakes had increased from 3,380 vehicles to 56,000. Dealing in a similar way with vacuum and pressure brakes, he found that the numbers in use of the former in 1878, 1881, and 1889 respectively, were 2,415, 8,700, and 37,800; and of the latter in the same years, 1,059, 6,000, and 18,000. Distinguishing between automatic and non-automatic or simple vacuum brakes, the numbers were as follows:—In 1878, 1,000 automatic and 2,500 simple brakes were in use, while in 1889 the numbers were 46,200 and 9,600. Further figures were given to show the striking advance made in the use of the vacuum automatic, and the cause of this was found in the simplicity and efficiency of the mechanism which allowed, he said, of the nicest regulation with less liability to error than any other brake. The chief difference in the vacuum and Westinghouse brakes lay in the fact that in the former the piston itself is made large enough to apply the necessary pressure to the wheels, while in the latter it is merely used to control a valve which admits air to and from the brake cylinder.

The author then proceeded to deal with the most recent development of air-brakes—viz., their application to long trains of, say, fifty coaches, the total length of which would be over one-third of a mile. Unless the brakes were made very quick in action the front part of

Digitized by Google

the train would be stopping before the rear had the brake on, and the train would be subject to severe shocks. It was impossible entirely to avoid this defect, but it could be so minimised that all practical objection would be removed. Both classes of brake had been remodelled to meet the requirements of this class of traffic, and, in a trial made with an improved Westinghouse brake at the Brussels Exhibition, pressure was applied on the twenty-fifth coach wheels in two and a half seconds. A special model of fifty cylinders and 1,830ft. of 2in. piping had been constructed by Messrs. Gresham & Craven, Limited, Salford, to correspond with actual working conditions, the cylinders being in series separated by exactly the length of pipe existing in actual practice. A trial made by Sir Douglas Galton gave the result that the brake was applied on the tenth cylinder in $\frac{1}{10}$ second, on the twentieth in $1\frac{1}{2}$ seconds, on the thirtieth in $2\frac{1}{4}$ seconds, on the fortieth in 3 seconds, and on the fiftieth in $3\frac{1}{2}$ seconds. Thus the Westinghouse applied the brake on the twenty-fifth coach in $2\frac{1}{2}$ seconds, and the vacuum on the thirtieth in $2\frac{1}{4}$ seconds. In order to facilitate rapid action a special valve had been made in each case. In the vacuum this valve was fixed on the train pipe, and consisted of a hollow stem valve with a ball valve in the centre, a diaphragm placed so as to lift the valve as afterwards described, and a pin projecting into the hollow stem. So long as the brake was off, air could enter the cylinder freely from the train pipe, the pressure upon the valve being greater than that on the diaphragm. When a rapid application was required the vacuum in the train pipe was destroyed up to the first valve. This caused the ball valve to lift, and reduced the vacuum below the stem valve, the pressure on which became less than that on the diaphragm. This lifted the stem valve and allowed air to enter the train pipe freely, the ball valve, which rose with the stem valve, being pushed off its seating, and the air flowed to the underside of the piston and applied the brake. A graduated application was obtained by a slow admission of air, and the ball valve was not in this case raised from its seating. In the Westinghouse the triple valve was operated upon, and in the author's opinion this valve is complicated. It was designed to admit a little air into the cylinder, and thus more speedily reduce the train pipe pressure. As now constructed the so-called triple valve consisted of five different valves, and an application necessitated the use of all of them. As the pressure was released the air to the right of a piston valve was allowed to escape, and the air pressure in the reservoir forced the piston over, thus closing a feeding groove, moving a slide valve, and closing the atmospheric port, which at the same time was opened to the reservoir. In this way the compressed air entered the cylinder and applied the brake. A detailed description of the method of making gradual and quick applications of this brake was then given, after which the question of the amount of air used was dealt with. In the first case it was assumed that the brake was fitted to a train of ten coaches with 400ft. of piping. The automatic vacuum, under these circumstances, required 61,812 cubic inches of air when fully applied, and the Westinghouse 287,338, the latter being an increase on that used with the ordinary type of over 100,000 cubic inches. With trains of 50 coaches and 2,000ft. of piping the air required by the two brakes were respectively 256,156 and 688,650 cubic inches, the vacuum brake, he said, again having the advantage. Quick action brakes had not yet been fitted in this country, although several long train trials had been made on the Manchester, Sheffield, and Lincolnshire Railway. After remarking that the Indian Government had adopted the vacuum brake, the author concluded by saying that he thought the time had come when a universal brake should be adopted.

In the course of the discussion which followed, some objection was taken to the size of the pipes used for the vacuum brake because of the extra weight and difficulty of fitting, and it was pointed out that in some places the mechanical brake was preferred for use on steep inclines.

Mr. C. F. Budenberg said he had tested the action of the rapid valve on the model at Messrs. Gresham & Craven's works, and could confirm the results obtained. He thought, however, that it would be difficult to put on the brake slowly, as he had found it extremely difficult to prevent it going on full. The valve named was very simple, and one feature of the arrangement was that the release of the vacuum brake was gradual and without shock. The point to be aimed at was to prevent skidding, and this was a cardinal feature in the use of the regulating valves. A previous speaker had referred to the cost of air, but if the curves of exhaustion and compression were plotted it would be found that the proportional values of the work done were as 1 to 5. Even assuming that ejectors were not so effective as pumps, it would be seen that there still was a large margin left in favour of the former.

In replying to the discussion, Mr. Kiernan said that the behaviour of air brakes on inclines was quite satisfactory and equal to that of mechanical brakes. To produce a vacuum in the whole of a train of the length named would require with a small ejector 3 to 4 minutes and with a large one about 50 seconds. With the Westinghouse plant the filling of the reservoir with air at the required pressure would take 15 to 20 minutes, so that after all the amount of air used did count in the calculation. With reference to the difficulty of application referred to by Mr. Budenberg, this could be easily overcome by a slight modification in the application valve. While the mechanical construction of the Westinghouse brake was probably more ingenious than any of its competitors, still, for simplicity and efficiency he thought the automatic vacuum was far superior.

FARBELECTROCHEMISCHE MITTHEILUNGEN. By Dr. F. Goppelsroeder. WENZ & PETERS, Mülhausen-i.-E. 1889.

Dr. Goppelsroeder exhibited at the Manchester Exhibition a collection of the more important of the results which he has obtained in his endeavour to dye by means of electrolysis. Before 1887 he had contributed papers to the Austrian *Wollen und Leinen Industrie Zeitschrift*, in which he gave details of his earlier experiments in this direction. The present pamphlet consists of a *résumé* of his work, and describes the Manchester exhibit in detail. Briefly, Dr. Goppelsroeder's experiments may be described as the utilisation of the oxidising and reducing action of the electrodes of a battery for the purpose of producing changes in the colour of dyestuffs on the fabric. There may be in the future an industrial opening for his experiments in printing with these readily reducible or oxidisable colours; at present, however, they form only an interesting series of lecture experiments illustrating the chemical constitution and reactions of some of the aniline dyestuffs. The electric pen might, however, be considered as an industrial application. The pen forms the positive electrode, and passes over a sheet of paper soaked in aniline hydrochlorate solution resting on a pad containing the negative electrode. The chlorine and oxygen liberated at the point of contact of the pen cause the dehydrogenation of the aniline molecules to aniline black, and leave therefore a black line where it has passed over the paper. The pamphlet concludes with an historical sketch of electro-chemical telegraphy.

THE AMATEUR'S WORKSHOP. By the Author of "Pattern Making," &c. London: SWAN SONNENSCHEIN & Co.

In the present day it is highly desirable that almost every one should have a considerable knowledge of practical mechanics, and be able to use his hands and some of the more common workshop tools, in such a manner as will fit him to keep things in order in any establishment not of a purely mechanical nature with which he may be connected, without the necessity of sending for a tradesman for every little job. Hence the demand which has arisen for manual training in connection with schools of various kinds. We have always advocated such training where it was kept subsidiary to the ordinary subjects of education, and used as a means of making the instruction real and the knowledge of the students more thorough.

The book we are about to notice shortly is intended to meet the wants of amateurs, and is mainly a reprint of articles which appeared in the *English Mechanic*. Its object is to supply, in a simple and concise manner, information respecting the principles of construction and modes of operation of engineers' machines and tools, and hints respecting the judicious use of the same, and it seems well arranged to meet this object. It is divided into two parts, in the first of which the uses of the ordinary machines found in small establishments are explained, and, in the second, of the more common hand tools. The majority of amateur workshops will not be supplied with any of the ordinary prime movers, but in order to meet the wants of those of larger size some useful hints are given in the first chapter about the working of small steam and gas engines. Then follows a description of lathes suitable for amateurs, of lathe chucks, drilling machines, shapers and planers, circular and band saws. The value of the description is in some cases increased by sufficient details and dimensions being given to enable skilful amateurs to construct these things for themselves. A short description is given of a small smithy and brass foundry, and of the apparatus required, so that those who are able to have such departments may have a fair idea of the best method of arranging them. There are two chapters on a considerable number of miscellaneous appliances, but the most of these are only likely to be wanted by those who can afford to go in for considerable expense. The second part, treating of the ordinary hand tools, both for working metal and wood, is the one which will be most useful to the majority of amateurs whose space and means are both limited. The principles of cutting tools are clearly explained, and those who study this part of the book should have little difficulty in keeping their tools in good order. The last chapter is taken up with tools for measurement, and gives an explanation of the ordinary rules and scales, as well as gauges and other special appliances for exact measurement, such as micrometer and vernier calipers. The scope of the book does not allow the processes and operations performed by the machines and tools to be described, but the author states that should his present work meet with a favourable reception he may probably devote a companion volume to the subject of handicraft. We hope that this encouragement will not be wanting, as we think the book is well suited for the purposes for which it is intended.

THE JOURNAL OF THE IRON AND STEEL INSTITUTE. No. 1. 1889. London: E. & F. N. SPON.

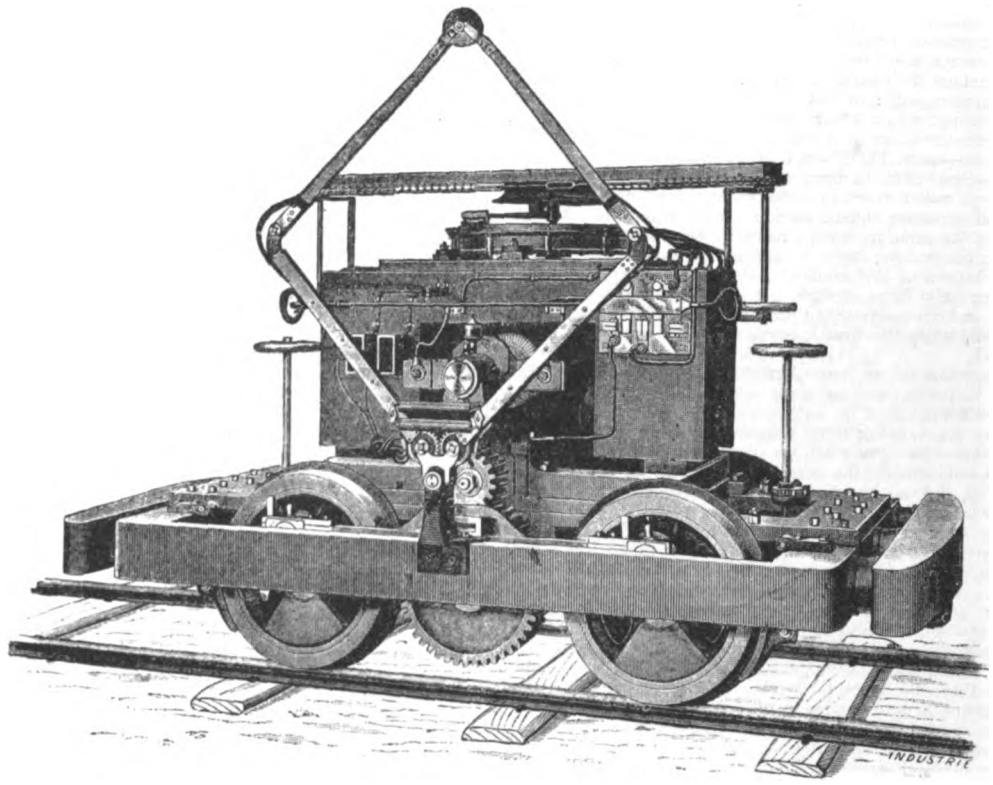
The inaugural address of Sir James Kitson, as President, with which this volume commences, although largely devoted to showing the excellences of Yorkshire iron, will yet be found by steel-makers to contain a fund of information valuable to them. Some idea of the wide ground surveyed may be gathered from the fact that this address is illustrated with twelve plates giving details of the most modern examples of blast furnaces, blowing engines, hydraulic charging apparatus, steam hammers, shearing machines, testing machines, and forging presses. The advantages obtained by the use of modern appliances in industrial operations could not have been better illustrated than by the case of the Consett Plate Mills. Here live rollers are not only used to feed the mill, but to traverse the plates from the roughing to the finishing rolls as well, with the result that the output has been so much increased that they have rolled in one turn 105 tons of marketable plates, equivalent to 1,000 tons per week, where twenty-five years ago 250 tons per week was considered very good work. A somewhat interesting table is given on the subject of steam hammers, that might, at a first glance, reasonably cause apprehension, for whilst England can show nothing heavier that the 35-ton hammer at Woolwich Arsenal, Germany and Russia possess 50-ton hammers, and France heads the list with one of 80 and two of 100 tons. The President, however, reassures us when he adds that the steel forging capacity of England is not represented by a comparison with steam hammer power, and describes the 4,000-ton press of Sir John Brown & Co., which was made by Messrs. Tannett, Walker, & Co., of Leeds. Electrical welding comes in also for a share of attention, and when we are assured that the weld is as strong as the same section in any other part of the bar, we cannot doubt that there is a great future for such a process.

The subject of iron alloys, regarded from a general point of view in the President's address, is treated with special reference to the alloys of nickel and steel in a paper by Mr. Riley. Such remarkable results have been obtained by the addition of nickel to steel, in regard to elongation and tensile strength, not only by the process of M. Marbeau, but also by Mr. J. F. Hall, of Sheffield, independently, that a new era seems to be opening out before the constructive engineer—always provided that the price of the alloy does not prove prohibitive. Mr. Hall tells us that more than a year ago he got 97 tons tensile resistance and over 7 per cent. elongation out of a piece of iron and nickel alloy made by himself. During the discussion Mr. W. H. White asked, "Could engineers and shipbuilders, in dealing with composite riveted structures, depend upon getting rivets which would be workable and trustworthy, and of which the strength

Digitized by Google

should be adequate in proportion to the high tensile strength of plates of the new material that would have to be combined?" This question did not receive a very satisfactory answer, but it is, nevertheless, one to which the makers of these alloys will have to give a practical reply, for, as the strength of a chain is that of its weakest link, so the strength of any riveted structure is frequently only that of its built-up seams.

The valuable paper on the manufacture of basic open-hearth steel, by Mr. J. H. Darby, and that on the progress made in the German iron industry since the year 1880, by Mr. Schroedter, of Düsseldorf, are linked by a common interest, as it is chiefly due to the process named that the great strides referred to have been possible. How valuable the process has proved, and how energetically it has been applied, can be inferred when we read that "the old spoil banks of cinders, which have found an unexpected utilisation for the production of basic pig iron, are almost exhausted, and the supply is now limited to the slag produced in current working." There is no lack of ore, however, as the amount available in the Luxembourg-Lorraine deposit is estimated at 2,400 million tons, which makes it gratifying to learn that the German ironmasters are finding a good trade developing at home at remunerative prices. This is said to be in a great measure the result of the expenditure of large sums of money from a common fund to open up new fields for the application of iron, more especially in building construction, as a substitute for stone and wood—a concerted action that may be worthy of imitation amongst ourselves. We must not omit to mention that during the discussion on Mr. Darby's paper Mr. E. Windsor Richards, after explaining his experience with several new forms of furnace, circular and elliptical, remarked: "Why they had all gone away from the rectangular form of furnace of Sir William Siemens he could not for the life of him imagine. However, they had come back to it, and their troubles had pretty well ceased." Mr. Richards considers a large furnace the best, and that it should hold at least 20 tons of steel.



The remaining papers include one "On the Influence of Copper on the Tensile Strength of Iron and Steel," by Dr. Ball and Mr. Wingham, who tell us that the principal effect that the presence of copper appears to exert on iron and steel is to render it extremely hard. With regard to the question of the possibility of producing true alloys of iron and copper, the authors are of opinion that when carbon is present the metal is distinctly far more homogeneous than when no carbon is present. The paper by Mr. Sack, "On Universal Rolling Mills for the Rolling of Girders and Cruciform Sections," is an interesting contribution, although he incorrectly assumes that it is only possible to overcome the difficulties of rolling large girders in steel by means of four rolls as applied in his mill. Such a method was devised by a Mr. Brown many years ago, and consisted in an ingenious arrangement of the grooves in ordinary rolls, the details having been successfully worked out at Landore, where by this means such thin H sections were produced from ingot metal that they were the admiration of all engineers who saw them. M. Pourcel's contribution, "On the Application of Thermal Chemistry to Metallurgical Reactions," is an attempt to introduce into the field of practice an instrument which "is not as yet of such a character as to have a direct bearing upon most studies of chemical phenomena." That the manufacture of iron and steel offers scope for its application cannot, however, be doubted, and M. Pourcel's effort merits commendation, for, as he says, "If thermal chemistry is still poor in results, work should be done with a view to add to their number, and not to question their value." The last paper is one by M. Gautier, "On the Thomasset Testing Machine," which, with the discussion that followed its reading, constitutes a valuable addition to the literature of a subject of great importance to the manufacturer as well as to the engineer who has to use iron and steel in his structures. A series of communications is thus brought to a close which is quite up to the high standard of those reported in former volumes.

ELECTRIC LOCOMOTIVE FOR MINES.

We illustrate above an electric locomotive for mines which has recently been built by the Thomson-Houston Electric Company for the Hillside Coal Company, Scranton, Pennsylvania. The wheels are 3ft. gauge, and the dimensions are: Length, 9ft. 7in.; breadth, 5ft. 3in.; height, 5ft. 6in. The weight is 4½ tons, and the maximum speed is 6·2 miles per hour. The electromotor is capable of supplying 40 h.p. Suitable resistances are placed upon the machine for the purposes of regulation. The current is collected by a lazy-tongs apparatus from an overhead wire, and the return current is carried along the rail.

ELECTRIC LOCOMOTIVE FOR MINES.

CONSTRUCTED BY THE THOMSON-HOUSTON ELECTRIC COMPANY, LYNN, MASSACHUSETTS, U.S.A.

THE INSTITUTION OF ELECTRICAL ENGINEERS.

At a meeting of this Institution, held on the 20th inst., a paper was read on "Some Points in Dynamo and Motor Design," by Mr. W. B. Esson. We give a short abstract of the paper as follows:—

1. MAGNETISING FORCE FOR A SIMPLE MAGNETIC CIRCUIT.—The formula of Drs. J. and E. Hopkinson is now adopted by most designers who desire to economise their time. Reduced to ampere-turns, this formula for the magnetising force is—

$$A_1 = L\,f\left(\frac{N}{a}\right) + L_1 \cdot 8\frac{r_1 N}{a_1} + L_2\,f\left(\frac{r_2 N}{a_2}\right) + L_3\,f\left(\frac{r_2 N}{a_3}\right) + \ldots$$

Here A_1 is the magnetising force; L, L_1, L_2, and L_3 are the mean lengths, in centimetres, of the separate parts which constitute the magnetic circuit—comprising in this case armature core, air gaps, magnet limbs, and yoke—while a, a_1, a_2, and a_3 are the cross sections, in square centimetres, of these several constituents. Of the induction produced in the magnet cores, only the portion N, which passes through the armature and is enclosed by the coils at the brushes, is serviceable. In the above expression r_2 is the ratio of the induction in the magnets to that in the armature, the total lines induced being therefore r_2 N. The functions $f\left(\frac{N}{a}\right)$, $f\left(\frac{r_2 N}{a_2}\right)$, &c., are read directly off curves found experimentally.

2. MAGNITUDE OF THE STRAY FIELD.—In order to employ the expression in 1 we require to know the stray field. The value of r_2 in different types of machines depends not only on the shape of the magnetic system, but on the position of adjacent masses of iron in bed-plates, bearing brackets, fly-wheel, &c. It must be remembered that no two machines of the same type have exactly the same value of r_2 unless their dimensions correspond in every particular. The values of r_2 have been ascertained for the following machines, and probably for all modern types they lie between these limits.

Stray Field in Different Dynamos.

Name of Machine.	Field.	Armature.	Remarks.	Value of r_2.
Edison-Hopkinson	Single Magnet, 2-pole	Drum	Poles next bed-plate	1·32
Siemens	Single Magnet, 2-pole	Drum	Yoke next bed-plate	1·30
Phœnix	Single Magnet, 2-pole	Cylinder	Yoke next bed-plate	1·32
Phœnix	Double Magnet, 2-pole	Cylinder	Horizontal	1·40
Manchester	Double Magnet, 2-pole	Cylinder	Bed and one pole cast together	1·49
Victoria	Double Magnet, 4-pole	Ring	Ordinary pattern	1·40
Ferranti	Double Magnet, multipolar	Coreless Disc	Ordinary pattern (alternating)	2·00

When the linear dimensions of a machine are increased in the same proportion, r_2 remains approximately unaltered. As only a small portion of the magnetising force is needed for the magnets an error in the determination of r_2 makes very little difference in the resulting machine. In practice differences in the quality of the iron lead to much greater errors than are likely to arise from an error in the estimation of the stray field.

3. SYMMETRY OF THE FIELD.—It is of some importance to obtain a symmetrical field through the armature, as it is only when the field is symmetrical that the armature is electrically and magnetically balanced. The pole pieces should not be thinned down, else there is an upward force which lifts the armature and heats the bearings. In well-designed machines of the single-magnet type there need be no trouble, however, from magnetic pull on the armature. The magnetic pull may be balanced by the very simple device of placing the armature eccentrically in the field, as I suggested two years ago. In cylinder-wound armatures not only is there a want of magnetic balance when the field is unsymmetrical, but there is a want of *electrical* balance, and it becomes, in consequence, doubly important to get a symmetrical induction. Though the lines were unequally divided there might not be any appreciable difference in the e.m.f.'s generated in each half with the brushes diametrically opposite; but from the fact that a want of electrical balance requires rather more lead to be given to the brush farther from the yoke, it is possible that the e.m.f.'s in the two halves of the windings may be unequal, the result being a local current round the armature, and consequent waste of power.

There are several methods of obtaining an approximately symmetrical field besides placing the armature eccentrically in the cavity. What we have to do, if possible, is to make the path for the induction through the half of the cylinder core which is farther from the yoke of similar resistance to the path through the nearer half, so that a similar number of lines may flow through each. In the Phœnix dynamo we employ sometimes, with this object in view, a specially designed device. Here the cast-iron magnet has the inside corners cut away, the other top corners being left on. Other modifications on the same principle may be used.

4. RATIO OF ARMATURE SECTION TO FIELD-MAGNET SECTION.—In the early days of dynamo designing the cross section of the armature core in cylinder machines was very small in proportion to that of the field magnets, the copper in the armature was excessive, and the air gap correspondingly great. The result was an induction no greater than in modern machines, but an enormous stray field. In the machines made by my firm six years ago the section of the armature core was about one-third of the section of the magnets, the latter being of wrought iron. I may say these machines anticipated Mr. Swinburne's latest notions, inasmuch as the 14in. armatures of those days were loaded to 25,000 ampere-turns. The first great improvement consisted in doubling the iron and halving the copper, a machine so modified giving about the same output, but with less heating and less sparking, and requiring less magnetising force. We got the same output for two reasons: first, the decreased magnetic resistance resulted in an increased total induction; secondly, of this induction a far higher proportion was utilised. The ratio of the armature section to the magnet section, when modified as above, stood at ·66; but we went much beyond this in increasing the iron in the armature, finding that we obtained for every increase, keeping the air gap the same, an increase in the induction. When Mr. Kapp read his paper here on "Characteristics," I mentioned that then the ratio in our dynamos stood at ·75. Since then we have, in machines for incandescence lighting, returned to ·6. The weight of the armature is only a fraction of the total weight of the machine. The field magnets are

Digitized by Google

many times heavier, but, besides these, the bed-plate, bearings, &c., make up a large portion of the weight; and since the weight of neither magnets nor bed-plate is increased by an increased armature section, manifestly, if a large output for the weight is the object, and if nothing occurred to interfere with the process, the cross section ought to be increased to such dimensions that for any further increase to the total weight of the machine we get no corresponding advantage. Pressing the induction up to high values is not advisable, as the magnetism then costs too much. Everything considered, 17,000 per square centimetre is probably the best degree of saturation to employ for cylinder armatures, and makers who once employed a greater induction are, I believe, coming down to this. If we work lower we get on the bend of the curve, or on that part where the angle changes rapidly; so that it is not possible to obtain in compound machines with a lower induction such perfect regulation. In four-pole machines it is usual to saturate the armature to a lower degree—about 14,000—and in alternators the induction is still less—about 6,000. In drum machines the induction per square centimetre is rather over half of the value given for cylinders, and the ratio of armature to field section varies from ·8 to 1·0. The diameter of the armature being fixed with reference to the number and size of conductors, there is nothing to be gained by cutting away the interior of the washers. On the contrary, by cutting an opening only large enough for the shaft, the induction is kept low, and the magnetising force for the armature correspondingly small, while the heat generated due to hysteresis is also diminished.

5. Interference of the Armature Field.—Though iron may vary in quality, and so upset occasionally our calculations, no great difficulty need be experienced in approximating pretty closely the magnetising force required for a given induction in the armature core. But when we allow a current to flow in the coils, and so magnetise the core, we superpose on the original a second field, and the interference between them renders the case no longer simple.

6. The Effect of Distortion on the E.M.F.—The distortion of the field produces in a dynamo run without lead a diminution in the e.m.f. for two reasons—first, because the induction acts differentially on the conductors lying between the brushes; secondly, because the currents flowing in sections active when short-circuited under the brushes weaken the field. These local currents induce lines in the opposite direction to the forward induction. Let the machine run as a motor in the opposite direction, the currents flowing through the field magnets and armature being of course in the same direction. The e.m.f. is induced in the armature in the opposite direction, and since in an active coil short-circuited under the brushes the current will flow in the direction of the induced e.m.f., its effect will be to directly strengthen the field as it increases the forward induction. We may say, then, that the effect of distortion is to diminish the e.m.f. in a dynamo run without lead, and increase it in a motor, owing to the local currents generated in the short-circuited coils. The difference in the e.m.f. of a machine run without lead as dynamo and motor may be considerable, as shown by Professor Ayrton's experiments at the beginning of last year.

7. Position of the Brushes in Dynamos and Motors.—If dynamos are to run sparklessly there must be a lead given to the brushes. When a section is short-circuited under the brush any lines of force which were induced, due to the current flowing in it, are annihilated, the current tending by self-induction to continue in the same direction round the short-circuit. The e.m.f. of self-induction depends, obviously, upon the variation in the number of lines through the section which the cessation of the current is capable of producing, on the speed of the armature, and on the number of turns per section. When an armature core is saturated at 17,000 per square centimetre it will be realised that the variation in the lines through the section which the short-circuiting is capable of producing is very small—in fact, practically negligeable. The brush must be placed in advance of the neutral point: in an armature, for instance, having 50 sections, presuming that 5 volts are wasted in the armature, a section when it leaves the brush must move in a field having such strength as will neutralise the effect of self-induction and give one-fifth of a volt over. If the armature has 100 sections the field must give a resultant of one-tenth of a volt, but the e.m.f. due to self-induction will be in the latter case only one-fourth of what it was in the former. By saturating the core and making the sections sufficiently numerous we can make the self-induction as small as we please. We see, then, that in a dynamo the brushes must be set in advance of the neutral point, and that self-induction increases the lead. Is the trail in a motor similarly increased? It is. It appears that the best position for the brushes in a motor is the position in which they have about the same trail as they have lead when the machine works as a dynamo, and that in a motor the trail is *increased* by self-induction.

8. The Load to be Carried by Armatures.—Assuming that a machine is properly designed, a position can be found for the brushes where the sparking is *nil*. If, on the other hand, the machine is badly designed, or if the current carried by the armature is too great, a sparkless collection will be found impossible, from the excessive distortion produced by the armature field. The cross induction depends on the width of the air gap; for the greater the cross section of the gap, the greater the cross induction for a given cross section of armature core and a given magnetising force. It depends also, but to a less extent, on the induction in the core. The forward induction we can give to a machine may be considered as proportional to the cross section of the armature core. Now the distortion of the field depends upon the ratio of the cross to the forward induction. The cross induction is proportional to the ampere-turns on the armature and to the width of the poles, measured parallel to the direction of rotation, and inversely proportional to the length of the air gap. Inserting what appears to be the mean value, we have for the ampere turns which may be carried by an armature the expression,

$$A_2 = \frac{r\,/\,85{,}000}{w}.$$

9. Magnetising Force Required to Compensate the Backward Induction.—The weakening of the field by the current flowing in armatures wound on the von Hefner-Alteneck principle has been studied by Drs. J. and E. Hopkinson; but from the fact that the lead upon which the weakening depends is in Gramme-wound armatures much greater, and to a large extent indeterminate, it follows that, in designing, some approximate rule must be employed to fit the types of machines in which these are employed. I have met with some very curious rules for determining the compensating turns. These generally take the form of adding to the magnetising force determined for the required induction at full load such additional ampere-turns as will increase the induction about 5 per cent. It is assumed that at full load the e.m.f. will be as desired, the 5 per cent. extra being for compensation.

10. Total Magnetising Force.—To the magnetising force required for a simple magnetic circuit as given in 1, we have to add the force required to compensate the backward induction, as given above. If the series coils are connected in series, to get the number of compensating turns on each horse-shoe we have only to multiply the external conductors on the armature by ·165.

11. Working Temperature.—The ultimate rise in temperature of coils wound with double-cotton-covered wire varnished on the exterior is, approximately in degrees centigrade,

$$C^\circ = \frac{W\ 355}{S},$$

where W is the rate at which energy is dissipated in watts, and S the cooling surface in square centimetres. If for the latter we substitute square inches, S_1, the equation is

$$C^\circ = \frac{W\ 55}{S_1}.$$

The coefficients have been obtained from practice, but they are liable to some uncertainty. For armatures—which in rotating induce a current of air—the equation is different, and the coefficient given above may have a much lower value, according to the velocity and ventilation. For armatures the surface velocity of which is 50ft. per second (3,000ft. per minute), and the exterior diameter of the core 1½ times the interior, the length being about equal to the diameter, the rise is, approximately,

$$C^\circ = \frac{W\ 225}{S},$$

or

$$C^\circ = \frac{W\ 35}{S_1},$$

acordingly as the surface is taken in square centimetres or square inches. Here the whole of the cooling surface inside, outside, and at the ends is counted, W being the total watts dissipated in both electrical waste and hysteresis. The latter must, under no circumstances, be neglected, as it may reach 20 per cent. or more of the total. Considerable difference of opinion exists with reference to the temperature rise which should be permitted in dynamos. The rise of about 11° C. allowed by the Admiralty is admitted by all engineers to be absurdly low, while, on the other hand, the machines sent out by some manufacturers get at their normal output dangerously near the temperature at which the insulating material would become useless. In my opinion, an ultimate temperature of from 70° to 75° C. may be permitted with perfect safety, but this should not be exceeded. Independently of the ultimate temperature, the rise in working should not be too great, and accordingly we have in the Phœnix dynamo fixed this limit at from 30° to 35° C. For armatures having the proportion stated, the surface requires to be about 7·3 square centimetres (1·13 square inches) per watt, but here it is less easy to formulate rules. The temperature of the surfaces does not measure the temperature of the bottom layers of wire or of the armature core itself, and when I speak of a temperature of 70° C., I mean, of course, that of the hottest part. Of course it will be understood that the coefficient given for the rise of temperature will be greater for those armatures in which the central opening in the core is less than two-thirds of its external diameter.

12. The Best Relation between the Iron and Copper in the Armature.—Suppose we have a cylinder armature of certain radial depth over the winding: while keeping this depth the same, we may vary the iron and copper of which it consists within wide limits. The question is, what relation of copper to iron will give the best results, premising that, however the relation is varied, the temperature shall remain the same. The cooling surface we will take to be unaltered, and this means, neglecting hysteresis, that the heat generated in the winding shall be constant. Since the waste is constant, the point of maximum coincides with that of maximum output. If the copper on the outside of the armature is considered as a shell of t thickness, we may, within the limits of our inquiry, take the current that may be carried to generate the same heat $= \sqrt{t}$. The e.m.f. produced will be proportional to the radial depth of the armature core, a, and assuming in each case the same degree of saturation, the greatest output for a given radial depth of armature is obtained when $a\sqrt{t}$ is a maximum. This occurs when the exterior layer of copper is about one-fourth the depth of the armature core. It may be assumed, without any great error, that the weight per unit length of circumference is constant, however the proportions vary. With a square or bar winding this is about correct. Machines are not always designed so that the proportions give maximum output, since other considerations arise besides that of the best result from the armature considered by itself. The question of magnetising the core has to receive attention, and the question is resolved into, What is the best proportion for the machine, considered as a whole? The answer to this depends entirely upon the design. For drum armatures the relation for maximum output can be similarly determined, and similar conditions fix the limit of departure from the maximum. One point with reference to these considerations should be noticed, and that is, that neither for cylinders nor drums does the point of maximum efficiency or output coincide with the point at which watts/weight of copper or volts/yards of copper is a maximum, and that these ratios, as applied to compare the performance of dynamos, are accordingly misleading. Given a limiting temperature, the only factors upon which the commercial value of machines should be based are cost and commercial efficiency. Whether the magnets shall be made of wrought or cast iron, whether there shall be a large amount of copper or a small amount, are questions for the manufacturer to decide. In some cases it may pay him to increase the copper and use cast iron, in other cases diminish the copper and use wrought iron. But the finished product is to be judged by its cost to purchase and its cost to run.

13. Motor Designing.—As a general rule, the question of weight does not enter into dynamo designing, except in so far as cost is affected, and a lighter machine means a somewhat increased cost for the output. But in motors it is sometimes necessary to keep the weight as low as possible, and the point to be emphasised here is that in designing light-weight motors we proceed upon lines precisely similar to those adopted in designing light-weight dynamos. It has been asserted that in motors the armatures ought to be larger compared with the field magnets than in dynamos; and by "larger" must be meant either that the armature cross section is greater, or that the ampere-turns on it are more numerous. As regards the former, it has been shown in Section 4 to what extent the relation between the cross sections of the armature and fields influences the dynamo, and the same reasoning applies to motors; as regards the latter, curiously enough, some examples show no overloading, but about the same number of ampere-turns is carried as by dynamo armatures—a fact which does not favour the "large armature" school.

14. Constant-Potential Motors.—Now as regards another thing which we have been told sometimes—that the armature and magnet fields are added in a motor—so far is this from being the case, that, under the usual and proper conditions of a trail on the brushes, the weakening of the field due to the current in the armature may play a most important part in the governing of motors at constant speed. In an article contributed to the *Electrician* in 1886, I hinted at this, saying, "By reason of the current in the armature reacting to weaken the field, does not a shunt motor contain within itself the germ of self-regulation, which, by suitable proportion, may be made effective without a series coil at all?" Since that date motors have been constructed in which the truth so foreshadowed has been realised. It must not be thought that because a motor transmits power it is necessary to manipulate electro-mechanical equivalents until we get torque in pound-feet or foot-pounds per revolution, or some other mechanical quantities. This is only a waste of time. In designing a motor, we know the horse-power or watts to be given off on the brake at a certain speed, and if we make the machine run at the proper number of revolutions, and in accordance with the conditions of electrical supply, the torque will come out all right without our troubling about it.

15. Constant-Current Dynamos.—There seems to be an impression that dynamos for high differences of potentials cannot be worked successfully with Gramme commutators; the reason for this opinion being, I suppose, the breakdown of some imperfectly constructed machines. That there is no difficulty with the insulation between the conductors and armature core is obvious from the fact that high-potential alternating-current machines are working successfully with armature sections similarly disposed; the fault appears, therefore, to have been solely with the commutators. I need only reiterate the remark I made here a short time ago—that there is no difficulty whatever in constructing Gramme machines up to 1,000, 1,500, or even 2,000 volts, provided the designer knows what he is about. Several attempts have been made to compound machines for constant current, all of them uniformly unsuccessful. It is beginning to be realised that—Deprez notwithstanding—it cannot be accomplished, and during the next six years the equations for constant-current compound winding may finally disappear from our text-books. But it may take longer.

MAGNETIC PHENOMENA.

On Friday evening, the 21st inst., Mr. Shelford Bidwell delivered a lecture at the Royal Institution, on "Magnetic Phenomena."

After some general introductory remarks on the nature of magnetic phenomena, and on Faraday's conception of "lines of magnetic force," the lecturer called attention to a very delicate reflecting magnetometer, consisting of a small magnet attached to a suspended mirror, the deflections of which were made visible to the audience by means of a lamp and scale in the usual manner. He then proceeded to show that various small iron objects, such as a pocket knife, a nail, and a door key, none of which had been intentionally magnetised, nevertheless exhibited traces of magnetism. The well-known experiment, illustrating the earth's power of magnetic induction, consisting in holding a bar of soft iron in a vertical position and observing its polarity, then inverting it and tapping it, on which its polarity is reversed, was very well shown by the magnetometer, a very light tap being sufficient for the purpose. A soft iron bar, which had previously been deprived of its magnetism by raising it to a yellow heat, and allowing it to cool in an east and west direction, and therefore with its length perpendicular to the earth's lines of force, was then moved parallel to itself into the neighbourhood of the magnetometer without producing any sensible effect, but a deflection was immediately visible when the bar was turned into a vertical position, the direction of the deflection showing that the lower end had become a north pole.

The lecturer next proceeded to give a brief account of Joule's experiments demonstrating the elongation of iron bars when magnetised, and described the apparatus which he had himself employed when, in the year 1885, he had extended Joule's observations by the investigation of the behaviour of iron bars under much more intense magnetic fields than those employed by Joule. The field was produced in the interior of a vertical coil traversed by an electric current, and the bar to be experimented on was placed in the axis of this coil. The lower end of the bar was fixed, and upon its upper end rested the extremity of the long arm of a lever turning about a horizontal axis, and carrying at the end of its shorter arm a mirror, the motion of which was

Digitized by Google

read on a scale at a distance of 21ft. This apparatus was so delicate that an elongation of one twenty-five millionth of an inch could be detected. These researches, and subsequent ones made by Professor Ewing, had shown that while in the case of iron elongation took place in magnetic fields of an intensity less than a certain value between 200 and 300 C.G.S. units, as the strength of the field increased beyond this limit contraction began to occur of an amount gradually increasing until the strength of the field somewhat exceeded 1,000 C.G.S. units, after which there appeared to be no further change in the amount of the contraction. The lecturer stated that Professor Barrett had discovered that nickel did not elongate like iron, but began at once to contract with considerable rapidity, gradually diminishing as the strength of the field increased, until ultimately no further contraction appeared to take place. The behaviour of cobalt was exactly the reverse of that of iron—viz., it first contracted, and then became elongated as the strength of the magnetic field was increased.

Great difficulty was experienced in making these experiments owing to the effect of change of temperature, the elongation produced in an iron bar by a rise of a degree in temperature being about twenty times as great as the maximum magnetic elongation.

This was illustrated by means of an apparatus of the nature previously described, in which a motion of the spot of light over an inch of the scale corresponded to an elongation of three-millionths of an inch in the bar, the spot being made to move rapidly along the scale by simply holding the hand near the bar.

The lecturer stated that he had succeeded so far in overcoming this difficulty, that he had obtained results which could be relied on to within at least one three-millionth of an inch.

The lecture was brought to a conclusion by the exhibition of some specimens of Dr. Hopkinson's alloy of iron with 25 per cent. of nickel, some in their natural state, and others which had been cooled in frozen carbonic acid gas. The former were shown to be non-magnetic, while the latter were so strongly magnetic that a moderately heavy specimen was easily lifted by a small horseshoe magnet.

THE PHYSICAL SOCIETY.

At a meeting of this Society, on the 21st inst., Mr. F. B. Hawes read a communication "On a Carbon Deposit in a Blake Telephone Transmitter." The author exhibited photographs of the interior portions of the transmitter on which the deposit had taken place. These portions consist of a metal diaphragm, a highly-polished carbon button, and a platinum contact piece carried by a German silver spring placed between them. The diaphragm presented a mottled appearance due to the deposit, but the part which had been behind the German silver spring seemed comparatively clean. The deposits on the carbon button and German silver spring were much less dense than that on the exposed parts of the diaphragm, and the space near the point of contact between the platinum and carbon was free from deposit. The deposit was fairly adherent, considerable rubbing being necessary to remove it, and on examination under the microscope particles of copper and metallic crystals could be seen. The author believes the deposit due to some kind of bombardment of carbon particles, but was unable to say why it should occur, or why the varnished diaphragm should receive the greater deposit, although it was further from the carbon than the German silver spring.

Mr. C. V. Boys said the photographs reminded him of a phenomenon he observed some time ago on a glass sheet, against which one terminal of a dry pile had been resting for some weeks. Just as on the carbon button, the glass near the point of contact was clean, and had a comet-shaped deposit formed around it. He could offer no explanation of the appearance.

A communication was then read on "The Geometrical Construction of Direct Reading Scales for Reflecting Galvanometers," by Mr. A. P. Trotter. In a recent paper "On Galvanometers," by Professor W. E. Ayrton, F.R.S., T. Mather, and Dr. W. E. Sumpner, read before the Society, the opinion was expressed that proportionality of scale reading to current was very desirable, and the present paper shows how to bend a scale of equal divisions so as to give the required proportionality. Suppose the currents required to produce several deflections have been experimentally determined; a full-size plan of the scale is then drawn, and radial lines from the points on the scale at which the observations were taken are drawn towards the centre of the mirror. Let these radii be numbered 0, 1, 2, 3, &c., commencing from zero azimuth. According to the procedure recommended, distances proportional to the several current strengths are marked off along the edge of a strip of paper, a few inches being left over at each end. Call the marks a, b, c, d, &c., a being the zero point. Two points on the radii, 0, 1, and equidistant from the mirror, are now found such that the distance between them is equal to that between a and b on the strip, and the points marked by fine needles stuck in the board. The zero end of the strip is now fixed so that the marks a and b lie against the needles, and the strip is swept round until the mark c coincides with the radius 2, where also a needle is placed. Repeating the process gives a series of points which, on being joined, form part of a polygon. A line can then be drawn between the inscribed and circumscribing curves, which has the same length as the sum of the straight lines, and this is the curve to which the original scale may be bent so as to give proportional readings. Diagrams, showing such curves, constructed from the calibrations of instruments given in the paper above referred to, accompanied the paper. The author showed that a family of curves may be drawn, each of which satisfies the required condition. Of the two limiting curves, one is tangential to the usual scale line at zero azimuth, and the other passes through the vertical axis of the mirror. The flattest of the various curves is generally the most convenient.

Mr. J. Swinburne asked whether good definitions could be obtained when such curved scales not equidistant from the mirror were used, and also whether it was not easier to divide a flat scale unequally so that the readings are proportional to the current.

Mr. Trotter, in reply, said Dr. Sumpner thought there would be no difficulty as regards definition with the flat curves shown. He (Mr. Trotter) also added that a curved scale might be advantageous in reading the deflections from one side of a table, as the more distant part of the scale could be more nearly perpendicular to the line of sight. For such an arrangement, however, a parallel beam of light would be required.

Mr. Trotter also read a communication on "A Parallel Motion Suitable for Recording Instruments." This is a modification of Watt's parallel motion, in which the two fixed centres are on the same side of the line described by the "parallel point." The arrangement consists of two vibrator arms, one of which is twice the length of the other, and whose outer ends are jointed respectively to the middle and end of a short lever: the free end of the latter describes an approximate straight line. The motion was arrived at by considering the curve traced out by a point on the radius of a circle such that its distance from the circumference measured towards the centre is equal to the radial intercept between the circle and a tangent line. The equation to the curve is $r = 2 - \sec. \theta$ (conchoid of Nicomedes), and the radius of the osculating circle at the point where the intercept is zero is given as half that of the initial circle. This osculating circle, the author finds, practically coincides with the curve over a considerable angle (40°), and hence may replace this part of the curve; hence the motion.

The author thinks the motion will be useful for recording barometers, ammeters, and voltmeters, as it is more compact than that of Watt, and needs no fixed point beyond the straight path.

THE DETECTION OF WATER-GAS.

The well-known poisonous nature of carbonic oxide has undoubtedly been a hindrance to the progress of water-gas, and as already there have been cases of death attributed to an escape of the gas, it is necessary to provide against any chance of fatality from its use in the future. The danger from this source is considerably augmented from the fact that house piping is often in a very leaky state, and that many of the gas fittings at present manufactured are far from gas-tight. It will be remembered by our readers that Mr. Samson Fox, in the discussion which followed the reading of Sir Lowthian Bell's paper on "Gaseous Fuel" at the meeting of the Iron and Steel Institute last autumn, estimated that 25 per cent. of the amount of the gas bill was owing to the leakages throughout the country. It is therefore of extreme importance that in all cases in which it is proposed to distribute water-gas in any district special attention should be given to the plumbing and fitting of the pipes and connections. Even when this has been carefully attended to, it is difficult to prevent occasional leakage, and the escape from an open cock might cause serious results. It has been proposed that where water-gas is employed in dwelling-houses for heating or lighting purposes it should be rendered odorous by passing it through some volatile liquid having a characteristic and penetrating smell, the vapour of which being present in the gas would at once give warning on any escape taking place. Many liquids have been proposed for this purpose, but unfortunately most of those with strong odours are likewise so unpleasant that their use is attended with many objections. Some of the volatile organic sulphur compounds—*e.g.*, mercaptan—have been tried, but the persistent nature of their odour is such that, even when the gas-fittings are thoroughly tight, the momentary escape of the unburnt gas when the stopcock is first opened before lighting is sufficient to scent the room for a considerable time. This difficulty can, however, be overcome by using those burners in which the gas is kept continually alight. Sulphur compounds are, however, undesirable on other grounds, as the products of combustion of unpurified coal-gas have a very injurious effect upon health, metal work, and paints. Of all the liquids which have been produced for thus rendering water-gas odorous pyridine is probably the best, as its odour is by no means so objectionable as that of many of the organic sulphur compounds, and, as it contains no sulphur, the gaseous products formed by its combustion are free from any deleterious qualities.

Besides these methods for detecting the escape of water-gas based on the use of volatile odorous liquids, Rasine has recently devised an ingenious carbonic oxide detector constructed on an entirely different principle. Platinum black, as is well known, has the property of absorbing gases in which it is placed, and brings about the union of mixtures of oxygen and combustible gases. The inventor has constructed an apparatus in which this property of platinum black is utilised. It consists essentially of a thread of gun-cotton dusted with platinum black, and so placed that on catching fire it determines the closure of an electric current containing an alarum. He states that the firing of the gun-cotton takes place in air containing 2·5 parts of carbonic oxide per 1,000. It will, therefore, give an indication of the escape when the composition of the air in its neighbourhood reaches this figure. It will require, however, further experiments to be made with this apparatus before it would be safe to rely upon its indications, and we should like to see what influence the simultaneous absorption of hydrogen would have upon its working. It is well known that the blood absorbs carbonic oxide from an atmosphere containing only 0·02 per cent. of the gas, and that with 0·1 per cent. present in the air, half the blood of an animal becomes poisoned, so that the apparatus in its present form will not prevent such slow poisoning. It may be that the platinum black absorbs carbon monoxide from a gas containing a lower percentage than 0·25, and that if time be given the accumulation of carbonic oxide in this way will be sufficient to determine the firing of the cotton thread. With the exception of this thread, the apparatus is of a permanent nature, and will, therefore, be easy to keep in order. The two metallic plates which close the circuit are so arranged that one is immediately above the other. This upper plate is held in position by the combustible thread, and is also connected by a bent rod to a lever, which thus prevents the plate from being displaced.

THE OUTLOOK IN THE SALT TRADE.

Our Cheshire salt industry has not yielded very satisfactory returns for the business of the last year. The statistics show that there has been a marked decrease in the export trade since the operations of the Salt Union have influenced the market. The quantity exported during the year only reached a total of 745,111 tons, as compared with 1,022,334 tons in 1888, and 994,726 tons in 1887. This falling off is, no doubt, mainly to be attributed to the increased price for export salt demanded by the Salt Union, which has naturally driven our foreign buyers to other countries and to develop their own local resources. It would be interesting to compare the dividends of the salt companies before the amalgamation with the 10 per cent. recently declared by the Union. The most marked decline is, however, noticeable in our colonial trade, especially in that with India. The quantity shipped to Calcutta has diminished from 314,332 tons in 1888 to 221,616 tons for the present year. Other diminished exports are those to Canada, which was 15,000 tons less than in 1888, and to the United States, which has fallen off to the extent of 25,000 tons. Recent trade advices seem, however, to point to a more active demand in the Mersey district, which may indicate a revival of the industry, and that these statistics for 1889 only denote a temporary depression in the export trade. In the Tees-side district most of the larger salt producers have been extending their works, and other schemes for increasing the produce of the salt beds are being projected. The Durham deposits lie at a much greater depth than those of Cheshire, and present more difficulties for successful working. The New Durham Salt Company, at their recent meeting at Leeds, were furnished by a report to the effect that the company's borings had not yet succeeded in reaching the requisite depth for obtaining a remunerative brine. For the encouragement of the Tees-side industry, the building of a railway from Stockton to Port

Digitized by Google

Clarence is contemplated, which, when completed, together with the increased facilities on the Tees, will no doubt considerably augment the export trade from this district. Last year the output from this locality was upwards of 200,000 tons, and the price at the close of the year was only about 1s. over the current price in December, 1888. The rise in price of salt has not been proportional to the increase in the value of the coal, which has nearly doubled during the same period, as several of the Cleveland saltmasters are able to disregard the state of the coal market through their furnaces being driven by waste heat from the blast furnaces. The total production in Europe is estimated at about 3,000,000 tons, of which more than two-thirds was supplied from Great Britain, and about 750,000 tons, or one-third of the production, is consumed by British metallurgists and chemical manufacturers.

THE TRADE IN NITRATE.

THE trade in South American nitrate has developed in a marvellous degree in recent years, and in order still further to extend it the Chilian President in his message has intimated that the executive has in view the establishment of a system of propaganda for the purpose of opening up new markets for nitrate in Asia and America, as well as in Europe. To this effect agents will be sent to the various countries with the object of making known this fertiliser, by means of publications and experiments on the land. These agents will be under the superintendence of a central committee established in Europe, and composed of persons, who, from their knowledge of fertilisers, and their scientific and industrial position, will be fitted to fulfil the office successfully and zealously. This committee will collect the most complete statistics with regard to the land susceptible of cultivation in the various countries and the nature of the fertilisers employed on it; will carry out experiments with the object of demonstrating the advantages of nitrate of soda; will set forth the modes of applying it most to be recommended; will publish information regarding the importance of nitrate and the manner of using it; will offer premiums for the best works treating of the advantages offered by nitrate of soda, &c. This is a very elaborate system of pushing trade to be adopted by any Government, and may be justified in the case of one which is largely interested in the industry named, but it is not likely to be adopted by our Government to any extent. We mention it, however, for the purpose of showing how trade in every department is being pushed, and how necessary it is for each one interested in a special department, not only to make himself acquainted with the requirements of his probable customers, but also to make them aware of the properties of his goods.

Notes.

MINERALS IN CANADA.

THE Geological and Natural History Survey of Canada has issued the annual report for 1888, on mines and minerals, from which it appears that the total value of the production was $16,500,000. The principal item is coal, of which 2,658,134 of the value of $2,259,832 at the pit's mouth, was obtained. About four-fifths of this output was from Nova Scotia. There were 61,310 ounces of gold produced, of the value of $1,098,610. The production of iron ore was 78,587 tons, of the value of $152,068.

THE COTTON INDUSTRY.

THE cotton trade, so far as weaving cloth from bought yarns is concerned, continues in a poor condition—that is to say, the demand from the great Eastern markets is of an indifferent character, and the margin in most makes is unremunerative. This state of affairs has led to looms in many sheds being allowed to stand idle, and, further, employers have not kept their machinery running at full stretch. It would appear that the present rate of production of cloth is too large for the requirements of the various foreign markets. The home trade section of dry goods keeps fairly healthy, most of the distribution channels being, on the whole, busy with the prospects of a good year. Coming now to spinning yarns, as distinct from weaving cloth, the position of affairs has gradually gone worse since the opening of the year. The year opened with cotton nearly ¼d. per lb. lower than Tuesday's rates, and yarn remunerative. This week the margin is little more than change for a shilling, for cotton is at 6d., and coptwist and weft is in sluggish demand at prices that will hardly pay in an old concern. For the reasons previously referred to, yarn is in larger supply, the floating supply between spinners and users being now chiefly in the hands of the former. The probable yield of American cotton this season is still a matter of very diverse views. Messrs. Neill Brothers hold to their original estimate of 7,600,000 bales of 480lb. each, whilst other authorities in Liverpool consider that the total crop will not reach more than 7,250,000 bales. Be the crop what it may, the official figures relating to receipts at the ports and at the plantations are rather in favour of a large output.

CHINESE ENGINEERING LITERATURE.

PERHAPS the first Chinese translation from the English of a technical work on railway and harbour construction consists of eight chapters of Mr. Matheson's "Aid-Book to Engineering Enterprise." The title of the translation would read in English, "Essay on Construction. Englishman Matheson gave the idea. Englishman Fryer and Chang Tien translated it." Printed on fine thin rice paper, from large type, this book is enclosed in loose boards of polished rosewood, held together with silk ribbons, each chapter being separately stitched into a silk cover. The original engravings have been faithfully, though quaintly, reproduced on a larger scale.

THE WEALTH OF THE UNITED STATES.

THE wealth of the United States is increasing with fabulous strides. According to the *New York Herald* its total amount now exceeds the total wealth of the whole world at any time previous to the middle of the eighteenth century, and the amount invested abroad is alone equal to the national wealth of Portugal and Denmark, while the total wealth of five minor nations is only equal to the mere increase of that of the United States in the past nine years. The total wealth of the latter has quadrupled since 1850, and doubled since 1870. There was a decrease in the decade ending 1870, as compared with the previous decade, due to the war, but, with this exception, the increase has gone on by leaps and bounds. In 1889 it had risen to $61,459 000,000.

PROGRESS OF TRADE COMBINATIONS.

IN every department of trade and industry the tendency is towards combination, either in the form of a syndicate or of unions for purposes of protection, and all tend in the direction of monopoly. The latest attempts we have heard of are those connected with the chemical manufacturers who are trying to form a Chemical Union. We are also informed that the makers, or rather refiners, of sulphur are trying to form an association for the purpose of selling the whole product through one broker. Again, at a recent meeting of the cement manufacturers, it was unanimously agreed to form a Cement Union, for the purpose of dealing with such labour questions as may arise in connection with the trade from time to time. These combinations are signs of the times, and must inevitably lead to great changes in economic and industrial conditions.

HOURS OF LABOUR.

AT a time when labour associations, manufacturers, and public men have before them the question of an eight hours day, the reference to this question in Australia in Sir Charles Dilke's new work, "Problems of Greater Britain," comes very opportunely. He states that in most of the Australian colonies the eight hours day for artisans is enforced by general custom, though not by legislation. It was in April, 1856, that the Melbourne stonemasons held the first public meeting on the subject at a time when ten hours a day was the rule for the trade. The other unions followed their example, a meeting of the united trades was held, an eight hours league formed, and notice given that after the 21st April they would only work eight hours a day. The triumph was complete, and a public holiday is still kept in commemoration of the occasion.

JAPAN AND COREA.

IT is rather curious to observe Japan, a country which a quarter of a century ago was practically sealed to foreign trade, now assisting in opening up the only remaining country in the world which is shut to foreigners. But so it is, a new commercial treaty having been signed between Japan and Corea by which an additional port has been opened, and by which the former country gains several advantages. On the other hand, the Coreans have been astute enough to look after their own interests. The whole population of Corea is clad in cotton, and consequently piece goods are the chief articles of import. Formerly Manchester goods entered Corea almost entirely through Japan, where, after paying import duty, they are sent to Corea, paying export duty on leaving Japan and import duty on entering Corea—in all, three duties. In future only one—the Corean—will be payable. The treaty also arranges for the export of various Corean products on paying an export duty of 20 per cent.

AMENDMENT OF THE LIMITED LIABILITY ACTS.

WE have on several occasions pointed out the abuses which take place under the provisions of the Limited Liability Acts, and made suggestions for their improvement. The Manchester Chamber of Commerce seems determined to take up the matter in earnest. At a recent special meeting called to consider the question, Sir W. H. Houlds worth, M.P., suggested that there should be two forms of registration, one provisional and the other complete, and that 75 per cent. of the nominal capital should be subscribed before complete incorporation was granted, with a certain amount paid up. He thought, moreover, that care should be taken to see that the balance sheet showed the depreciation taken off each year. In order to prevent the floating of bogus concerns, the subscribers to the original memorandum should be compelled to take a substantial interest in the concern. These proposals seem reasonable and not at all likely to hinder any *bonâ-fide* concern from being floated, and we trust that this matter will be taken up with vigour, and a Bill pushed through Parliament as quickly as possible, so that legitimate enterprise may be encouraged, and mere speculation discouraged.

ELECTROLYTIC WHITE LEAD.

THE *Electrical World* has recently given an outline of a process for the electrolytic production of white lead, which has been patented by Mr. T. D Bottome, of Hoosick, New York. The patentee electrolyses a solution containing sodium and ammonium nitrate, which is saturated with carbonic acid gas. The electrodes consist of metallic lead, that forming the anode being oxidised by the nitric acid, and ozone (*sic*) liberated, forming hydrated lead oxide, which combines with the free carbonic acid present in the solution, precipitating the white lead in a fine state of division, and which on drying is ready for use. It will be noticed that carbonic acid, lead, and water are the only materials used up in the process, the original solution of sodium and ammonium nitrate lasting for an indefinite period. The patentee states that the lead dissolves at the rate of 59·82 grains per ampere-hour, forming 71·35 grains of pure white lead. The author's estimates of cost, &c., are, however, written "in American," and are therefore better not reproduced at present. The new material is, of course, found to have much greater covering properties than ordinary white lead.

THE FRENCH NAVY.

SOME time ago we gave details of the proposals for increasing the American Navy, which, if carried out, would give America an unquestioned place in the ranks of the great maritime powers. The French seem determined to keep well up in the race, and Germany is inclined to follow the example. In fact, it looks as if we were going to have almost as much naval as we have military aggrandisement. The following figures show the French programme of naval construction for 1891, and the British one for last year, from which it will be observed that the French have resolved to keep up a large number of torpedo boats, while our programme, when carried out, will give us a strong position as regards cruisers:—

	French.		British.
Ironclads	10	...	10
Cruisers	11	...	42
Torpedo cruisers	2	...	18
Torpedo despatch boats, &c.	8	...	—
Torpedo boats, seagoing	12	...	—
Torpedo boats, first-class	35	...	—
	78		70

These two lists somewhat reflect the characters of the British and the French nations. The former are solid, and believe in ironclads and swift cruisers, while the latter seem to put more faith in light torpedo boats. No doubt the relative numbers are also influenced by the conditions which would arise should either of the nations become involved in war.

Patent Record.

(Compiled from "The Illustrated Official Journal (Patents)."

APPLICATIONS FOR PATENTS.

(The names in italics within parentheses are those of Communicators of Inventions.)

ENGINEERING.

10th February, 1890.

2112. McFerran & Pirrie..... Spinning frames.
2120. Latham, H. W. ..... Machinery for grinding cutlery.
2121. Fox, S. ..... Looms.
2127. Farrar, J. ..... Doubling yarns.
2128. Pollitt & Mangnall ... Reducing valves.
2132. Martin, M. T..... Knitting machines.
2133. Watkins, R. R. ..... Producing rotary motion.
2137. Andersen, L. J..... Sewing machines.
2139. Bellot, O. ..... Heat in furnaces, &c.
2140. Paul, M. J. ..... Discharging coal from lighters to ships or wharves.
2141. Mewburn, J. C. ..... Compressed air supply pipes (*Powell & Kummer*).
2151. Brady, F..... Boring apparatus.

11th February, 1890.

2159. Hodd, F. H..... Railway rails.
2165. Pullan, A. ..... Water gauges.
2175. Rutledge, J. ..... Cultivating land.
2181. Stuart & Binney..... Hydrocarbon engines.
2183. Monie & Rutnagur ..... Carding engines.
2184. Entwistle & Entwistle Carding engines.
2185. Donald, G. G..... Boat-lowering apparatus.
2186. Morris, E. ..... Valve for steam pumps.
2187. Cresswell & Bloom..... Feeding printing machines.
2192. Dunham, G..... Machine for finishing nuts.
2203. Kuba, F. ..... Duplex pump.
2204. Wood, J. J. ..... Journal bearings.
2205. Colas, P. ..... Rotary steam engines.
2206. Reeve, E. D. ..... Washing and drying machinery.
2208. Fraser, J. H. ..... Packing for flanged surfaces.
2216. Shanks, H. H..... Feeding printing machines.
2217. Marshall & FitzGerald Tubulous steam generators.
2218. Marshall & FitzGerald Surface condensers.
2220. Clark, A. M. ..... Lathes (*Zimmermann*).
2221. Carter, H. ..... Excavating machines.
2228. Bruce, L. F. ..... Machine guns.
2229. Wise, W. L..... Pneumatic guns (*Robinson & Reynolds*).
2230. Lake, H. H..... Excavators and elevators (*Smith*).

12th February, 1890.

2247. Jones, J. P. ..... Foot power hammer.
2252. Burgon & Burgon ..... Machinery for shearing sheep.
2254. Heidler, A..... Knitting machines.
2258. Rose, Rose, Rose, & Godman ..... Tool holders.
2274. Wicksteed, C..... Internal roller tube cutters.
2278. The Western Coil and Pipe Cleansing Company by R. W. Applegarth ..... Water coil and pipe cleansing boilers.
2279. Goes, W. ..... Machinery for cleaning metallic sheets.
2280. Millard, W. ..... Printing machines.
2281. Cole, J. C. ..... Crushing and grinding machines.
2284. Higginbottom, J. ..... Machines for reducing grain.
2285. Thompson, W. P. ..... Chain pumps (*Atkinson*).
2287. Haddan, H. J..... Hydrocarbon engines (*Spiel*).
2288. Taylor, J. ..... Coupling for railway waggons.
2290. Barker, W. B. ..... Siren or fog signalling apparatus.
2291. Turner, A..... Anchors.
2292. Brown, A. ..... Elevating ferry steamers.
2295. Schurr, A. E..... Railway couplings.
2301. Allart, L. ..... Wool combing machine.
2304. Davison, R..... Presses for baling hay.
2305. Fabian, P. ..... Friction brake for railway vehicles.
2306. Morris, R. ..... Magazines for rifles.

13th February, 1890.

2314. Jackson, W. M. ..... Pressure gauges.
2315. Sunderland, J. ..... Warp beaming machines.
2316. Ainsworth, J. ..... Looms.
2317. Barbeau, L. E. ..... Grain separator.
2320. Denison, Denison, & Ward ..... Brick-making machines.
2321. Denison, Denison, & Ward ..... Brick-pressing machines.
2334. Robson, J. ..... Motor.
2342. Linkleter, J. ..... Detaching boats.
2343. Wrigley, T. ..... Mechanical stokers.
2349. Metcalfe, T. ..... Slide valves.
2359. Haddan, R. ..... Automatic railroad switches (*Belcher*).
2368. Cottrell & Hancox..... Machinery for grinding knives.
2371. Edwards, C. H. ..... Manufacture of bricks.
2372. Boult, A. J..... Valve (*McNeill & Clarke*).
2373. Fernie, J. H. ..... Looms.
2375. Colley, H. ..... Paper making apparatus.
2376. Boult, A. J..... Seeding machines (*Noron*).
2382. Marsh & Trust ..... Propellers.
2384. De la Touche, W..... Hot-air engines.

14th February, 1890.

2388. Thwaite, B. H. ..... Gas generators.
2390. Buchanan, J., Jun. ..... Gold and silver extraction.
2392. Sumner, H. ..... Governor for engines.
2399. Lodge & Fletcher ..... Stone breakers.
2410. Jackson, I. ..... Elevator buckets.
2416. Guy, C. W. ..... Crushing and leaching mills.
2418. Wood, C. H. ..... Fog signalling apparatus.
2419. Lucas, G. E. ..... Apparatus for placing fog signals on rails.
2423. Wylie, R. P. ..... Raising sunken vessels.
2427. Fryer, A..... Concentration of solutions.
2441. Mackie, J. ..... Driving pulleys.
2456. Desmond, J..... Injectors.
2458. Downton, J. ..... Sewage pump.

15th February, 1890.

2478. Roberts, P..... Metallic packing.
2479. De Mattos, De Mattos, & De Mattos ..... Propelling ships.
2483. Thompson, W. J. ..... Fastening rails to chairs.
2489. Eves, J. V. ..... Frames for spinning flax.
2494. Robinson & Jackson ... Presses for bricks.
2502. Renshaw, W. R..... Heating, cooling, and condensing fluids.

ELECTRICITY.

10th February, 1890.

2113. Schoth, G. A..... Secondary batteries.
2153. Dewar, D. ..... Telephone switchboards.

11th February, 1890.

2172. Boardman, H..... Switch for electric tell-tales.
2199. Currie, S. C. C. ..... Cores and armatures.
2219. Rudolph, H. O. ..... Telegraph printing apparatus.
2234. Nutting, S. E. ..... Electric arc lamps.

12th February, 1890.

2255. Macaulay-Cruikshank, G. ..... Telephonic and telegraphic systems (*Schwabacher*).
2272. Cockburn & Teague ... Operating electric currents.
2273. Postlethwaite, G. R.... Primary batteries.
2296. Richardson & Holland Electrolytic production of caustic soda and potash.
2297. Richardson & Holland Electrolytic apparatus.
2298. Gardiner, S. ..... Electric calls.
2302. Weymersch & McKenzie Electric batteries.

13th February, 1890.

2337. Postlethwaite, G. R. ... Electromagnetic motors.
2347. Forbes, Sir C. S. ..... Primary batteries.
2364. Davis, A. L..... Batteries and glow lamps.

14th February, 1890.

2404. Bathurst, F. ..... Electrical switches.
2439. Roberts, F. S..... Storage batteries.

15th February, 1890.

2464. Dorman & Smith ..... Electric light fittings.
2476. Walton, A. H. ..... Cut-outs.
2496. King & Bickle ..... Electrical conductors.
2503. Saunderson, L..... Electric arc lighting.
2504. Wynne, F. ... . Propelling vehicles by electricity.
2606. Verschave & Baron..... Electric batteries.

CHEMISTRY.

11th February, 1890.

2195. Braithwaite, I..... Dyeing with indigo.
2226. Lebedeff, N. ..... Extracting metals.
2242. Hlawaty, F. ..... Preparing benzol from petroleum.

12th February, 1890.

2248. Harbord, F. W..... Utilisation of tinplate scrap.
2283. Hughes & Gipprich ..... Manufacture of oil gas.
2312. Teague, J. ..... Extracting tin from refuse.

13th February, 1890.

2341. Scudder & Colman ..... Rendering water-gas odorous.

14th February, 1890.

2428. Bowen, S. B. ..... Cleaning grease from tinplates.
2432. Chance & Crowther ... Nitrate of ammonia.

15th February, 1890.

2477. Teague, T. ..... Extraction of tin from slags.
2499. Lake, H. H. ..... Colouring matter (*Oehler*).

MISCELLANEOUS.

11th February, 1890.

2212. Lewis, H. F. W..... Fire alarm telegraphs.

13th February, 1890.

2318. Kenyon, Sen., Kenyon, Jun., Kenyon, & Kenyon ..... Endless driving bands.

14th February, 1890.

2406. Strange & McMahon ... Fire escape.
2411. Ingham, T. ..... Dyeing cotton.
2430. Fenwick, W. ..... Lock nuts.

COMPLETE SPECIFICATIONS ACCEPTED.

Notice is given that all persons interested in opposing the grant of a Patent on any one of the under-mentioned Applications may, at any time within Two Months after the date given, give notice at the Patent Office, in the prescribed form, of such opposition.

Year 1889.

2232. Goodfellow & Sanders.
2457. Daniels.
2462. Jessie Ball.
2561. Pring.
2676. Godden.
2911. Stother.
3119. Wynne.
3236. Bullough.
3279. Hart.
3496. Kaye.
3641. Hughes (*Vaile*).
3701. Brooks.
3781. Franklin.

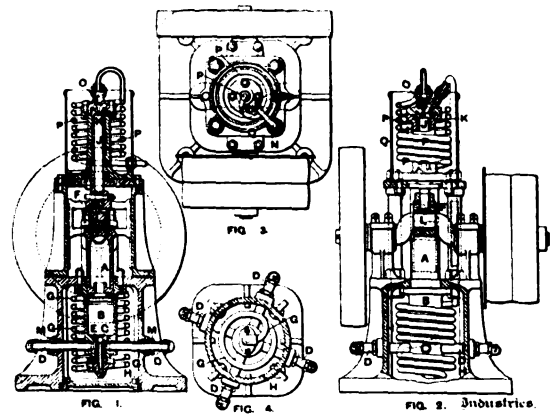
ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.

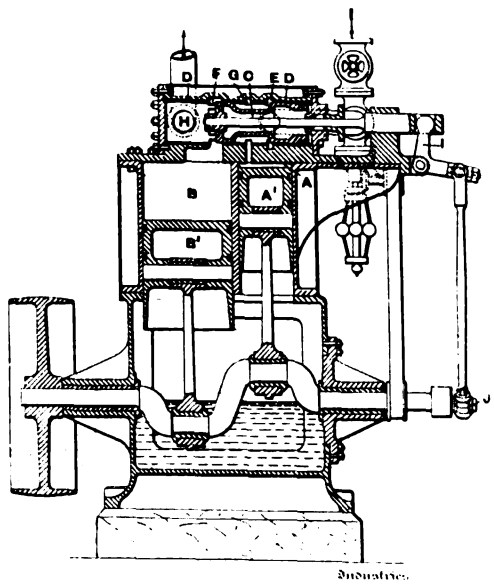
ENGINEERING.

VALVE GEAR OF PUMPING ENGINES.—*J. E. Rogers, Birmingham.*—The valve gear is adaptable to the duplex type of pumping engine, in which the engines are arranged side by side. The piston rod of one engine is made to work the slide valve of the other. Referring to the illustrations, Fig. 1 is a sectional elevation, Fig. 2 sectional end view upon A B, and Fig. 3 a plan of a duplex pump. C C¹ are sliding levers, D D¹ clip joints jointed to the levers by suitable pins and clamped to the piston rods by bolts. The sliding levers pass through the heads G G¹, and have their motion communicated to the cranks H H¹ by the shafts L L¹ to which the cranks and heads are attached. The cranks H H¹ are



connected to the slide valve rods. The dotted lines show position of valve gear at each end of the stroke of each pump. The action of the valve gear is as follows: Suppose the piston rod of one pump to be at one end of the stroke, in moving to the opposite end it carries with it the clip joint D in which is jointed the sliding lever C; this sliding lever C gives a partial rotary movement to the cross shaft L, which moves the crank H sufficiently to give the required motion to the slide valve of the duplicate engine, each engine in turn giving motion to the slide valve of the other through the gear. Claim: The joints D and D¹ in combination with sliding levers C and C¹, sliding lever cross shaft heads G and G¹, cross shafts L and L¹, cranks H and H¹, giving motion to the slide valves through the connecting rods J and J¹ and valve rods M and M¹, substantially as shown and described. —No. 3557. February 28th, 1889. 6*d*.

A PNEUMATIC DISTRIBUTOR.—*A. Wallis, A. H. Wallis, J. E. Wallis, & W. A. Wallis, Basingstoke.*—The machine is provided with hoppers and reservoirs for containing the seeds or liquid to be distributed. A fan is mounted and is geared to the travelling wheels. The air is conducted from the fan by means of a pipe, to which the dry material is fed at any suitable point. On the end of this pipe is fitted a spreading mouthpiece. This mouth is divided where it joins the blast pipe by partitions running longitudinally, and by this means the discharged material is spread abroad. For distributing liquids fine jets are provided, which allow the liquid to fall on the blast a short distance outside the blast mouth, or the jets may be carried on so that they deliver the liquid in the blast a short distance outside the blast. The spreading discharge mouth is attached to the blast pipe at any angle, so that the material can be delivered in any direction. Claims: (1) In a machine for sowing or distributing dry material or liquid by wind blast, the combination of travelling wheels, gearing fan, and blast pipe with a hopper or receptacle for liquid, and with an adjustable mouthpiece arranged as described; and (2) and (3) referring to the parts as illustrated in the specification.—No. 3904. March 6th, 1889. 8*d*.

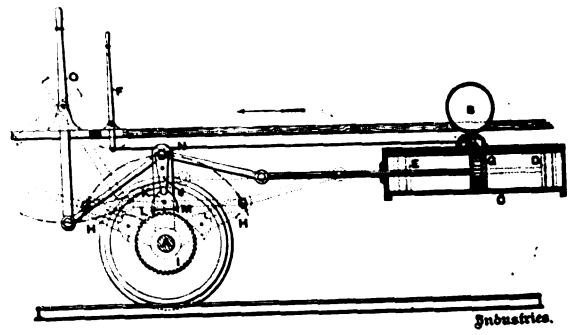


GEAR WHEELS.—*C. Lock, London.*—These wheels are constructed with teeth formed of balls. The balls are located in sockets in the wheel rim, from which they project a distance slightly less than half their diameters, so that they will not drop out of their sockets. The wheel which works in conjunction with the gear wheel described is formed with a series of recesses in its periphery to receive the projecting parts of the balls located in the other wheel, as the wheels revolve. The construction of wheels as described is intended to reduce the friction and form a wheel especially suitable for the driving mechanism of bicycles, &c. Claims: (1) A wheel having a series of balls located in its rim, the said balls projecting sufficiently far to form teeth for gearing with another wheel or with a chain as and for the purpose described; (2) the manufacture and use of gear wheels as described.—No. 4708. March 18th, 1889. 6*d*.

APPARATUS FOR COMPRESSING AIR.—*C. F. H. Hayes, London.*—This system of pumps is designed for compressing air or gases by stages. In the accompanying drawings Fig. 1 represents a sectional side elevation, Fig. 2 a front elevation partly in section, Fig. 3 a plan, and Fig. 4 an under view of the lower part of the apparatus with the base plate removed. The lower cylinder B is fitted with a plunger A, which is connected to the slotted crosshead F driven by the crank L and belt pulleys M. The cylinder

B communicates to the crank suction pipes D by a suction valve C. In the valve C is an exhaust valve E communicating to the coil G in the chamber H. In the top cylinder I is a second plunger J, which is also connected to the crosshead F, and so partakes of its motion. The plunger J works in a sleeve valve K, which is held up by a spring to close the passage N. A valve O is situated at the top of the cylinder I for the exhaust. The working of the appliance is as follows:—The plungers are set in motion, and the lower one A draws in air or other fluid by the pipes D and the valve C. Upon the return stroke of the plunger A the fluid is compressed and forced through the valve E into the coil G, which is surrounded by water in the chamber H. The coil G is connected by a pipe to the passage N, so that as the top plunger J descends the fluid is drawn into the cylinder I, and upon the return stroke it is further compressed and delivered to a second coil P surrounded by water in the vessel Q. Claims: (1) The construction and use of a suction valve having a cavity in its shank or stem containing a delivery or discharge valve in combination with the other parts of a compressing or other apparatus; (2) the construction and use of a valve having a sleeve fitting into but free to move in a cylinder, and itself forming the true cylinder in combination with the other parts of a compressing or other apparatus; (3) the construction and use of a slotted crosshead with a crank passing through it and operating it in combination with a compressing apparatus or force pump.—No. 1424. January 25th, 1889. 8*d*.

STEAM ENGINES.—*R. Kennedy, Kilmarnock.*—This invention refers particularly to the valves and arrangement of ports in compound or duplex single-acting steam engines. In the illustration A and B represent the high and low pressure cylinders, with their pistons A¹ and B¹. Working upon the cover of these cylinders is the slide valve and in the cover are the ports communicating to the cylinders and the valve chamber. The slide valve C is a hollow double piston reciprocating valve, with closed inner end, working within the steam casing D, which is preferably lined. Annular ports E and G are formed in the valve casing D for admitting the live steam to the annular



space surrounding the piston, and from there to high-pressure cylinder. From the high-pressure cylinder the steam is exhausted to the low through the port F, and ultimately exhausted from the low-pressure cylinder by the same port F to the escape pipe H. The valve is actuated by a bell-crank lever I worked by the eccentric J. Claims: (1) The construction or general arrangement and combination of the parts of high speed compound or duplex single-acting steam or other fluid-pressure engines, with their valves and ports and actuating fittings; (2) in compound or duplex single-acting engines the constructing of a double piston reciprocating valve within the steam casing, arranged to admit steam through annular ports to the high-pressure cylinder, and from this to the low-pressure cylinder, and from it to the atmosphere or condenser, and arrangement of mechanism for actuating the same.—No. 3676. March 1st, 1889. 8*d*

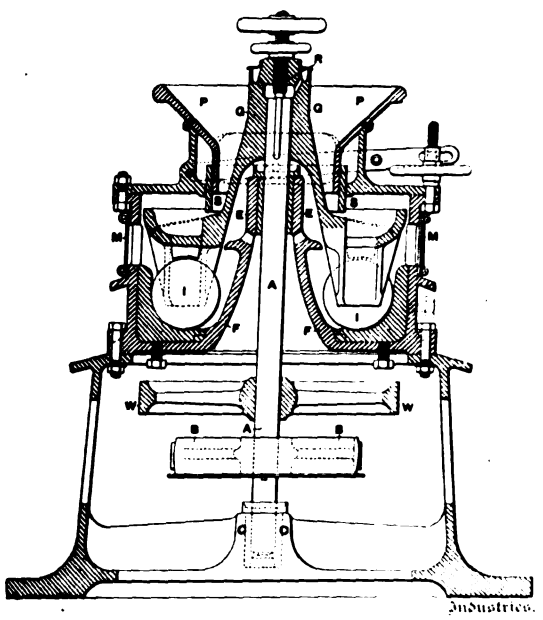
ROCK BORING TOOL.—*E. Salendre, Paris.*—The tool cuts with a rotary and forward motion which is imparted to it by a screwed mandril. The mandril is supported in a long screwed socket which is held in position by a supporting post and chains. The axes of the socket, mandril, and drill are in the same straight line. The mandril is turned by a lever, and as it turns it is screwed out of its socket, so feeding the drill and revolving it. The socket is made in two longitudinal halves which are hinged together, so that by opening them the mandril can be taken out or shifted to any position in its socket. Claim: The boring or drilling apparatus constructed as described.—No. 4471. March 14th, 1889. 6*d*.

SHIPS' ANCHORS.—*W. Rose, Halesowen.*—Instead of making the cross head and arms in one cast piece as is usual, the inventor makes them separately, and of wrought iron. The head is constructed in the shape of a cross, whose shortest arms are slotted to receive the flat head of the anchor's shank, and the longer arms hollowed out to receive a square bolt. The square bolt passes through the long arms with its axis coincident with the axis of the arms, and supports the gripping arms of the anchor at each end and the shank head at its centre. The shank head works in a slot of the cross head and permits the latter to only make a partial revolution as the arms cant over from one position to the other. Twelve claims are made.—No. 3902. March 6th, 1889. 11*d*.

SHIPS.—*A. C. A. Holzapfel, London.*—The ship is built without frames and consists of plates whose sides are flanged inside at a suitable angle. These sides are riveted together, and do not require any frames, keelsons, &c. The system also admits of the use of hydraulic punching and riveting machinery. In building a ship according to this method wooden frames are erected corresponding to the shape of the ship, and the plates are laid inside these frames and riveted in place. Claim: The building of ships or other plated structures of plates flanged on all four sides.—No. 2233. February 7th, 1889. 4*d*.

STARTING VEHICLES.—*E. H. Morgan, Dover.*—This invention relates to means of applying to a vehicle a temporary force for starting it into motion, independent of the force normally applied to keep it in motion. For this purpose compressed air is employed to act upon a piston and give partial rotation to some of the wheels of the vehicle. B is a reservoir of compressed air,

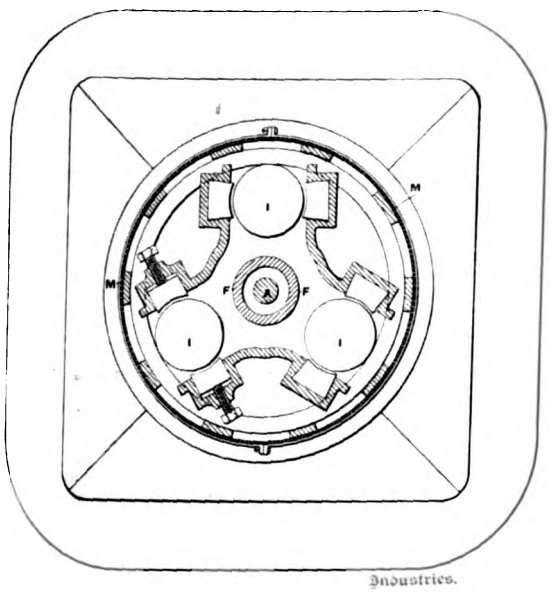
which, when the vehicle has a brake apparatus worked by compressed air, may be charged directly from the main reservoir or train pipe, or in other cases may be charged by a small air compressing pump worked by a motor or by the running wheels while the vehicle is in motion. The air from this reservoir is admitted to the ends D and E of a cylinder C, and the admittance of air controlled by a valve worked by the lever F. The rod of the piston G is linked by a connecting rod to the end of a lever H which is fitted free to turn on one of the running axles A of the vehicle, on which axle at the side of the lever is fixed a square-toothed wheel I. On the face of the lever H are pivoted a gearing lever J and a double-nosed pawl K having noses L and M. One end of the lever J is slotted to receive an eccentric N, and its other end rounded to fit a notch in the cam K. To start the vehicle in the direction of the arrow, the handle O is pushed forward until the piston G is at the end D of the cylinder. The nose L of the pawl K engages with the teeth of the wheel I as shown by the dotted lines. The lever V is next moved to admit air to the end D of the cylinder and give the necessary impetus to the vehicle. As the lever L assumes its vertical position the pawl disengages with the wheel I and the valve of the cylinder is closed by an arrangement of tappets not shown. Claim: Apparatus for starting a vehicle, consisting of a compressed air reservoir, slide valve, cylinder, and piston, in combination with a lever centred on one of the axles of the vehicle, this lever carrying a double-nosed pawl having its attitude determined by an eccentric or crank on the lever so as to engage with teeth of a wheel on the same axle, for driving in the one direction or the other substantially as described.—No. 18909. November 25th, 1889. 6d.



VICES.—*W. Lorey & C. Getz, Philadelphia, & F. S. Dickenshied, Hosensack, Pennsylvania, U.S.A.*—This vice is formed by the combination of a leg vice and parallel vice. The movable jaw is pivoted to the vice slide, and it has a depending leg, which corresponds to another depending leg upon the slide. Pivoted to one of these legs is an eccentric, which bears upon the other leg, and when revolved by a suitable lever opens the two and causes the jaws to close upon each other. In using the vice the movable jaw is screwed out along with the slide and its depending leg to receive the work. It is then closed upon the work by the slide screw and tightened by the eccentric and legs. Claims: (1) A vice having a stationary jaw, a movable jaw, a slide to which the movable jaw is pivoted, depending legs, and an eccentric which is adapted to tighten the jaws as described; (2) a vice having a stationary jaw, a movable jaw pivoted to said slide, a nut secured to stationary jaw, a screw swivelled to the slide and freely passing through the movable jaw and working in said nut, the said slide and movable jaw each having a depending leg and means connected to one of said legs for clamping said jaws, said parts being combined as described; (3) in a vice, jaws having parallel motions in opening and closing in combination with a slide to which the movable jaw is pivoted and an eccentric which is mounted on said jaw in order to close the same against the other jaw as described.—No. 14934. September 21st, 1889. 6*d*.

Digitized by Google

STEAM ENGINES.—*T. Deakin, Manchester.*—The nature of this invention may be understood from the following claim:—In the construction of steam or other fluid pressure motors, making one or more of the parts through which the work of the fluid pressure is transmitted elastic, that is to say, compressible or extensible, so as to present or raise to a greater or less degree surfaces or operating parts which act directly upon the valve spindles or gear, so as to open or close the valves to a greater or less extent, or more or less quickly, in accordance with the position of the said operated parts, or accordingly as more or less pressure is required to meet the load or to regulate the speed of the engine. Six other claims are made referring more particularly to the construction and arrangement of the elastic parts on the prime motors.—No. 2875. February 19th, 1889. 1*s.* 3*d.*



GRINDING MILLS.—*J. S. Chenhall, Bristol, & J. W. Chenhall, Totnes, Devonshire.*—The mill is designed for the purpose of grinding ores and such like material. The illustrations show Fig. 1, a sectional elevation, and Fig. 2, a sectional plan of the machine. A is the driving shaft, driven by a belt pulley B, and its motion steadied by the flywheel W. The lower end of the

FIG. 1.

shaft is supported in the step C, and its top in the socket E of the conical portion of the pan F. The ball carrying frame G is supported upon the shaft and caused to turn with it by a feather, which, however, permits the frame to rise and fall. The frame G is made adjustable upon the shaft by the screw R. The surfaces in contact with the grinding balls I are made of hard metal and are renewable. The operation of the machine is as follows:—The ore or other material is placed in the hopper P, and the vertical shaft with its attachment set in motion by the means provided; the balls will rotate, and as the material from the hopper descends it will be crushed by the balls, but if the supply is too rapid and the bed of the chamber becomes full, the balls rise and

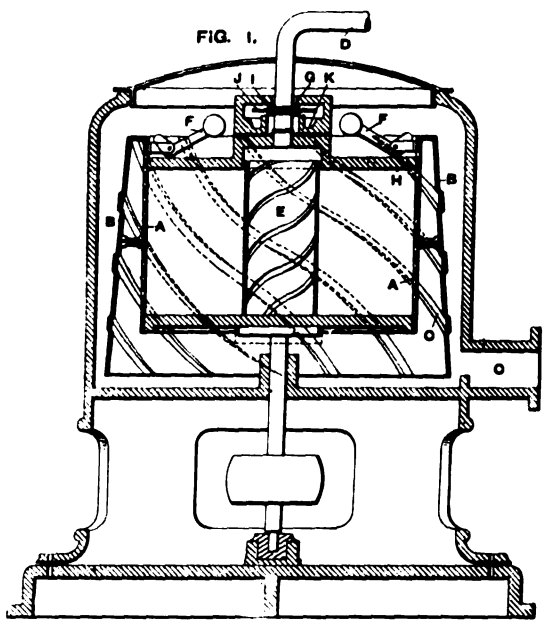
FIG. 2.

lift the frame G which checks the supply by partially closing the opening S, and when only the proper quantity is in the chamber the balls will fall and the frame G will enlarge the aperture and thus automatically regulate the supply. As the operation proceeds the crushed material is discharged by centrifugal force from the perforated screens M. Claims: (1) The automatic arrangement for regulating the supply of material; (2) the adjustable ring S; (3) the insertion of blocks in the pan and the means of adjusting and fixing them; (4) the means for discharging the crushed ore by centrifugal force through apertures in the periphery.—No. 19363. December 2nd, 1889.

REFRIGERATING MACHINES.—*M. C. Bannister, Liverpool.*—Some difficulty has hitherto been experienced in designing a pump or circulating apparatus in such a way that the contents will not freeze solid. To overcome this difficulty large Indian bamboos are used to form the barrel or cylinder of the pump. The joint of the bamboo constitutes the cylinder bottom. The central hole of the bamboo is usually cylindrical, and maintains its shape after long exposure to moisture. The bamboo is also a bad conductor of heat, and it is very tough and strong. Claim: As a new article of manufacture a pump cylinder or barrel formed of the internode of a bamboo, one end of the said barrel being formed either of the adjacent node or of a separate piece of material as described.—No. 4357. March 13th, 1889. 6*d.*

SCREW PROPELLERS.—*E. E. de Facien, Rangoon, India.*—The improvements here described are for the purpose of preventing water escaping laterally from the blade of the propeller, due to the tangential force imparted to it by the propeller's rotation. The propeller blades are provided with a terminal flange at right angles to the terminal plane of the blade. The outer edges of the blades where they bend at an angle to form the flanges are not square or concentric with the shaft, but the leading edge is raised so that in the rotation of the propeller the edge describes the frustum of a cone whose axis coincides with the axis of the shaft. Four claims are made for various forms of the flange formed on the propeller blades for the purpose described.—No. 4888. March 20th, 1889. 8*d.*

BUFFERS.—*S. W. Carlton, Swansea.*—The spring buffers, such as are used for railway purposes, are liable to take a permanent set, so that the buffer heads become loose and are not retained in their forward or outward positions. The object of this invention is to compensate for this slack. For this purpose the bearing of the buffer spring is taken upon a wedge piece. The wedge piece is constructed to slide in behind the spring at right angles to the axis of the buffer. When the buffer spring takes a set it would, in the ordinary form, become loose between its seat and the buffer, but in this case the wedge is forced in behind the loose spring, and so shortens the distance between its seat and the buffer. The wedge is forced in by suitable springs that exert no resistance to the proper action of the buffer, but force in the wedge as the buffer spring becomes set. Claims: (1) In a buffer the combination with the buffer rod and buffer spring or springs, of a supplementary spring or springs, and a wedge automatically controlled by another spring, the arrangement being such as to automatically compensate for slack caused by the permanent set of the buffer spring or springs; (2) the improved buffer, constructed with a supplementary spring and wedge controlled by another spring, as hereinbefore described.—No. 4854. March 20th, 1889. 6*d.*



PUMPS.—*J. C. R. Okes, London.*—The pump parts are constructed in accordance with a previous patent, No. 6249 of 1888, and the present improvement is intended to facilitate its use in mines or wells. The suction and discharge pipes are in line with the barrel of the pump and its stroke. The discharge pipe is formed with a swan neck or bend situated just above the pump. The pump rod by entering this bend passes centrally into the pump barrel, whilst the outside part passes up to the surface of the well, through guides fixed to the side of the rising main. In the case of two or more pumps use is made of two or more swan necks uniting into one rising main, which serves to form the support for the pump rod guides. Claims: (1) A hollow plunger pump or pumps, in combination with the patent No. 6249 of 1888, constructed as described; (2) in pumps the combination of a hollow plunger or plungers, the valves and valve boxes of which are constructed in accordance with the patent No. 6249 of 1888, with a rising main formed with a swan neck as described.—No. 4789. March 19th, 1889. 6*d.*

THRUST BEARINGS.—*J. B. Hardwicke, London.*—The bearing here described is of that class in which friction wheels or rolls are employed. In the present invention the rolls are arranged with their axes radial to the axis of the propeller shaft. They are placed upon each side of a flange or collar which is fixed to the propeller shaft in such a manner that the flange travels upon one set or the other as it is thrust against them by the motion of the propeller. The rolls are supported in a bracket secured to the keelson of the vessel. Two flanges or collars may be formed upon the propeller shaft, and one set of friction rolls used between them. In the case of a double set of rolls whose faces are broad the rolls may be made conical and their smallest ends put towards the shaft. By this arrangement the smallest parts of the rolls travel in contact with the surface of the flange or collar nearest to the shaft, whilst the largest part of the cone rolls move in contact with the outer part of the flange. It also provides means for adjusting the rollers closer to the flange by moving them inwards in the direction of their axes. Claims: (1) The method of using anti-friction rollers revolving in fixed bearings for the purpose of taking the thrust of propeller shafts, in the manner described; (2) the arrangement of one or more sets of pairs of parallel rollers, each set revolving in contact with a collar on the propeller shaft as described; (3) the use of the aforesaid arrangement of rollers alone or in connection with the usual thrust bearing, and the use of the same in connection with an end collar on, or with collars placed between, the ends of the shaft; and (4) and (5) referring to the illustrated parts as shown in the specification.—No. 4788. March 18th, 1889. 8*d.*

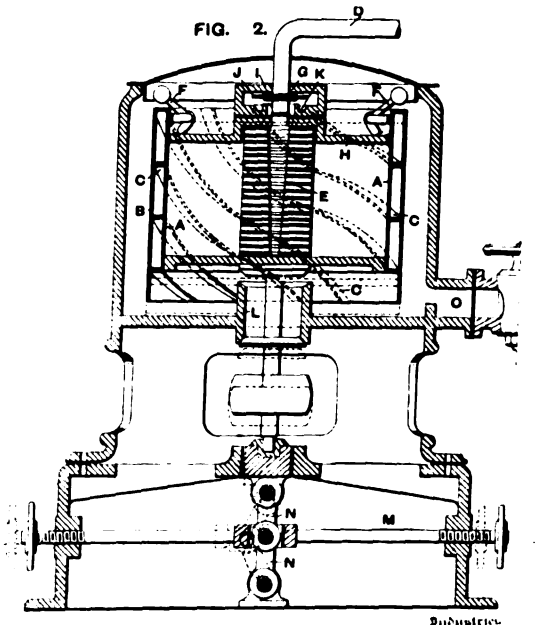
BOILER TUBE STOPPERS.—*W. Dover, Liverpool.*—The appliance is for temporarily plugging an injured or leaky boiler tube. It consists of a mandril having certain parts threaded upon it. A tube is first placed loosely upon it, a little less in length than the tube to be stopped. Upon each end of the bolt and butting against the ends of the tube are next placed hollow or recessed collars, which are fitted to slide upon the bolt. Other collars are now placed upon the ends, and they fit the recessed portion of the first collars and form between the two a small annular space. Between these collars, and in the annular space are inserted rings of lead. When this appliance is introduced into the tube, and nuts placed upon the end of the bolts made to close the parts one against the other, the annular spaces between the collars become diminished, and by reason of the bevelled sides, the lead is forced out radially into contact with the inner surface of the tube. A shield, consisting of a thin piece of metal, may be placed upon the end of the bolt to protect the operator when fixing the appliance against the outrush of liquid or steam. Claims: (1) A tube stopper for marine or other multitubular boilers, in which a ring of lead or other suitable compressible material, of approximately the same diameter as the internal bore of the tube and mounted concentrically on a bevel-edged washer secured on a central operating mandril within one end of the tube, and a like ring or similar material mounted on a similar washer loosely placed on the aforesaid mandril within the opposite end of the tube, are adapted to be simultaneously brought towards one another and to be pressed or squeezed between their respective washers, and bevelled rims of cheeks also mounted concentrically within the tube and kept at a determined distance apart on the mandril aforesaid, whereby they are simultaneously upset or expanded against the inner walls of the tube and form tight plugs or joints at or near each end thereof; (2) in combination with a tube stopper such as described a shield adapted to be mounted on the operating mandril, or on a sleeve placed near the extremity of said mandril, at the front of the boiler, and so formed as to protect the operator, while plugging a fractured tube, against the escape of steam or boiling water; (3) a tube stopper for plugging marine or other multitubular boiler tubes in case of leakage, the whole combined as described.—No. 5005. March 22nd, 1889. 8*d.*

CENTRIFUGAL APPARATUS.—*A. Waldbaur, Stuttgart, Germany.* This apparatus is intended for continuously washing, dyeing, drying, and impregnating fabrics, and the improvements are for the purpose of conducting away the liquors more advantageously. The Figs. 1 and 2 are sectional elevations of two slightly different machines. In them A is the perforated basket for the material to be treated. Attached to the basket is a casing B, with spiral grooves C (Fig. 1), or divisions C (Fig. 2), to more

FIG. 1.

readily deliver the spent liquors to the bottom of the case. The liquors used are delivered through the pipe D to the centre chamber E in the machine. The wall of the chamber E is constructed of perforated plates with grooves as shown in Fig. 1, or of a series of annular plates G, with interstices between them, as shown in Fig. 2. The liquors fall from the pipe D to the bottom of these chambers E, but, by reason of their construction, immediately ascend the walls and pass through in all directions to the material in the outer chamber or basket. After passing through the material, and the perforations in the basket, the liquor is deflected by the casing B, and delivered from the machine by the pipe O. The basket is provided with a lid H automatically closed

FIG. 2.



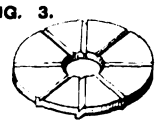


FIG. 3.

by weighted cam levers F, which are thrown from the position shown in Fig. 1 to that in Fig. 2 by the centrifugal force due to the rotation of the basket and its fittings. A tight joint is made for the feed pipe D by attaching to the lid H a round vessel I, constructed with a gutter K, to receive a small quantity of liquid. In the vessel I is a flange J fixed to the pipe D, and therefore held stationary. When at work the vessel I revolves and causes the liquor in the gutter to rise and assume a position round the

Digitized by Google

larger diameter of the vessel and covering the periphery of the flange J, thus making a liquor-sealed joint. As it is desirable for some materials to use the centrifugal apparatus *in vacuo*, or under steam pressure, the bottom of the apparatus, or evacuation channel, is fitted with a packing hoop or ring L, upon or in which the correspondingly turned bottom of the basket runs tightly at its lowest part. The shaft of the basket may be raised or lowered by suitable means, such as making the step adjustable by a screw M and an angle lever N (Fig. 2). In order to enable cops to be exposed to the full effect of steam in this apparatus, rings or portions of rings are inserted into the apparatus, which at the inner side are provided with elastic wire-bundles, against which the cops are placed and held fast. Six claims are made for the improvements described.—No. 2806. February 18th, 1889. 8*d*.

ROTARY ENGINE.—*L. C. Huson, Elmira, New York, U.S.A.*—This is a compound rotary engine constructed of three chambers or cylinders with similar working parts. Live steam is applied to two of the chambers, and the exhaust steam from these passed alternately to the third chamber, which is situated between the other two. Referring to the illustrations, Fig. 1 is a longitudinal

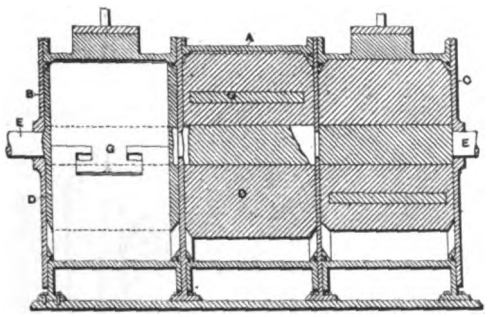

FIG. 1.

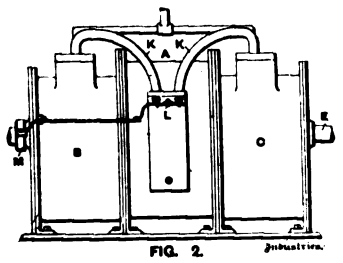

FIG. 2.

section of the engine, Fig. 2 a front elevation, and Figs. 3 and 4 transverse sections. A, B, and C are the three chambers or cylinders through which passes eccentrically the piston rod E. Upon the rod E are fixed the three drums or piston heads D, with sliding plates G. The plates G constitute the piston proper, and are made to assume contact with the sides of the chamber by the introduction of steam between them through the vent holes H as shown in Fig. 4. In each cylinder, I is the inlet pipe for the

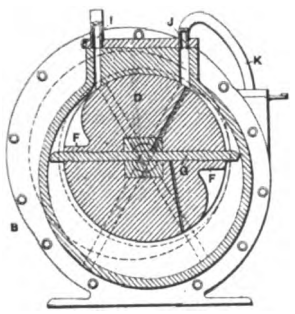

FIG. 3.

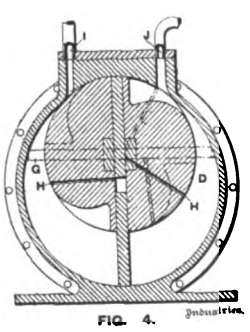

FIG. 4.

steam and J the exhaust. The steam as it is admitted by I strikes against the face F and the part of the piston G that projects, causing the piston rod to revolve. As the piston revolves more of it becomes exposed to the action of the steam until it reaches its maximum effective position, Fig. 4, and the exhaust of the other side commences. The exhaust from the cylinders B and C is conducted by the pipes K and the valves L to the third cylinder A. The valves L are operated by an eccentric M upon the piston rod E. Ten claims are made for the rotary engine described—No. 3469. February 26th, 1889. 8*d*.

REMOVING SNOW FROM STREETS.—*O. A. Warren, Liverpool.*—The method adopted is to apply to the snow, by distributing machinery, a liquid mixture of salt and water artificially heated. The apparatus is mounted upon wheels, and consists of a steam generator, a vessel for holding salt, a second vessel for receiving snow, and a tank for holding the liquid resulting from melted snow and the addition of salt. The salt vessel is situated at the top of the apparatus, the snow beneath it, and the tank below that. The snow is melted by passing steam from the generator into the snow vessel. As the snow melts the resulting liquid falls into the water tank below, where it is mixed with salt and heated to a higher temperature by coils passing from the steam generator through the tank. The liquid thus heated is forced out by steam through nozzles arranged along the bottom of the apparatus. The mixture of salt with the liquid in the tank is conducted either by hand or mechanical means, such as a revolving feed screw. Five claims are made.—No. 2987. February 20th, 1889. 8*d*.

MACHINE FOR WRINGING CLOTHES.—*S. Crow, Huddersfield.*—The principal features of this machine are the appliance used instead of springs for pressing the rollers together and the device for fastening the machine to the edge of a tub. The clothes are passed between two rollers made preferably of vulcanised india-rubber, whose elasticity compensates for the action of springs, and allows various thicknesses to pass between the rollers. The machine is constructed of two side plates secured together by a shaft, which forms the bearing for levers supporting the roller spindles. These levers are situated close to the side plates at each end of the shaft. Between the legs of each set of the levers are placed small cams attached to the guide board of the machine in such a manner that, by lowering the guide-board into the position for working the machine, the rollers are closed together by the action of the cam. For fastening the appliance to the edge of a tub the side plates are formed each with a depending leg, and one of the levers upon each side of the machine has a similar leg. The tub is nipped between these legs by the action of the cams produced by lowering the guide board as described above. Four claims are made for the machine as described.—No. 20579. December 21st, 1889. 6*d*.

PERCUSSION TURBINES.—*C. L. Hett, Brigg, Lincolnshire.*—Improvements are here made in the method of supplying the water to the turbine. Hitherto the water has been supplied by a simple nozzle or nozzles, and the flow regulated by a cock or valve. This method has been found to be defective, inasmuch as when a portion of the water was shut off the velocity of the jet was diminished and a loss of efficiency resulted. In this invention use is made of an adjustable nozzle of a similar character to the steam jet valve of an injector, by which the quantity of water striking the buckets of the percussion turbine may be regulated without loss of efficiency. The flow is regulated in this case by shifting the conical valve within the conical-shaped nozzle to or from the discharging aperture and so varying its area. Claim: The combination of a controlling nozzle fitted with a cone valve as described with a percussion turbine or impulse wheel.—No. 20708. December 24th, 1889. 6*d*.

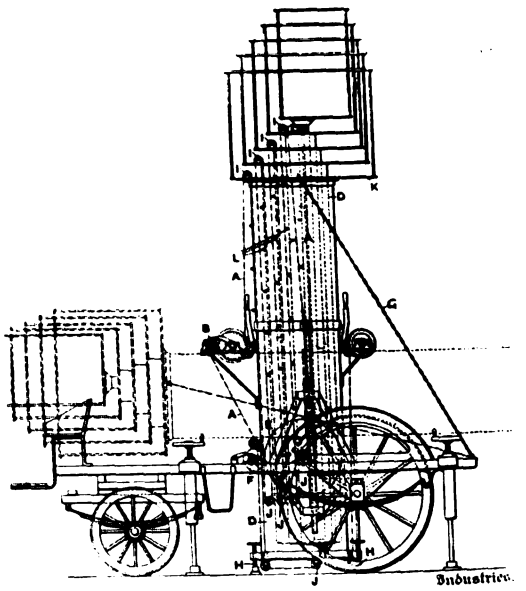
MILLING CUTTERS.—*T. Eynon, Cleveland, U.S.A.*—Instead of making the milling cutters with the teeth and head of one piece of steel, and having the teeth to extend the whole width of the head, the inventor constructs the two separately and the cutting parts of small pieces of round steel rod. The object of this is to produce a milling tool in which the power is gradually applied and to prevent the tool heating. The head of the tool is bored with a small round hole radially to its axis for the insertion of the short steel rods. The rods are held in place by set screws and the protruding ends cut or milled away to form the cutting edges. All the teeth or cutters are of the same length, and project the same distance from the periphery or face of the head, so that all points of the cutting edges are equi-distant from the centre of rotation of the head. The cutters are preferably arranged in parallel lines around the face of the head, so that they alternate, the teeth of one series slightly overlapping the line of the teeth of the other, so that when in operation there will be no fin or unfinished portion left upon the surface of the material being milled. The milling tool head may be made of a number of similar plates screwed or bolted together, and the short lengths of steel nipped between them. Nine claims are made.—No. 20726. December 24th, 1889. 8*d*.

TURNING CYLINDRICAL STAVES.—*C. Werner & R. Pötzsch, Meerane, Germany.*—The operation of turning the staves is performed by passing the rods in their rough state through a hollow conical cutter-head revolving upon its axis; the staves are passed through in the direction of the conical cutter-head's axis. A head-stock supports the hollow mandril upon which the cutter-head is mounted, and a guide for the staves as they are passed through the cutter-head. An adjustable holder for the staves is fitted upon the bed of the machine in a line with the axis of the cutter-head. The cutter-head supports three or more flat, shear-like knives, lengthways of the cone. These knives are fitted upon slides which are worked by screws geared to a common large gear wheel or annulus concentric to the cone and fitted at its base free to revolve. By the revolution of the annulus, or one of the screws, the whole of the screws revolved and the cutters are shifted simultaneously either in a direction from the apex to the base of the conical cutter-head or the reverse, so opening or closing the cutters from or to each other. Five claims are made.—No. 5008. March 22nd, 1889. 8*d*.

CENTRIFUGAL SEPARATING MACHINES.—*W. L. Wise, London. (S. Jonsson, Schoenbergsgade, Denmark.*)—This invention relates to an improved method of supplying milk to centrifugal separating machines. The milk is caused to enter the separator exactly at that point at which is situated a milk stratum of specific gravity similar to that of the entering milk. The reason for so supplying the milk is not to disturb the strata of milk which have already formed, so that the centrifugal process goes on undisturbed. If the milk is entered close to the wall of the separator, it tends to go towards the centre until it reaches that stratum of milk whose specific gravity is equal to its own. If, on the other hand, the milk is entered where the specific gravity is less than itself, it is carried out towards the periphery of the machine and so again disturbs the process. To effect the delivery according to the invention, a supply pipe leads down into the vessel behind a ring of an S-shaped section fixed near the bottom. The liquid flows in behind the ring, and enters and mixes with the other milk by passing under the edge of the ring. Two claims are made for supplying the milk to a part of the separator containing milk of equal specific gravity, and for the appliance to effect such delivery as described.—No. 4653. March 16th, 1889. 8*d*.

ELECTRICITY.

TELEPHONE MOUTH PIECES.—*R. Cotterell, Crossmyloof, Renfrew.*—The object of this invention is to increase the volume of sound and render more certain the action of vocal sounds in telephone transmitters. For this purpose a conical-shaped mouth-piece having open ends is fitted at its small end to the transmitter. The small end of the mouth-piece enters and is fixed to a metal band which is constructed to be clipped or fastened to the transmitter. A band of india-rubber surrounds the small end of the mouth-piece and intercepts the metal clip and the surface of the transmitter case. Claims: (1) A conical-shaped mouth-piece having no delicate internal fittings; (2) fixing conical-shaped mouth-pieces within a holder or clip; (3) fixing to the base of telephone mouth-pieces rubber pads.—No. 3022. February 20th, 1889. 6d.



MAGNETO-ELECTRIC MACHINES.—*G. Bowron, London.*—The improvements here specified relate principally to the permanent magnet, but also to the commutator and brushes. In place of the ordinary horseshoe permanent magnet a straight one is used, and it conducts the magnetism through the armature by means of two suitably shaped pole pieces attached to the ends of the magnet. A Siemens shuttle-wound armature is used. This armature, as is well-known, delivers a varying current of electricity, which attains a maximum value twice during each revolution of the armature. The commutator and brushes are modified in such a manner that, when desired, the armature may be short-circuited either just before, or just after, the time when the armature is giving the maximum current. To accomplish this there are attached to the commutator two projecting arms which strike as they revolve a contact brush, and so short-circuit the armature. Claim: The improvements in magneto-electric machines as described.—No. 4998. March 22nd, 1889. 8*d*.

CHEMISTRY.

COATING METAL SHEETS WITH TIN, &c.—*R. Heathfield, Darlaston.*—The appliance is constructed to dispense with the ordinary rolls which are wholly immersed in the metallic bath and to substitute for them a pair of rolls placed upon the side of the pot. A pair of rolls is thus fixed to the inlet side of the bath and a pair at the outlet side; those at the outlet side being partly immersed in the metallic bath. The sheets are fed in by the inlet rolls and pass between curved guides in the bath to the partially immersed rolls upon the exit side of the pot. By this arrangement the wear and tear of the machinery is reduced. Claims: (1) In apparatus for coating metal, the rolls on the exit side of the pot, whether hung in an inner or outer frame and whether protected or not from the superfluous flux, in combination with the feed rolls upon the inlet side of the pot as described; (2) in apparatus for coating metal, removable main guides in combination with the other parts of claim 1 as and for the purpose described.—No. 7311. May 2nd, 1889. 8*d*.

MISCELLANEOUS.

FIRE ESCAPE.—*L. Smither & P. Duhamel, Paris.*—The escape is composed of a series of tubes which close one within the other when not in use, but when brought into action are drawn out by means of chains. The illustration shows a side elevation of this appliance closed, but moved into a vertical position ready for elevating. Its normal position is shown by the dotted lines. To move the tubes D to the upright position shown, racks C are pivoted to the outside tube and geared to the wheels E and F, which are revolved by a hand crank attached to the spindle shank of the wheel F. The racks C work in conjunction with the guy chains G, so that as the racks C are raised the chains G pull the tubes into an upright position, the tubes having a tendency to tilt towards the front. The weight of the tubes can be removed from the frame of the carriage by the foot screws H. The different lengths of tubing are forced out the one from within the other by the chains A attached to the windlass B, which is worked by a hand crank. The chains A pass over pulleys I and

under pulleys J upon the top and bottom of each tube as shown by the dotted lines. The tubes are of rectangular form, excepting the centre one, and guided one within the other by V pulleys running in their four corners. Upon the top of each tube are platforms K provided with rails, and down the side of each are bars L to form a ladder. The appliance is fitted with a second windlass for the purpose of raising and lowering a basket to or from the top of the tubes. Claims: (1) The construction of tubular ladder above described, fitted with trunnions, and capable of rocking in vertically adjustable bearings on a travelling carriage; (2) the means above described for raising the tubular ladder to a vertical position, sustaining it when extended, and lowering it to a horizontal position; (3) fitting the tubes which compose the telescopic ladder with platforms for the use of the attendants and for carrying the appliances; (4) the construction of divided axle; (5) the means above described for fixing the position of the apparatus and relieving the carriage from the weight of its load while the telescopic ladder is in use.—No. 1679. January 30th, 1889. 8*d*.

Copies of the British specifications may be obtained on application to H. READER LACK, Esq., *Comptroller-General, Patent Office, Southampton Buildings, London, W.C. The published price must be remitted, together with a sum sufficient to cover postage, which may be reckoned at ½d. for every 10d. or fraction of 10d. Remittances exceeding one shilling must be made by Post Office Order.*

BAND-SAWING MACHINES FOR HEAVY TIMBER.

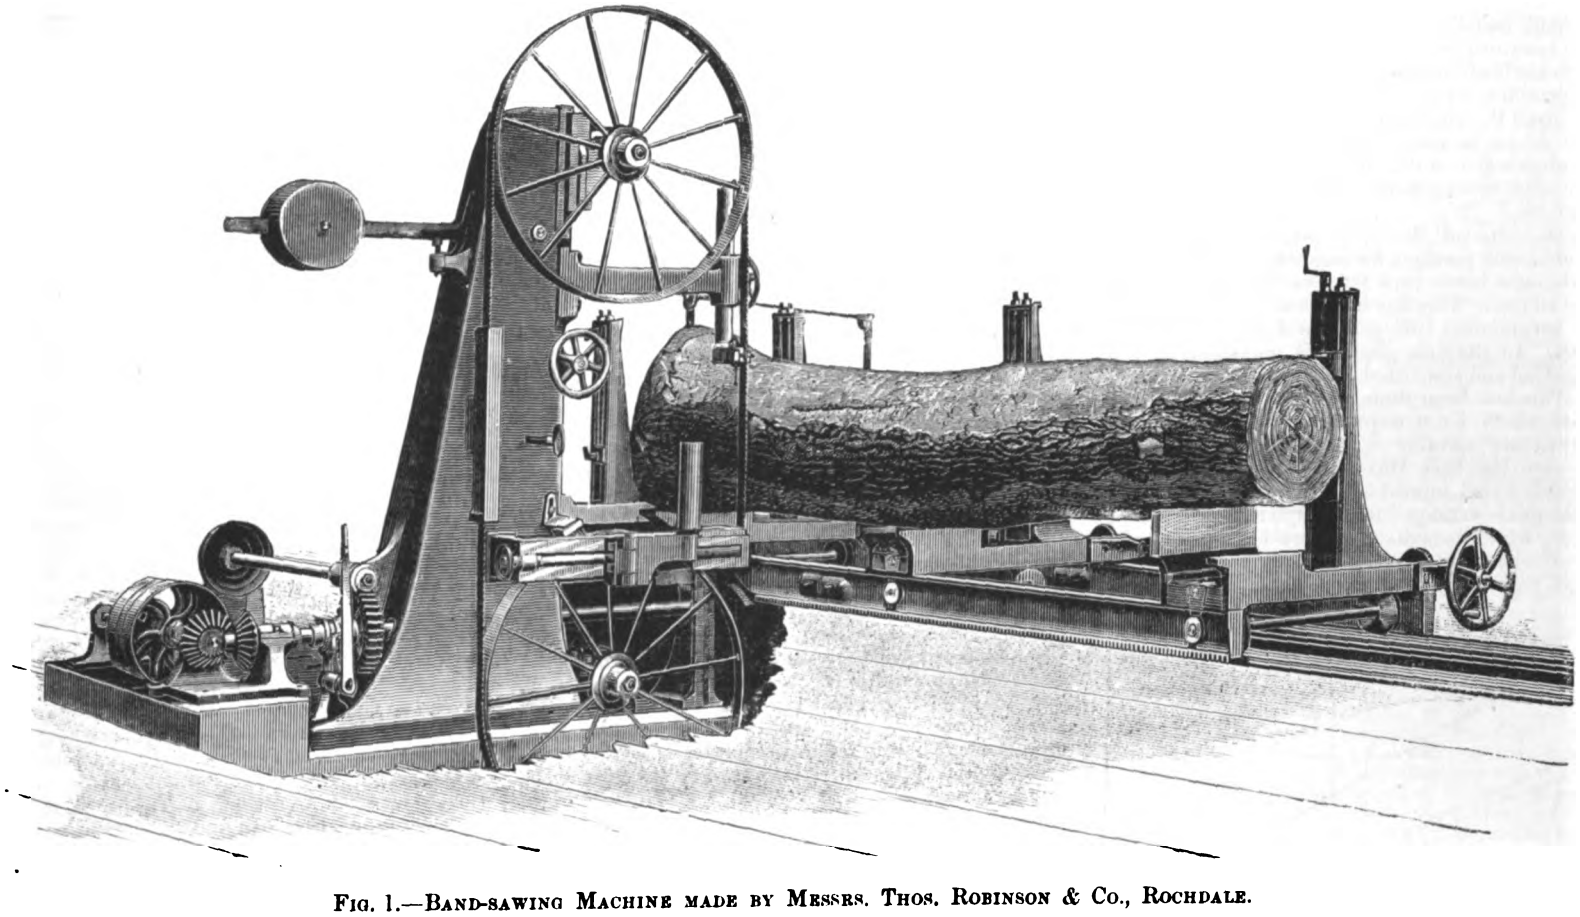

Fig. 1.—Band-sawing Machine made by Messrs. Thos. Robinson & Co., Rochdale.

BAND-SAWING MACHINES FOR HEAVY TIMBER.

By M. Powis Bale.

During recent years the introduction of band-sawing machines for converting heavy timber has made very considerable progress, more particularly in America, where a great number of machines of the largest size are in operation. When we consider that a well-constructed band-sawing machine will convert logs of the heaviest class with considerable rapidity, and at the same time effect a great saving in power and wood, it is somewhat remarkable that their development for log sawing has not been more rapid. This may be to a certain degree attributed to the difficulty there used to be in obtaining band-saw blades of the necessary width and temper to withstand the very considerable strain to which they are subjected, and to the want of provision of adequate means of keeping the saw in a true vertical line. These difficulties have now been entirely overcome and the machine made commercially successful. The object of the present article is to consider briefly some of the points to be desired in the construction and working of a machine of this class.

Main Frame.—In designing the main frame or column of the machine, strength with rigidity in working must be secured. In the best practice a hollow-cored or box casting made in one piece and arranged with an extended base is usually employed, although some American manufacturers prefer a wrought iron girder column bolted on to a heavy base plate. Whichever is used it is important that the base plate and foundations generally are sufficiently massive to absorb the vibration of the machine when working at its full speed. The base of the machine is fixed below the mill floor, and the foundation bolts pass entirely through the masonry. As regards the foundations dressed stone is best, as it offers a better resistance than brickwork. It should be accurately levelled, laid on a bed of concrete, and set as nearly perpendicular to the direction of the stress as possible. The quality of the work turned out and the longevity of high-speeded machines depend more on the stability of the foundations than is generally imagined, and any reasonable outlay in this connection is usually money well invested. With the object of securing increased steadiness in operation we have seen machines working with success in which the upper saw spindle runs in bearings fixed on the top of the column and the lower spindle in a vertical line beneath the base of the machine. An additional pair of bearings placed outside the driving pulleys of the bottom spindle to withstand the pull of the belt are an advantage.

Band Saw Wheels.—Perhaps the most important features in the construction of a band-sawing machine are the saw wheels. These should combine in the highest possible degree strength with lightness; this is more particularly the case with the upper saw wheel, as should it be too heavy it may over-run the bottom or driving wheel, and be a fruitful cause of the breakage of saws. It may be as well to explain the reason of this. The top saw wheel is driven by the tension of the saw blade upon it. When the top saw wheel is running at its full speed it acts somewhat after the fashion of a fly wheel; consequently, when the speed of the saw blade is suddenly checked by its entry into the wood as it commences to saw, the acquired momentum of the top wheel, not being checked in a like proportion, over-runs the saw and the driving wheel, and creeps, so to speak, up the back of the saw, which consequently buckles or fractures at the point of resistance—viz., where the saw enters the wood.

The wheels should be made of wrought iron or steel, covered with wood at the periphery, and this again covered with a band of vulcanised india-rubber or leather. The wheels should be turned all over, the top wheel mounted elastically, and both be *perfectly* in balance. Should they be the least out of balance the consequent centrifugal force causes a constant jumping motion on the wheels, which will ultimately break the finest saw blades. For log sawing the saw wheels must of necessity be of large diameter—in fact, within moderation, the larger the better—as, should the arc of contact of the saw with the wheel be too acute, the blades are rapidly cracked and fractured. The diameter of the wheels should be in proportion to the thickness of the log sawn, varying from 6ft. to 12ft. diameter, by about 8in. on the face. It is difficult to formulate a rule on the subject, but a wheel of, say, three times the diameter of the thickness of the wood to be sawn will generally be found to be suitable. The top saw wheel must be arranged to cant, so as to direct the saw blade to any desired point on the face of the wheel, and so equalise its wear; care must be taken, however, that the teeth are not allowed to run so far in as to tear the covering. The outside india-rubber covering should be a flat ring about 1in. thick, sprung on and carefully cemented in its place. If leather is used, two thicknesses, one of sole and one of buff leather, can be recommended; these will require riveting in their places.

The saw wheel spindles should be of steel supported by two pairs of bearings to each spindle; these can be mounted in an adjustable slide for the top wheel and in standards or pedestals for the bottom wheel. The author has found this arrangement much preferable for heavy machines to the plan of mounting the wheels to run on studs or using single bearings or bushes. The top wheel spindle and slide must be capable of being adjusted vertically to suit saws of various lengths; this can be secured by means of a hand wheel and screw working into a gun-metal nut fitted in the slide casting. To keep the saw to its proper tension, and therefore lessen the breakage of the blades, a weighted counterbalanced lever or spring combination arranged to act on the top saw wheel slide must in all cases be fitted. For covering the wheels with wood—which should be hard and well seasoned—ash or walnut, about 2in. thick, is suitable; it should be accurately sawn in segments, lap-jointed, and glued together, fastened to the wheel with counter-sunk coach screws, and turned up in its place. Strong steel or wrought iron tubes make excellent spokes for the wheels, combining, as they do, strength with lightness. With the object of preventing the upper saw wheel over-running the lower, some engineers make the latter about one-third heavier than the former, so that the increased momentum may prevent its speed being materially reduced when an increase of work is put upon it. For machines where the duty is very severe, the spokes of the wheels may be "staggered" with advantage; in this case the centres should be made heavier, and the rim of the wheel strengthened with wrought iron plates or pads where the spokes are attached. The top wheel can be set to an angle with the lower wheel by means of a set screw, cam, or worm gearing, whichever the arrangement of the wheel or slide may render most convenient. Wheels without flanges are to be preferred, as the flanges do little to support the back of the saw blade, and have a tendency to twist and buckle it, and heat and crystallise the steel. Some American makers construct the lower saw wheel of greater diameter than the top, but the writer fails to see the advantage of having the arc of contact of the saw different on the two wheels. By thus lightening the top wheel, the tendency to over-run the bottom wheel would of course be reduced. With the same object in view—viz., to equalise the speed of both wheels—centrifugal governor gear has also been fitted to the top wheel, but the writer is unable to speak from experience as to its success or otherwise.

Tension Apparatus.—To secure effective working, and prevent as far as possible the fracture of the saw blade arising from a rigid tension, the slide or bracket carrying the top saw wheel is always mounted elastically. This is effected through the medium of a strong spiral or coach spring, or by means of a counterbalanced compound lever, the amount of tension in the latter case being regulated by moving the weight nearer to or

Digitized by Google

further from the fulcrum. No absolute rules can be made as to the amount of tension necessary on the blade, as this depends largely on the size and nature of the wood, the gauge, width, and condition of saw and rate of feed of the wood. If the rate of feed is fast the tension of the saw must be increased to enable it to face the wood without buckling. Great tension is bad, and often leads to fractures, especially if there should be any small cracks in the blade, a condition often found in saws of hard or crystalline steel. More tension on the saw should not be given than is required to keep it to the line. The slide should be so evenly elastic that, should the saw meet an obstruction and give a jump, the spring or lever compensating arrangement would give with it, and so save a fracture.

Saw Guides.—One of the chief troubles found in the early band-sawing machine for logs was the difficulty of keeping the saw blade in a true vertical line when sawing heavy timber. This has now, however, been in a large degree surmounted through means which we will briefly discuss. In the first place it is important that the saw be guided and supported as it enters and leaves the wood. This has been done in a variety of ways. The best with which I am acquainted is to fit in the table an adjustable metallic friction revolving guide wheel to receive the back thrust of the saw, and an adjustable guide fitted immediately beneath the table, with a similar guide arranged in an adjustable counter-balanced slide, fixed immediately above the surface of the wood. If the work is very difficult two pairs of movable steel rollers placed immediately above the cut

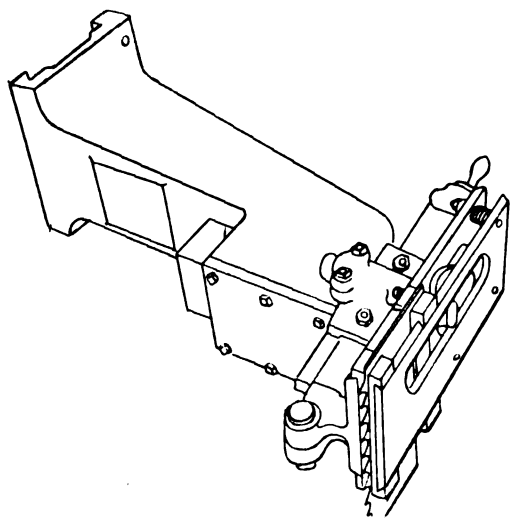

Fig. 2.—American Guide and Arm.

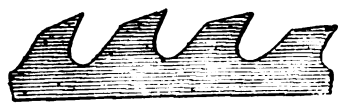

Fig. 3.—Saw Teeth for Ordinary Timber.

and below the table can be used. With these revolving rollers the friction is very small, and the saw is supported considerably. The ordinary flat adjustable guides are usually of wood. Apple or pear wood soaked in oil is suitable, but some makers use plates of steel. In sawing resinous woods, where it is necessary to keep the blade clean by lubricating it, the writer has used with advantage an oil-box guide. This is made in gun-metal, and consists chiefly of two flat oil-boxes, placed one on each side of the saw. The sides of the boxes nearest the saw blade are made adjustable, and drilled with a number of small holes, through which the oil can percolate. Hard brushes can also be fixed to sweep the blade clean at the back of the machine with advantage. The packing pieces, whether of wood or metal, should be adjusted so as to just touch the blade on either side and so prevent its undue vibration in working. Another plan to keep the saw to the line is to deflect the blade as it enters and leaves the cut by means of side friction rollers placed on a spindle vertically and made to bear against it. The revolving steel roller receiving the back thrust of the blade must be capable of adjustment, as the duty is very severe, and the blade must not be allowed to cut too deeply into it, or it will have a tendency to heat and twist the blade. The roller need not be more than $\frac{1}{2}$in. thick; it should be about 4in. diameter, made of hardened steel, fitted on a steel spindle carefully mounted in phosphor-bronze bearings. These, together with the lower side guides, can be mounted with advantage on a bracket arranged to swivel so that the guide may be readily adjusted to the plane of the saw blade.

We illustrate above (Fig. 2) an improved form of guide and guide-arm, of American origin, in which the pivot is in line with the teeth of the saw, but slightly to one side, and it is stated that the amount of movement which this position entails upon the cutting edge of the saw is so slight as to be immaterial. The hardened steel roller is fitted between steel plates; the outside plate is $\frac{3}{8}$in. thick, with a slot cut in it to make room for the nut on the roller. This outside plate is bolted to the guide casting by three stud bolts, which pass through adjusting screw plugs, thus enabling the distance between the plates to be adjusted at will. The upper and lower edges of the plates are bevelled as shown, and the side guides, which are gibs of brass or steel, are slipped on and screwed fast. The whole guide is then pivoted close to the cutting edge of the saw, and by loosening one nut the guide may be adjusted by the handle shown at the back whilst the saw is in motion.

We have seen another very good guide, consisting of a hard steel disc, arranged to rotate on its axis, so as to present fresh wearing surfaces to the back of the saw. The side guides are two half-discs, which are made to embrace the sides of the saw, and can be readily adjusted by a screw when the saw is in motion.

Timber Carriage.—This is usually a table of wrought iron running on friction rollers or rails, and operated by rack and pinion and friction gearing. It should be fitted with adjustable sliding heads and dogs for holding the timber firmly in position, and be speeded to travel from, say, 3ft. to 30ft. per minute, according to the size and nature of the wood to be sawn. By means of a hand lever and suitable friction gear the traverse of the table may be readily started, stopped, or reversed as may be required. By the employment of a friction disc the rate of feed may be regulated to a nicety. Rope feeds and feeds similar to those used in rack saw benches are also used, but care must be taken that the speed of the feed is not excessive, or the saw blade may be buckled and broken, as, being of much thinner gauge and usually running at a slower speed than a circular saw, it will not stand so much "crowding." The levers and hand wheels controlling the stopping, starting, feeding, and adjusting of the logs should be placed so as to be readily under the control of the operator, and as near together as may be. In the most advanced machines the head blocks can be simultaneously moved by a lever, and the thickness of the cut regulated to the greatest exactness by means of an indexed gauge plate.

Band Saw Blades.—It need hardly be said that, no matter how well a machine be designed and made, unless the cutting tool is of the finest quality the result is always unsatisfactory. What is required in a band saw is toughness, combined with a certain degree of hardness. If the blade be too soft it will not stand to its work, and will require constant sharpening. If it be too hard it will crystallise and break; it must, however, be sufficiently hard to keep well its cutting edge. French band saws have long been held in the best repute, but some English firms are now making very good ones. It is not easy to distinguish by inspection the quality or temper of a saw blade, and a user must necessarily rely to a great extent on the repute of the saw maker. Not a bad test is to "hammer set" a few of the teeth coarsely, and if the temper is too hard, a tooth will probably crack. The gauge of the saw should be in proportion to the diameter of the saw wheels and the nature of the work. A thin gauge saw will stand better than a thick one, therefore a saw of a greater gauge than is required to stand up to the work should not be selected; but for cutting hard close-grained woods, such as oak, beech, &c., a thicker saw will be required than for medium and soft woods. Long blades will stand better than short ones. To do thoroughly satisfactory work a band saw should have teeth correct in shape, and the blade be uniform in gauge, width, toothing, sharpening, setting, and temper. The question as to the shape of the teeth is a matter not easy to deal with, as it should be regulated by the nature of the wood they have to cut. Teeth with square or angular gullets should be avoided, as they are much more liable to crack at the roots of the teeth than those with rounded gullets. For converting ordinary timber a saw with teeth similar to Fig. 3 is suitable. For sawing oak, ash, elm, and hard woods generally* more teeth should be used than for soft wood, and these filed further back. For woods of woolly fibre, such as poplar, saws with deep teeth and coarse space and set should be employed, to allow an easy clearance for the sawdust, and overcome its clinging properties. Coarse teeth and set should also be used for cutting pitch pine. For soft woods, ordinary hand saw teeth are often used. It is important that all the saw teeth be sharpened and set alike. With this object in view automatic sharpening and setting machines have been introduced with satisfactory results. A suitable gauge for saws 8in. wide for cutting soft and medium woods is 17 S.W.G. with a pitch of about $1\frac{1}{4}$in. The amount of set should vary according to the density of the wood, the harder the wood the less the amount of set necessary and the greater the number of teeth. For converting very hard woods, such as iron wood, the author prefers fine-toothed and set mill saws to either circular or band saws. For sawing deals, band saw machines carrying two blades have been introduced into this country with success, a cutting speed of about 6ft. per minute being maintained, with a kerf loss of about $\frac{1}{16}$in. for each cut. It is very important, in order to secure an even motion on the saw blade, that the brazing be very completely done, and that the joint be of exactly the same thickness as the rest of the blade.

Speed of Saw Blade.—The question of the speed of the blade is a factor of considerable importance in securing efficient working. A short saw running over medium-sized wheels cannot, with safety, be run so fast as a long saw running over large ones, by several thousand feet per minute. A speed of from 5,000ft. to 10,000ft. per minute—according to the nature of the work and construction of the machine—may be considered a fair margin.

Notes on Working.—Keep the saw to a moderate tension and see that the wheel coverings are not allowed to get rough or worn. In heavy machines it is important that the machine be set in motion gradually, as it takes a little time to overcome the inertia of the top saw wheel, and if the power be suddenly applied there is a risk of snapping the blade, especially if worn or defective. Saw blades should in all cases be slackened out after finishing work, to allow of their contracting freely, as in working the blade is found to expand considerably, the slack being taken up by the workman, and if it is left with too rigid a tension, and cannot contract readily, it cracks, and flaws are set up. When sawing resinous woods, keep the blade as clean as possible by lubricating and brushing it. After taking a cut the log should be set back very slightly, so as to clear the teeth of the saw, as the table runs back, preparatory to taking another cut. The saw should never be crowded with too quick a feed, or it will twist and buckle, and not cut true and regular.

Circular and Band Saws Compared.—Circular saws for breaking down heavy timber, when compared with band saws used for the same purpose, possess the advantage of greater output, and are perhaps a little more easily managed. On the other hand, the band saw uses much less power and wastes much less wood. The first cost of a good rack-feed saw bench and a band saw for logs is slightly in favour of the former. In America, where circular saws are used of much thicker gauge than they are here, the saving in power and wood through using a band saw is correspondingly greater. In sawing pine the average output on a first-rate circular saw in America may be set down at about 40,000ft. per day of ten hours, whilst a band saw in the same time would produce about 30,000ft. I believe these figures have been exceeded, but I think they may be taken as a fair average. An American authority, in comparing circular and band saws, says that "the kerf of circular saws average $\frac{5}{16}$in., and in sawing 1,000ft. of inch boards 312ft. is turned into sawdust. The average kerf of the band saw is about $\frac{1}{12}$in., and in sawing the same amount of boards it turns 83ft. into sawdust. This shows a clear saving of 229ft. in favour of the band saw on every 1,000ft., and on 1,000,000ft. of 229,000ft.," an enormous saving, to say the least. The figures here given must, however, be very considerably discounted when applied to this country, as the circular saws in use here are of very much thinner gauge; but supposing a reduction of 50 per cent., and the saving is still very great. This is, of course, particularly the case when valuable woods are converted. Again, if the band-sawing machine is carefully made and handled, the work produced is superior to that of the circular saw. This may be chiefly accounted for through the greater freedom from vibration of the band saw when cutting. As the advantages arising from the employment of band saws become better known and appreciated, there is little doubt that they will, on their merits, rapidly supersede large circular saws for converting heavy logs.

We illustrate in Fig. 1 (page 217) a band-sawing machine for breaking down heavy logs, made from the designs of Messrs. Thomas Robinson & Sons, Limited, of Rochdale. The main frame is a hollow-cored casting, mounted on a substantial bed-plate, to secure, as far as may be, freedom from vibration when working. The saw wheels are of wrought iron, mounted on steel spindles, running in double bearings. The top saw wheel is adjustable vertically, and can be made to cant, so as to alter the pathway of the saw. A weighted compensating tension lever, to take up the slack of the saw and prevent its breakage, is fitted. The travelling table is arranged with a rack feed, and fitted with improved adjustable head blocks, for regulating the thickness of the cut. The rate of feed can be readily adjusted to the nature of the wood, and all the motions of the machine are immediately under the control of the operator.

NOTES ON PATENTS.

IV.

THE COMMERCIAL EFFECT OF THREATS.

MANUFACTURERS frequently find that their market is destroyed by threats that their goods are infringements of Letters Patent. They have, of course, no cause of complaint where there is an actual infringement of valid Letters Patent. It is found, however, that threats of infringement are very common where no *legal* rights are infringed. Genuine patentees will, in cases of infringement, test their rights with a substantial manufacturer instead of destroying the market. Unscrupulous patentees make use of their so-called privileges by threatening the customers of their competitors. Many customers are fully aware that, by using or selling an infringing article, they are as liable as the manufacturer for the consequences of infringement. The customer feels, in nine cases out of ten, that it is not worth his while to inquire into the matter further; and thus the manufacturer loses the market for his goods, and possibly the threatening patentee secures the order.

Previous to the Patent Act of 1883 a patentee was within his rights in threatening persons with actions for infringement, provided he did so without malice. It was said in his favour that he was acting *bonâ fide*, and was merely cautioning the public of the existence of his patent rights. A complete change was introduced by the Patent Act of 1883. If a person claiming to be a patentee threatens any person with legal proceedings, he is now called upon to substantiate two things: 1, That his patent is valid; 2, That the goods complained of are infringements. This is the practical effect of Section 32 of the Patents Act of 1883. Any person aggrieved by the threats can commence an action to restrain a continuance of the threats, and for the damages sustained in consequence of them. There have been since the commencement of the Act several cases of this class. In most of them an injunction, with the costs, has been awarded to the plaintiff, but not damages of any substantial amount. There is no doubt that this Section has had a very beneficial effect. Patentees are now very cautious as to their threats.

It might be mentioned that, in the cases before referred to, the Courts have been most liberal in their construction of what is a "threat." Advertisements, notices to the trade, letters to individual customers, and even a lawyer's letter have been held to be "threats" within the meaning of the Section. There is no doubt that much damage was caused by unscrupulous patentees before the passing of the Act of 1883. This damage has been checked, but not done away with. Although a manufacturer is injured by threats, and has now the means of redress, it does not follow that it is worth his while to put the law in motion. The law is slow and expensive, and the patentee is frequently not a man of substance. This sometimes causes the manufacturer to find an antidote to the threats. This antidote occasionally effects what is desired, and enables the manufacturer and his customer to carry through their business.

It consists of an indemnity to the customer guaranteeing him against any legal proceedings. It is, of course, only worth while doing this where the contract is a large one. In an ordinary purchase there is no implied guarantee by the manufacturer that the article sold is not an infringement. The principle *caveat emptor* applies, and a few purchasers have found, to their cost, that they have paid for a machine which they have been prevented from using.

Patents are not always taken out for the purpose of protecting an invention, but sometimes for subsidiary objects. We had occasion, in a recent issue, to call attention to the fact that great numbers of patents were obtained for the purpose of marking goods with the word "patent." All privileges are liable to abuse; but means should be taken (for the benefit of genuine inventors) to revive the sanctity of Letters Patent. In certain foreign countries the penalty for the acts above mentioned is more severe than here, the defendant being liable to imprisonment and fine.

ON THE MECHANICAL APPLIANCES EMPLOYED IN THE MANUFACTURE AND STORAGE OF OXYGEN.*

Extraction of Oxygen from Atmosphere.—About thirty years ago the eminent French chemist Boussingault made the discovery that at a temperature of about 1,000° Fahr. the monoxide of the metal barium would absorb oxygen readily from the atmosphere, with the resulting formation of the dioxide; and that at a higher temperature of about 1,700° Fahr. the oxygen thus absorbed would be given off again, and the monoxide would apparently be restored to its original condition. Following up this discovery, Boussingault advocated the use of barium oxide for the economical preparation of oxygen on a large scale. He found however that the barium oxide gradually lost its power of recovery; and although many attempts were made by himself and others to overcome this difficulty, no one until within the last few years appears to have succeeded, and from a commercial point of view his discovery remained of little value. To the brothers Brin is due the credit of having surmounted this difficulty, and thereby paved the way for a method which within the last two years has been developed by the Brin's Oxygen Company into a reliable commercial process.

Barium Oxide.—As this is the basis on which the Brin process is founded, a brief account will be given of the way in which it is prepared and used, before going into the mechanical details of the process. Barium oxide is a mineral substance closely resembling lime in its properties. It is found combined in nature as "heavy spar" (sulphate) and "witherite" (carbonate), both of which occur most frequently in lead districts. One of the most important salts formed from the raw material is nitrate of barium BaN_2O_6, which when in the crystalline form is found the most suitable for conversion into the barium monoxide BaO employed in the Brin process.

This oxide, which is known commercially as "baryta," is formed by decomposing the nitrate in the following manner. A series of fire-clay crucibles, each of about eight pints or one gallon capacity, are heated in a suitable open coke fire to about 1,600° Fahr. Without being removed they are gradually charged with barium nitrate, which becomes rapidly liquefied by the heat, and boils for about three hours. During this process of boiling, gases are driven off in the form of nitric oxide N_2O_2 and oxygen. When the boiling ceases, a porous mass of hard barium monoxide, equal to about half the original weight of nitrate, is left in the crucible; and this is allowed to bake for another hour, under the same conditions as to heat, in order to drive off as far as possible all remaining traces of nitrogen oxides. The crucibles are then taken out of the fire, and placed in a closed chamber, where they are allowed to cool down slowly. The baryta is afterwards removed, and stored in air-tight drums until required for use.

Baryta thus manufactured lasts a long time, and costs about 75s. per cwt. It is not claimed for this method of preparing the oxide that it is a cheap one. When the Brin's Oxygen Works in Horseferry Road, Westminster, were erected three and a half years ago, this particular form of baryta was not commercially known; and as, owing to its permanent nature, the quantity required for the Brin process was so limited, it was thought advisable to manufacture the oxide on the premises in the manner just described. An oxide of barium, however, is largely prepared in a somewhat similar manner for use in the production of the powerful bleaching agent "peroxide of hydrogen" H_2O_2; and the manufacturers of this material have already taken the matter up, with the result that lump baryta in a porous state can now be procured for about 50s. a cwt. As yet, however, this material is hardly supplied in the physical condition required for the production of oxygen, for it fails to combine in the requisite degree the qualities of porosity and hardness. In appearance a lump of baryta might be mistaken for pumice stone, but in action it is very different. When put into water it slakes with greater rapidity than lime, and gives off much greater heat.

Production of Oxygen.—While the careful preparation of the baryta is very important, its treatment when in actual use for the production of oxygen is even more important. It was found by Messrs. Brin that, when the air was properly purified before being brought in contact with baryta thus prepared, it had little injurious effect; and also that, by peroxidising the baryta under a slight pressure, and deoxidising it under a partial vacuum, they were able to reduce the range of temperatures, and thus to avoid the high deoxidising temperature previously employed, which had acted destructively on the baryta. By the careful observance of these conditions the difficulty encountered by Boussingault and others has been practically overcome: in proof of which it may be mentioned that some of the baryta placed in the original oxygen-producer erected in Horseferry-road is still at work.

The Brin method of working was as follows:—By means of a suitable pump, air was *drawn* through a purifier containing caustic lime and soda, which extracted the moisture and carbonic acid. The purified air was then delivered under a pressure of about 10lb. per square inch into a series of steel retorts, charged with lumps of baryta about the size of a walnut. These retorts were placed horizontally in a brick chamber, and heated to a temperature of about 1,100° Fahr. In passing through the baryta the oxygen was extracted from the air, and the nitrogen was allowed to escape again into the atmosphere through a relief valve. After the baryta had taken up all the oxygen it could—which, theoretically, is about 1·25 cubic foot at atmospheric pressure per lb. of baryta, though this quantity is never reached in practice—the air pump was stopped, and the heat of the retorts was increased to about 1,600° Fahr. The pump was then restarted with its action reversed, so as to draw from the retorts. At a vacuum of 26in. of mercury, or nearly 13lb. per square inch, the baryta yielded up the oxygen it had absorbed during the previous operation, and this oxygen was drawn off through the pump and delivered into a n ordinary gas holder. When all the oxygen had in this manner been drawn off, the pump was again stopped, the heat lowered, and the first operation repeated.

On the starting of the works in Horseferry Road, an oxygen-producing plant was erected there on these lines; but it was soon found that the process would have to be much simplified before oxygen could be obtained cheap enough for industrial applications. The injurious effect of constant expansion and contraction on the steel retorts and on the brickwork of the furnace will be readily understood, as well as the waste of time and fuel, and the constant supervision required: all of which were the necessary results of working at two temperatures. Fresh experimental work was accordingly undertaken with a view to overcoming these difficulties, and has resulted in greatly simplifying and cheapening the entire process. These results have been brought about mainly by the adoption of one temperature for both operations, by the use of vertical instead of horizontal retorts, and by the automatic working of the entire process.

The figures on pages 220 and 221 illustrate a plant working on these lines, capable of producing 10,000 cubic feet of oxygen per day of twenty-four hours; and with the exception of the general arrangement being here slightly altered for the sake of clearness, it is in all respects similar to oxygen-producing plant recently erected.

Oxygen Producer.—The oxygen producer, shown in Figs. 1, 2 and 3, consists essentially of a self-contained carbonic oxide generator O, having a combustion chamber P on the top, which communicates on either side with chambers C containing the vertical retorts. The carbonic oxide generator is similar to that employed by Mr. W. A. Valon in the Ramsgate and other gas works; and it is well adapted for use in connection with an oxygen producer, where it is a matter of great importance to be able to maintain a uniform heat of from 1,350° to 1,450° Fahr. on the retorts containing the baryta, and where it is essential to have a producer requiring little attention. The generator is charged with coke every six hours through the firing door Q on the ground level, and is clinkered out every twelve hours through the door R. A feature of these generators is that they contain no fixed fire-bars; a slight steam-jet is used, mainly to prevent the formation of clinker on the walls. Air for primary combustion of the fuel is admitted through small portholes on each side of the clinker door R; and secondary air, for burning the carbonic oxide into carbonic acid in the combustion chamber P, is first heated by being drawn through passages in the walls on each side of the generator, up the back wall, as indicated by the arrows, and into the combustion chamber immediately above the opening in the crown through which the carbonic oxide is admitted. Combustion then immediately takes place, with consequent expansion. The hot gases leave the combustion chamber through the fire-clay sleeves G, which are so arranged as to prevent the gases from impinging directly upon the retorts. These sleeves are also fitted with fire-clay nostril pieces, which can be changed or adjusted at will through the openings in the side walls at H, thus giving a complete control over the heating of the retort chambers. The gases are drawn off from the bottom of each chamber, as indicated by the arrows, through fire-clay sleeves, into flues communicating with a common chimney in the back of the producer. The draught in each retort chamber is controlled by an independent damper; and the gases can either be conducted away direct, or be drawn down into any existing flue.

Retorts.—The retorts are of steel, twenty-four in number, twelve in each bay, in which they are placed vertically. They are 9ft. long in their exposed surface, 7in. external diameter, and ¼in. thick. Experiments are now being made with cast-iron retorts, with a view to the adoption of this material instead of steel. The retorts contain altogether about 2,100lb of baryta in lumps, as already described. The weight of the retorts is taken by a cast-iron box-plate at the top, through which they pass, and which is shielded from the action of the heat by special fire-lumps, as shown in Fig. 1. A cast-iron plate shielded in a similar way is used at the bottom of the retort chambers; but here a gland joint is formed by means of a ring of asbestos, to allow for free expansion of the retorts. The flanges and covers of the retorts are of cast iron; and the joint between them, which is found a particularly satisfactory one, is made as shown in section in Fig. 4, by beading the retorts at each end, recessing the covers to receive them, and placing a ring of thin sheet copper between the faces. The cover is then screwed down, thereby moulding the copper ring to the retort end and the cover, and so forming an absolutely clean air-tight joint. The copper ring can be used over and over again.

Connecting Pipes.—The bent connecting pipes between the retorts at the bottom, and between the retorts and the branch cast-iron pipes at the top, are of weldless steel, and are connected in every case by means of a conoid-conical joint. To prevent the possibility of these connecting pipes at the bottom of the retorts getting choked by small baryta lumps or dust, a cast-iron shield-plate is attached to the inside of the cover. As shown in Fig. 1, all the joints in connection with the bottom of the retorts are accessible through the clinkering pit of the carbonic-oxide generator. The arrangement of piping on the top of the producer and the details at V will be described later on.

Air Pump.—In small installations, such as that now described, the same pump is used for the twofold operation of pumping into and out of the retorts. It has therefore to be designed with a view to obtaining the high vacuum necessary for deoxidation. The pump shown at L in Figs. 1 and 2 is the type which up to the present has generally been adopted. It is manufactured by Messrs. Frank Pearn & Co., of Manchester, and is capable of creating under ordinary atmospheric conditions a vacuum of 29in. of mercury or 14lb. per square inch. It is a vertical combined double-acting steam engine and pump, with two air cylinders on top, each cylinder capable of passing one cubic foot of air per revolution. For cooling these cylinders they are surrounded by tanks containing circulating water.

Purifiers.—The purifying plant, shown at M in Figs. 1 and 2, consists of two wrought-iron or steel chambers of 96 cubic feet capacity, and two cast-iron chambers of 19 cubic feet capacity. The larger chambers are charged with quick lime CaO, and are filled only half full, in order to allow for expansion when the lime is hydrating; and the smaller ones are fully charged with caustic soda NaOH in the lump state. The purifiers are so connected by means of iron piping and valves, that the air to be purified passes through one or both of the lime chambers, and through only one of the soda. They are charged through a man-hole on the top, and emptied through a cleaning door at the bottom. The air passes through the purifiers on its way from the pump to the retorts, and is consequently under the same pressure in the purifiers as in the retorts. It is admitted to the purifiers at the bottom, and passes off at the top. It is first passed through one or consecutively through both of the lime purifiers, where the bulk of its carbonic acid and moisture is absorbed; and then through one soda purifier, where the remaining traces of impurity are trapped; the work done in the soda purifier is consequently very small.

The quantity of carbonic acid in the atmosphere is very slight, only about 0·04 per cent. in volume; and it varies but little under different atmospheric conditions. The quantity of moisture in the atmosphere is very changeable, and in this country may be said to vary in volume from 0·3 to 3·3 per cent.; and under average atmospheric conditions air contains in volume about 1·25 per cent. of moisture. The lime in the purifiers consequently hydrates with far greater rapidity than it carbonates. As a rough rule it may be said that one ton of quick lime will purify three million cubic feet of air. In the plant now described 86,000 cubic feet of air pass through the purifiers per day, and each purifier when charged contains about one ton of quick lime. If therefore the full efficiency were taken out of the lime, and the work done by the soda were disregarded, one lime purifier would have to be re-charged every five

weeks. As complete slaking of the lime however means the formation of a mass offering a good deal of resistance to the passage of air, in actual practice the first of the two lime purifiers is thrown out of work as soon as ever it begins to occasion a perceptible back pressure, which with the purifiers now described would be after about four weeks' working. Whilst this purifier is being re-charged, the other lime purifier and the soda purifier do the work; and when the freshly charged purifier is re-started, the order of working the lime purifiers is reversed, so that the one last charged shall always be the second in action.

The life of the caustic soda depends on the efficiency of the lime purification. One of the two soda purifiers is always active; and as the soda has only to act the part of a catch to what has escaped the lime, it does not require to be often changed. Caustic soda has a very strong affinity for moisture and carbonic acid. As it hydrates, it liquefies; and this liquid has to be periodically drawn off through a tap at the bottom of the soda purifier. The amount of liquid thus drawn off is a good indication, not only of the efficiency of the lime purification, but also of the amount of caustic soda hydrated, the liquid soda being about double the weight of the caustic. When about half of the caustic soda has been drawn off in this way, the purifier has to be thrown out of work and filled up again, whilst the other soda purifier is brought into action.

Cost of Purification.—Assuming that after they had done work in the purifiers the slaked lime and the liquid soda were valueless, the cost of purification per 1,000 cubic feet of oxygen would be about threepence. But these materials, though spent so far as complete purification of the air is concerned, are by no means valueless. The slaked lime may be used for building purposes, for which it is found as good as lime slaked in the ordinary way; and in gasworks, where it is confidently hoped that the use of oxygen will be extensively adopted, this slaked lime has only to be taken to the ordinary lime purifiers, and there used for abstracting carbonic acid and sulphur from the coal gas in the usual way. The liquid soda, although the quantity used is very small, is disposed of for about one-half the original cost of the caustic material. From these facts it will therefore be seen that the purification of the air forms a very small item in the cost of oxygen manufacture.

The plan of purifying the air after it has passed through the pump, instead of before, has only recently been adopted. The advantages it offers over the old methed are:—Firstly, that as all the suction passages between the pump and the atmosphere are clear, the full quantity of air is drawn in and delivered by the pump; and secondly that traces of pump lubricants, which previously, in spite of all efforts to prevent their doing so, found their way into the baryta, are now effectually arrested by the purifiers.

Automatic Reversing Gear.—This gear is shown at K in Figs. 1 and 2. It consists of four cocks, A W Y Z, attached to a table, and geared with pistons, as shown in Figs. 8 and 9, by means of which they are actuated. Steam pressure is admitted to the cylinders in which the pistons work, by means of retention valves actuated at any desired moment by adjustable cams; and the motion to rotate the cam shaft is transmitted from the air pump by means of pawl and ratchet gearing. The cocks A and W and Y are reversed by means of the cylinder E. A is a three-way cock attached to the suction pipe of the air pump. N is a similar cock attached to the delivery pipe of the air pump. V is a two-way cock working in conjunction with A and W. Z is a three-way cock similar to A and W, and worked separately by the cylinder F.

The details shown at V on the top of the furnace work in connection with the automatic reversing gear, and are shown in Fig. 7. They consist of a double-acting automatic valve U, and a double hand distributing valve-box T. The automatic valves U are attached to the same vertical spindle, in such positions that when one is off its seating the other is on. They are actuated by a corrugated steel diaphragm, which is subject to vacuum or pressure according to the position of the cocks A, W, and Y. The diaphragm is about 12in. diameter and No. 26 W. G. or 0·018in. thick, and is corrugated cold between dies. The total fluctuation it is subject to is less than half an inch at the centre; and as proof of its efficiency it may be mentioned that the first of these automatic valves was started seven months ago, and has been steadily at work with the same diaphragm ever since. From tests actually made, the pressure obtained on the valve by the diaphragm under a vacuum of 28in. of mercury or about 14lb. per square inch is 700lb., the valve itself being 2½in. diameter. This valve is con-

Digitized by Google

nected at one end to the pipe I, as shown in Figs. 1 and 2, and at the other end to the distributing valve box T. The latter is so arranged that, by screwing the hand wheels out or in, the direction of the air passing into the retorts may be periodically reversed, thus very much lessening the tendency the baryta has to settle when the currents of air are always in the same direction.

Cycle of Operation.—In order to convey some idea of the efficiency and cost of producing oxygen with the foregoing appliances, which constitute an existing plant for the purpose, the complete operation will now be described, assuming the air pump to be running at the rate of 60 revolutions per minute, and the automatic gear to be set so as to give four complete operations per hour, and assuming also that deoxidation has taken place and the automatic gear has just reversed all the cocks.

Air is drawn in from the atmosphere through the cock A into the pump at the rate of 120 cubic feet per minute. It is there compressed to about 10lb. per square inch, and delivered through the cock W and pipe D to the purifiers. Having passed through these, it returns by the pipe Y^1 to the automatic gear, passes through the two-way cock Y into the pipe I, and thence into the automatic valve U, where its pressure on the diaphragm causes the latter to close the bottom valve and open the top. The air being thus unable to get away through this valve passes into the distributing box T, where it is caused to enter the pipe N, in which it is subdivided, and passes consecutively through two retorts, where the oxygen is absorbed by the baryta. On leaving the retorts the nitrogen passes into the pipe J, and through another passage in the distributing box T into the upper chamber of the automatic valve U; and the top valve being open, it escapes thence through the release valve S into the atmosphere. It is by means of this release valve that the pressure in the retorts is controlled. When the peroxidation of the baryta has continued for 7½ minutes, or any other desired period, the requisite cam of the cylinder E comes round, and lifts a retention valve, which admits steam to the cylinder and thus reverses the cocks A, W, and Y. By this action the purifiers are cut off *under pressure*, and are thrown out of communication with the rest of the piping. The suction cock A is thrown into communication with the retorts, and the delivery cock W with the cock Z. Suction being thus created between the retorts and the pump, a vacuum is formed, which, acting on the diaphragm of the automatic valves U, reverses the position of these valves, closing the top and opening the bottom, thereby cutting off all communication with the atmosphere, and opening a communication with the top and bottom of the retorts, which enables the vacuum to be more rapidly created. As pure oxygen is not obtained until a vacuum of 26in. of mercury has been created in the retorts, it is necessary to blow away the gas drawn off before this vacuum is reached. The gas is therefore delivered through the cock Z into the atmosphere, until the proper quality of oxygen is obtained. The cock Z then reverses, and directs the oxygen into the holder, the reversal being caused automatically by suitable adjustment of the cams. When this deoxidation of the baryta has continued for the desired time, the automatic gear again reverses the cocks, and the whole process is repeated indefinitely.

A governor is used in order to control the speed of the air-pump when working under the different conditions of peroxidation and deoxidation; and a safety-valve is fixed on the delivery pipe between the pump and the automatic gear, so as to prevent any excessive pressure from being thrown on the pump whilst the operations are being reversed. It will thus be seen that the reversing of the operations is entirely automatic.

Labour.—Beyond firing the boiler and the carbonic oxide generator of the producer, and lubricating the pump and gear, nothing is left in the hands of the workman. Special labour is of course sometimes necessary: as, for instance, when a purifier has to be changed, or the baryta has to be taken out of the retorts to be broken up again, which latter, owing to a certain amount of cohesion, it is found advisable to do every three or four months. But working under ordinary conditions, with small installations such as the one described, where oxygen would be used in connection with some other process, and where steam could be taken from some existing boiler, no additional labour would be required.

Purity.—There is, however, another improvement of equal importance which has been effected by the automatic reversing gear, and that is in the quality of oxygen delivered to the holder. So long as the shifting cock Z was controlled by hand, the quality of oxygen could never be relied on, as any carelessness on the part of the workman might mean the admission of a quantity of air to the holder. With the automatic gear, however, such a contingency is impossible; and the quality of oxygen in the holder depends entirely on the length of time allowed between the reversing of the cocks A, W, Y, and the cock Z. The highest quality attainable in practice is from 97 to 98 per cent.

Cost of Production.—The cost of oxygen must always vary with the conditions under which it is made. The quantity of ordinary gas coke used in the carbonic oxide generator is from 12 cwt. to 15 cwt. per day; and as a rough rule, for installations ranging from 4,000 to 10,000 cubic feet per day, the pump power required is 1 i.h.p. per thousand cubic feet of oxygen, lessening, of course, as the plant increases in size. The actual cost of production, allowing for depreciation of retorts and baryta, probably ranges from 2s. per thousand cubic feet in coal gas works to 7s. in works specially erected for the production of oxygen only, where additional charges have to be made for labour and rent.

Although, in a process which has already shown itself capable of so much improvement, further improvements may yet be realised in the shape of a more perfect extraction of the oxygen from the atmosphere, there can be little doubt that the essential difficulties have now been overcome, and that a cheap and simple mechanical process for the manufacture of oxygen is at the command of engineers and chemists, who will not be long in finding applications for it.

In retail business with the supply of cheap oxygen the demand has been daily increasing. For while during 1887 Brin's Oxygen Company sold from their works in Horseferry Road no more than 142,000 cubic feet of oxygen for limelight and other purposes, the quantity they sold during 1889 amounted to just 1,000,000 cubic feet, notwithstanding that the Manchester Oxygen Company have within the last few months taken over the trade of the whole of the North of England.

High-Pressure Storage Cylinders.—All this gas has been compressed and delivered in high-pressure cylinders (Fig. 5), which are charged to 120 atmospheres, and vary in capacity at that pressure from 3 to 225 cubic feet, ranging from 3in. to 5½in. outside diameter. They are spherical at one end, and have a neck formed on the other, into which a high-pressure valve, shown in section in Fig. 6, is screwed and sweated. The material used in their construction is mild steel, and they are either solid-drawn or lap-welded. Up to 40 cubic feet capacity the cylinders used by Brin's Oxygen Company are solid-drawn and seamless; the larger sizes are lap-welded.

The seamless vessels are made by Messrs. Taunton, Delmard, Lane, & Co., of Birmingham, who, the author understands, now make them up to 9in. diameter and 5ft. long. They are made by taking a thick circular flat slab of steel, which by repeated heating and pressing in a hydraulic machine is moulded into a tube with a spherically closed end. The final processes of drawing are carried out with the steel in a cold condition, and annealing intervenes between each cold process. When the requisite size is obtained, the open end of the tube is nozzled or swaged in so as to form the neck. This repeated process of drawing acts beneficially on the strength and rigidity of the metal. The thickness of seamless vessels is rather less than that of lap-welded cylinders of the same diameter, and varies from ⅛in. for vessels of 3in. diameter to $\frac{5}{16}$in. for those of 9in. diameter. The ordinary hydraulic test applied is 2 tons per square inch. The trade in these cylinders has sprung into existence very rapidly, and Brin's Oxygen Company now have many thousands of them passing through their hands.

Compressors.—The compressors employed for filling the cylinders are of a three-stage type. They were originally designed by Mr. Howard Lane, of Messrs. Taunton, Delmard, Lane, & Co., and have since undergone many improvements and alterations. In those now employed, the first cylinder is double-acting, being 5½in. diameter with a stroke of 9in. The second and third cylinders are single-acting, having a stroke of 9in., and are 2⅜in. and 1⅜in. diameter respectively, being fitted with ordinary hydraulic rams instead of pistons. Gas enters the first cylinder direct from the holder, and is compressed in three stages until it leaves the third cylinder, from which it enters the vessel to be filled. The gland joints are formed with ordinary hydraulic leathers, together with a small quantity of water, which is admitted with the gas, and acts also as the cylinder lubricant. The water after it leaves the compressor is separated from the gas by gravity, and periodically drawn from a receiver. The three compressing cylinders, in order to be kept cool, are surrounded by a tank of cold water, which is always circulating.

The compressor is coupled to the crank-shaft of a 10 h.p. vertical engine, by which it is driven, the engine being fixed on the same foundation as the compressor. At a speed of 90 revolutions per minute this compressor will deliver 1,000 cubic feet of gas per hour at a pressure of 120 atmospheres.

Conclusion.—The compressor completes the mechanical appliances in connection with an oxygen factory. If the author has succeeded in showing that the Brin process is a simple mechanical method of manufacturing oxygen, the object of this paper will have been attained. For information respecting the industrial applications already established of this gas, reference may be made to a paper read by Mr. W. A. Valon before the Gas Institute at their annual meeting last year (Transactions, 1889, page 41), and also to a paper read by the company's chemist, Dr. Thorne, before the Society of Chemical Industry about a year ago (Journal, 1889, page 82).

FOREIGN INDUSTRIES.

(From our own Correspondents.)

(FOR LATEST TELEGRAPHIC DESPATCHES SEE PAGE 225.)

PARIS, 4TH MARCH, 1890.

COAL.—The reports from all the centres of the coal mining industry describe the demand for industrial coal as exceptionally strong. This demand is not wholly due to an increased consumption of fuel. Consumers, fearing an interruption of the output by strikes, are imitating their German neighbours, and are stocking largely. Purchases are made for prompt delivery. The supply falls short, however, of the requirements, and prices are in consequence steadily rising. With the rise in prices the demands of the miners increase and their opportunity for exacting an advance in the rate of wages improves; so that the action of consumers, undertaken in self-defence, tends powerfully to bring about the dreaded event. One consequence of the high prices prevailing is a notable extension of the trade of the importers of English and Belgian coal. The former especially is now seen in localities where it had never before penetrated.

A BELGIAN CHAMBER OF COMMERCE FOR PARIS.—It has been decided to establish in the French capital a Belgian Chamber of Commerce, which, it is said, will have the sanction and support of the Belgian Government.

IRON.—Iron holds its position in the market, thanks, not so much to a brisk demand on the part of consumers, as to the high and still rising prices of coal. Here in Paris business is slack, and the tone of affairs weak; but in the provinces the situation continues fairly good. Manufacturers, generally, have plenty of work in hand, and though fresh orders do not come in so rapidly as they did a few weeks back, they are sufficiently abundant to ensure a good trade for the first half of the current year. Beyond this the prospect is less encouraging, for there are no large orders in sight, and it is not easy to see where a very brisk business is to come from. Pig iron in the Longwy district is less firm in price.

THE FOREIGN BREAD QUESTION.—An agitation is being set on foot to induce the Government to impose an import duty on bread. According to a statement prepared by the bakers' syndicate in the North, their industry is being ruined. At Roubaix, for example, there were 250 master bakers in 1887; now the number does not exceed 190. At Halluin there were in that year 25, while now only 4 remain. About $\frac{2}{3}$ of the bread imported comes from Belgium. The rapid growth of this trade is strikingly shown by the customs returns. In 1877 the imports for the year amounted to 63,442 cwt. Ten years later it had increased to 93,524 cwt.; in 1888 it rose to 253,814 cwt., and last year the amount reached 561,050 cwt.

NAVAL CONSTRUCTION IN 1891.—The French Minister of Marine has just made arrangements for the shipbuilding which is to take place in 1891, the total amount of credits to be asked for in the Budget of the department being about £2,320,000. The ships upon which this sum is to be spent, as well in Government as in private dockyards, comprise ten ironclads, one first and two second class ironclad cruisers, two first and four second class cruisers, two torpedo cruisers, five torpedo boats, two ironclad gunboats, one despatch boat, twelve open sea torpedo boats, and thirty-five first-class torpedo boats, or sixty-eight in all. Of the ten ironclads four—the "Neptune," the "Brennus," the "Tréhouart," and the "Magenta"—are in course of construction, and of the six new ones to be laid down one is to be named the "Carnot." The first-class ironclad cruiser, the "Dupuy-de-Lôme," is to be pushed forward at the Brest Arsenal, while the first-class cruisers, the "Alger" and the "Isly," are to be finished at the same arsenal.

ELECTRIC LIGHT AT PARIS.—At a meeting of the Municipal Council at Paris a short time ago M. Paul Brousse, the Prefect of Police, proposed that the Avenue de Clichy should be lighted by electricity. He stated that the number of crimes committed in that quarter was on the increase, and that as long as darkness prevailed the deeds of darkness would continue.

BERLIN, 3RD MARCH, 1890.

COAL TENDERS.—Only nine tenders were received this year for the supply of 17,170 tons of steam coal for the Berlin works, against 18 last year. Of these four were from mine-owners in Westphalia. Silesian coal was offered only through middlemen. The firm of Cäsar Wollheim, which deals with something like one-third of the production of Upper Silesia, tendered from 18s. 10d. to 20s. 6d. per ton, against 15s. 9d. to 16s. 10d. last year. The Westphalian coal was offered, for screened and washed nuts, at 26s. to 27s. 2d., against 16s. 9d. to 19s. last year. Berlin merchants tendered at 16s. 10d. to 19s. 5d. for unscreened and 20s. 2d. for round and nuts.

PIG IRON.—The high level of prices for German pig iron affords an opportunity to the importers of foreign iron, which they are turning to good account. English iron is being offered for sale both in the Eastern and the Western provinces, at prices which are several shillings below those asked for German produce of a like quality. As a consequence the tone of the market is weaker. The production of pig iron in Germany, including Luxemburg, in the month of January amounted to 374,066 tons, against 391,523 tons in December and 367,111 tons in January of last year. Production is still restricted in some localities by a short supply of coke.

LABOUR PROSPECTS.—The effervescence among the working men of all classes is increasing, and the prospects of German industry are thereby rendered, if not actually gloomy, at least much less bright. The probability of another general strike of coal miners is a cause of great anxiety. But the evil is by no means confined to the coal mining industry. A feeling of discontent is manifesting itself among the metal workers, and numerous partial strikes are now in progress in various parts of the country. Every industry is, indeed, more or less troubled by strikes.

THE JUTE TRADE.—The association of Austro-Hungarian jute manufacturers has appointed a committee to inquire and report concerning the present situation of the jute trade, and especially to consider the desirability of establishing an export syndicate. By reason of the greater rise in the prices of raw jute and the increased cost of production due to dearer coal and higher rates of wages, the margin for profits on woven goods has diminished to nearly the vanishing point. Efforts are being made to form a convention to regulate the home markets. The imports of raw jute last year amounted to 1,286,342 cwt. against 1,178,790 cwt. in 1888.

ASSOCIATION OF DISTILLERS.—The Association of Distillers, which has been holding its general meeting, now numbers 2,168 members. The annual report shows that, while the commercial situation leaves much to be desired, the technical development of the distilling industry is making constant progress. In the laboratory of the association 299 analyses were made for members. The school of distillery, with its sectional departments for the manufacture of starch and pressed yeast, was attended in 1889 by 16 distillery owners and 58 managers. The financial state of the association is satisfactory.

ELECTRIC LIGHTING.—After several adjourned discussions, the municipal authorities of Breslau have definitely decided to adopt the system of lighting by electricity. The contract for the installation has been given to the firm of Siemens and Halske, who will proceed at once to prepare the central station at the Carmelite Barracks. Power will be provided at first for the maintenance of 8,000 glow-lamps. To meet the cost the authorities have opened a credit of one million marks (£50,000).

STEAM HEATING ON THE PRUSSIAN STATE RAILWAYS.—On most of the main lines of the Prussian State Railway system the railway carriages are now heated by steam, and the success is so great that the carriages on the branch lines are to be fitted with similar heating arrangements. The steam is supplied from the engine, and travels along pipes which are arranged underneath the carriages. In the first and second class compartments the temperature may be regulated by the passengers, but in the third class compartments the travellers are baked or frozen according to the will of the guard or other official.

THE LEIPSIC CYCLE EXHIBITION.—The exhibition of cycles at Leipsic, which was opened on the 22nd ult., is not so great a success as was expected, and the novelties shown are not very striking. The space is only half occupied, and many of the leading European manufacturers are not represented at all. Mr. Larsen, of Liége, exhibits a cycle with pneumatic tyres, but it is very bulky and ugly.

TELEPHONES IN GERMANY.—The traffic on the telephone line between Berlin and Breslau is so great that the postal authorities are considering the advisability of erecting an additional wire between these two centres. The subscribers in the outlying towns of Upper Silesia complain that they can never get a word in with Berlin, as the telephone is continually occupied by Breslau subscribers. The second wire will therefore be very welcome in Upper Silesia.

MANUFACTURE OF OZONE.—A company has been started in Berlin, under the name of the Ozone Manufacturing Company of New York and Berlin, to work the patents of Dr. Graf & Co., of Berlin. The particulars of the process are not at present known, but if the process is feasible and simple the company will have an immense future before it.

VIENNA, 3RD MARCH, 1890.

THE COAL MARKET.—The brisk demand for Bohemian coals has been followed by such an increase of the price that people are becoming almost terrified. In Prague a committee has been constituted to petition the Government for taking measures against the steady increase of the prices. The capital value of the collieries is rising. The North Hungarian Coal Company has contracted for the construction of a railroad to connect their works with the State railways; by means of this line the Hungarian market will receive the production of three large collieries of the Grau district

THE IRON MARKET.—It is difficult to report about the situation of the iron market. Its position is so firm that it seems never to change. The events in the English market are followed closely by sellers here. Last week a distrust was felt, but now this influence has entirely disappeared. A little motion is visible in Bohemian foundry products, which increased a little. This fact shows that the consumption keeps at its height. The situation of the market is not only supported by home consumption but also by a good demand from abroad. Some Westphalian works are negotiating with the Alpine Montan Company for the delivery of a large quantity of ore and iron, and it will depend entirely on the railway tariffs if the contract will be closed or not. The Erste Brünner Maschinenfabriks-Gesellschaft held a meeting last week for the purpose of increasing its stock. The sale of this company last year was concluded at 1,200,000fl., but their capacity has not been great enough to make much profit. The resolutions of some railway companies to enlarge their lines and rolling stocks, new contracts for constructions, and the activity of the shipbuilding establishments show that there is an excellent prospect for the coming season.

BRUSSELS, 4TH MARCH, 1890.

THE COAL MARKET. The situation of the coal market remains very good. Prices meet with some opposition on the part of some buyers, but their resistance is of very little avail. Coke maintains its price of 35fr., and coking coal of good quality is nearer 23fr. than 22fr. A deputation of the associated colliery owners has met the Minister of Railways for the purpose of pursuading him to maintain the special railway tariffs connected with the carriage of native coal over the State railways. Although they did not gain their point, yet they are in hopes that the Minister will consider their case at a future time in a manner more favourable to them. The transport of coal over the Belgian State Railways is increasing steadily. Last week 25,420 waggon loads were carried, as against 22,000 during the corresponding period of 1889.

THE IRON MARKET.—At the recent meetings of the iron-masters of Belgium, the good position of the market has been continually upheld and prices have been marked by firmness. Eighteen francs is the minimum price for merchant bars, and for girders and joists 18fr. have been demanded on home orders and 17·50fr. for foreign orders. As regards plates, 22fr. may be considered as a minimum, and angles are at a basis price of 19fr. At all the works there is plenty of employment on all the branches of manufacture. Native pig holds its price well, and there is no stock to speak of.

THE GLASS TRADE.—The price of window glass is maintained at a fairly satisfactory level. Several good sales have been made to the United States, England, China, &c. The statutes of association of the syndicate for controlling the sale of window glass to the United States have now been settled, so that the syndicate will be in full working order shortly. The sales will be concentrated in the hands of a committee of the glass association.

BELGIAN REVENUES.—During the month of November last the receipts of the State Railways amounted to 11,484,276fr., being an increase of 650,000fr. over the income during the corresponding month of 1888. The income of the post office was 1,277,398fr. during the same month, an increase of 40,000fr. over that of November, 1888. The income of the telegraphs has increased during the same period by 39,700fr., being 313,905fr. during November, 1889.

DÜSSELDORF, 4TH MARCH, 1890.

COAL.—The all-absorbing question of the hour is that of the coal supply. What is to come of the threat of the miners to strike for an advance of 50 per cent. in the rate of wages does not yet appear with certainty; but even if wiser counsels prevail, and production be continued at the present rate, the difficulties of the situation will not be easily overcome. The output of the blast furnaces is still restricted by the want of fuel, and manufacturers of all classes are complaining of the insufficient supply as well as of the high prices of coal. In Upper Alsatia the stocks in hand will, we are told, be exhausted in a few weeks. Representatives of the manufacturers in that locality are being sent into the Saarbrück mining district to buy coal for immediate delivery. There is, however, but little available, and consumers are compelled to resort to Belgian and English merchants. A meeting of the coal merchants trading with Holland was held at Ruhrort the other day, at which it was decided to form a strong syndicate to control the markets till the end of the current year. No alteration was made in the prices agreed to at the former meeting.

IRON.—The tone of business in the iron market is certainly very different from what it was a few weeks ago. Confidence in the stability of the situation has been shaken. Now that the excitement has subsided, people are better able to appreciate the prospect, and for many it has lost its enchantment. The fact that English, and even French, iron is being offered in the markets of Germany from 5s. to 10s. a ton below the prices of home-made iron has a significance not easily explained away. The difficulty is how to reduce prices now that the raw materials of manufacture have so greatly increased in cost, and with a prospect of yet dearer coal and labour this difficulty appears insurmountable. Hence the feeling of anxiety that prevails. That the margin for profits will have to be cut down no one doubts, and already there are signs of a retrograde movement in the prices of iron. Pig iron has given way a little. The apprehensions of manufacturers are significantly expressed in the downward course of all industrial securities, but especially shares in collieries and iron and steel works.

LILLE, 4TH MARCH, 1890.

IRON.—The iron industry of this locality is suffering much from the short supply of coal. It is not easy to account for this deficiency, for the iron trade is not exceptionally active, and the consumption of coal in other manu-

Digitized by Google

facturing industries cannot be much above the average. The scarcity exists, however, and the forgemasters are in consequence unable to deliver within the limits defined in their contracts. There is a falling off in fresh orders, but the syndicate rates are firmly adhered to. Finished iron from this district is now being offered in Germany at prices considerably below those of German iron. It is hoped that a good business will be done with German customers in the course of the coming summer.

TEXTILE MANUFACTURES.—Business in linen goods continues fairly active, but there is a want of vigour in the market, which, however, is not unusual at this time of the year. Paris houses continue to buy freely, but provincial orders are scarce. The statistics of trade in 1889 show the total amount of linen cloth sent away from the mills in the Armentières district to have been 323,286 cwt., a quantity slightly below that of the preceding year. Business is quiet in woollen goods at Roubaix. A committee of manufacturers, composed of twenty members representing every branch of the local industry, has been formed to protect the interests of the Roubaix woollen trade.

FLAX AND YARNS.—The demand for home-grown flax is fairly good for the season; but prices tend in favour of buyers. A large amount of business has been transacted in Russian flax. The demand is, however, scarcely so strong as it was a week ago. Prices have receded a little within the last few days. Tows are but little inquired for. Only the better qualities have found buyers. Spinners having made a small concession in prices, buyers have operated more largely this week, chiefly in wet spuns. The market continues very active for jute yarns at full prices.

AMSTERDAM, 3RD MARCH, 1890.

PATENTS IN HOLLAND.—Although an association has been formed, under powerful patronage, to re-enact the former patents legislation abolished some years ago, yet there is also a fierce resistance against the movement in some quarters. Many oppose a new patents law on theoretical grounds, holding that patents are useless and only afford a sham protection to the inventors who invoke them, but the objections of others, principally manufacturers, are founded mainly upon selfish grounds. They are working foreign patents without having paid for them, and now consider it a "hard thing" that they should be compelled to become honest again. The extent of Dutch manufacture of articles patented in other countries cannot, perhaps, be exactly known, but there is no doubt that it is greater than many imagine, and if patents were re-introduced it is certain that many industries would at first suffer. Therefore it would be wise to allow a certain lapse of time before the re-enforcement of the former legislation.

THE HARBOUR WORKS OF AMSTERDAM.—The new harbour works on the Y were recommended to centralise the transit trade of the capital under a Harbour Board. The Chamber of Commerce of Amsterdam has passed resolutions in support of the commission's recommendations, with the exception of that part thereof in which the appointment of a new committee is suggested to work out the plans laid down. The Chamber of Commerce has expressed a strong opinion that the existing commission ought, with the assistance of experts, to continue and, if possible, complete the task committed to it. The same Chamber has resolved to petition the States-General against the proposed re-imposition of an import duty on foreign grain, flour, and various cereals.

THE DIAMOND INDUSTRY OF AMSTERDAM.—The distress among the diamond cutters and polishers of Amsterdam, once one of the wealthiest classes of the community, still continues, on account of the dearness of the rough stone and the unwillingness of manufacturers to work upon the large scale of former days. Thousands of artisans are idle and nearly starving. They have appointed a committee, with the object of putting an end to this crisis. From a programme issued by the committee it appears that it is proposed to form an international association of jewellers, and of cutters and polishers of precious stones, strong enough to control the markets and narrow the exorbitant margin between rough and polished stones at present existing. The same association would have to support the efforts now being made to secure a legal working day of eight hours. It is likewise suggested by the committee abovementioned to start in Amsterdam a diamond bank, with a capital of £2 000,000, or even a little more. The Communal Council of Amsterdam has been appealed to by the committee for practical help, but it has said that it cannot see its way to way to do so.

BUTTER AND MARGARINE FACTORIES.—The number of butter factories on the Danish system is rapidly increasing in Friesland. In many villages, where already one factory existed, a second one is being erected, mainly by small companies or wealthy dairy farmers. In this system the milk is collected from various farms around the factory, where it is tested and mixed together. The butter produced is also combined with butters made in the neighbourhood, and thus equality in make and grade is constantly assured. Meanwhile, the new Margarine Act has not stopped or even impeded the important industry of butter substitutes, which still extends in every direction. The quantity of margarine manufactured last year in Holland is by far the largest ever produced in this country. A new factory has just been started by a company in Rotterdam with a capital of £100,000.

THE PORT OF ROTTERDAM.—It has been proposed to make Rotterdam a port of call for the boats of the subsidised line of steamers between Hamburg and East Africa, to be established as soon as the German Reichstag shall have passed the Government proposals as laid down in a Bill. This project has created much sensation in Rotterdam, where the communal authorities and the Chamber of Commerce have been hard at work to elaborate and forward to Berlin full particulars anent the port, its river accommodation, and the progress of the new waterway to the Hock van Holland. Various towns in the Rhenish provinces have also petitioned the German Government and the Reichstag in support of the claim of Rotterdam.

COPENHAGEN, 1ST MARCH, 1890.

NEW BREWERY IN SWEDEN.—Although brewing may have been overdone in some parts of the world, it is hardly the case in Scandinavia, where not only are the old-established breweries doing very well, but the erection of new ones is going on continually. Mr. A. Richter's brewery at Malmö, Sweden, is just about ready to commence work. A good site has been secured, and the interior arrangements are up to the requirements of advanced brewing. There are four large store cellars, and four yeast compartments, with 32 yeast vats. The front of the brewery is 240ft. long, and the depth of the cellars 17ft. underground. The ice reservoirs have a very considerable capacity.

NORWEGIAN SALVAGE STEAMERS.—The question of stationing salvage steamers on the Norwegian coast has been much discussed of late, and numerous voices have been raised urging the Government to take up the matter. The Government has asked for opinions from various institutions. An opinion of some weight has just been received from the Hangesund Nautical Society, recommending the building of three such steamers at a cost of about £10,000 each. They should be stationed respectively at Christianssand, Egersund, and in the vicinity of Bergen. It is also recommended to build ten life-boats, at a cost of £275 each, mostly intended for the protection of fishermen along the Norwegian coast.

BRITISH TRADE WITH NORWAY.—British trade with Norway is progressing in a most favourable manner. In 1887 it occupied the first place both in imports and exports, and in the succeeding year this position was more than maintained, although the total value of the foreign trade of Norway increased from £13,351,000 in 1887 to £15,600,000 in 1888. It should be mentioned that, for statistical purposes, Sweden is treated as a foreign country. Great Britain took 32·5 per cent. of the total exports of Norway in 1888, Sweden coming next with 13·9, then Germany with 13·3, Spain with 8·6, and France with 7·3. Of the total imports this country sent 27·9 per cent., Germany 26·9, Russia 13, and Sweden 12·3. The exports are mainly timber and fish, and, in connection with the former, it is interesting to note the extraordinary increase of the trade in wood pulp and cellulose, which in 1875 amounted to 8,540 tons, valued at £38,000, and in 1888 was 162,455 tons, valued at £510,000. The chief imports are grain and flour, manufactured and colonial goods, in the last of which especially there was a very considerable increase in 1888.

CEMENT MANUFACTORY IN SWEDEN.—Among the industries which have shown exceptionally rapid growth in Scandinavia during the last two or three years is the manufacture of cement. One of the newest works is the one at Limhamn, Sweden, which is just about to begin operations. The method of manufacture will be considerably simplified. The lime and the clay are conveyed into the building, where they are ground together in mills, with ordinary stones, to a certain degree of fineness. This substance is then made wet, and afterwards pressed into bricks. These are afterwards dried so as to remove the remaining moisture. The next process is the burning, and the produce is what is termed "raw cement." This is now conveyed to another part of the works, where it is ground and sifted, and afterwards conveyed to the stores to be packed.

MADRID, 3RD MARCH, 1890.

COKE MAKING AT BILBAO.—The large Bilbao establishment of San Francisco, which has been known as the Marquis de Mudela's works, has entered into a contract with M. Coppée, of Brussels, for the erection of a coke-making plant, with all his latest improvements both in furnaces and coal-washing devices. So far it is not intended to take advantage of bye-products, but the idea is to have as much gas as possible for raising steam. It is a great mistake not to give a preference to the systems which reduce the cost of coke by the sale of tar and ammonia.

CORUNNA WATERWORKS.—The municipality of Corunna is inviting tenders to carry out the supply of water to that important town. The cost of the works will be a little over £100,000, and the concession, which is on very reasonable conditions, will last ninety-nine years.

CADIZ SEWERS.—A scheme for remaking the old and badly kept sewers of Cadiz is engaging official and public attention, and a contract for reconstruction is to be arranged with some English capitalists.

STEEL-MAKING AT TRUBIA.—The Siemens 10-ton furnace, which has been building for some months at the ordnance works at Trubia is now nearly completed, and the question at present is to obtain a good practical smelter to instruct the local men in the management of large furnaces. The furnace will be ready for starting in four or five weeks.

THE PRICE OF ELECTRIC LIGHT.—The circulars of the English company, "The Electrical Supply of Spain," giving the prices, &c., have been issued. Their rate is enormous, but it is quite natural that they should try to get such prices, as gas is 9s. per 1,000 cubic feet. The Berlin company, which is to carry on business under the name of Compania Madrileña de Electricidad, has not published their price, but it will be very high. This state of things will last until the public find out that their prices are exorbitant, and encourage private installations.

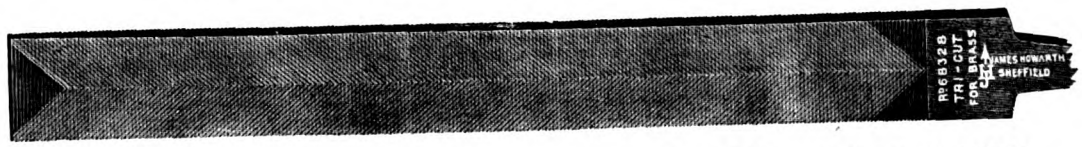
NEW YORK, 22ND FEBRUARY, 1890.

THE COAL TRADE.—The weekly production of anthracite is now about half a million tons, and will probably remain about that figure for some time. Ordinarily about this time of year there should be a considerable demand for domestic sizes, but at present it is very light, for consumers either have a considerable supply on hand or are concluding that the severe weather is over. There are rumours of a strong combination to restrict the production and maintain prices. There ought to be no trouble in making the trade for the year a fairly profitable one, and a combination which would prevent ruinous cutting of prices would result in a fair year's business. Several of the leading companies propose opening large coal yards in the chief cities, thus cutting out the middlemen in the trade.

A LARGE CONTRACT.—The contract for a portion of the Chicago elevated road has been let to Carnegie, Phipps, & Co., of Pittsburg. It is for three and one half miles of road. The contracting firm will turn out the material at the Union Iron Mills. To erect the track contracted for will require about 8,000 tons of iron shapes. The iron used in the Brooklyn "L" roads, after which the Chicago road is patterned, cost between $80 and $100 per ton. A fair estimate as to the cost places it at from $800,000 to $1,000,000. The firm will complete the first mile by March 25th, and the entire work contracted for will be finished by July.

A LARGE MACHINE.—The Miles tool works, of Hamilton, Ohio, have finished and are now loading a large armour-plate bending roll, that is to be sent to the navy yard at Mare Island, Colo. The machine weighs somewhere near 400,000lb., and the freight will cost over $10,000. The Cincinnati, Hamilton, and Dayton Railroad has had a number of special flat cars built to carry the machine, and the train will be run through as a special. It is the largest single shipment, and is said to be the finest machine that ever left Hamilton, a town that sends out a great quantity of magnificent machinery.

THE NEW SHIPYARD.—Nearly a year ago it was stated that the Pennsylvania Steel Works at Sparrow Point, Md., would ultimately include in its business the making of heavy guns and the building of steel steamships, and plans are about completed for carrying this into effect. The first work to be done in the proposed shipyard will be two steamships for the steel works company, to be used in the iron ore trade with Cuba. Every movement of the company in increasing its machinery for the reduction of ore to iron and steel has had in contemplation the eventual capability of turning out all sorts of shapes, so that every part of a ship can be built in their own works. The superintendent says that the company will confine itself at first to building coastwise steamships, but a general business in competition with foreign shipbuilders was what they expected to end with, and he thought it possible for steamships to be turned out as cheaply here as abroad.



"THE RAPPAHANNOCK."—The new ship "Rappahannock," the largest wooden vessel ever built in this country, arrived in Philadelphia last week on her first voyage from Bath, Maine, where she was built at a cost of $125,000. She is 287ft. long, and 48¾ft. beam; her draught (loaded) is 28ft., and her tonnage 3,053 net. She is built of oak frames and Georgia pine ceiling and planking. She will load 1,200,000 gallons of oil in cases for Japan, the largest cargo of the kind ever exported.

CHESAPEAKE AND OHIO EXTENSION.—President Ingalls, of the Chesapeake and Ohio Railway, says it is a part of the plan of the company, in availing themselves of the franchises recently granted them by the General Assembly of Virginia, to establish lines of steamers between Newport News and New York to Liverpool. They also propose to build several branch roads through Virginia. The net earnings of the system for this fiscal year will reach seven million dollars, and could have been made much higher if they had the facilities to handle the business tendered them. The line was never in as good condition as at present. Two years ago there were seventy-three trestle bridges on the road, and to-day there is but one, and an iron structure is to be put up at this point.

READING IRON WORKS.—The directors of the Reading Iron Company met in Philadelphia recently, and decided to increase the capital from $300,000 to $1,000,000. The company, which less than a year ago was obliged to close down, is again on its feet, with good prospects ahead of it. The creation of the additional capital was to improve and repair the works, to acquire additional furnaces, and to provide sufficient working capital. The directors a short time ago secured control of the two Keystone furnaces, having a capacity of 500 tons, and which cost $500,000. With the enlarged stacks and new hearths the output is expected to reach 900 tons. The number of men employed in the different departments of the work is now over 2,000, and if there is no decline in the iron market this number will probably be increased to 3,000.

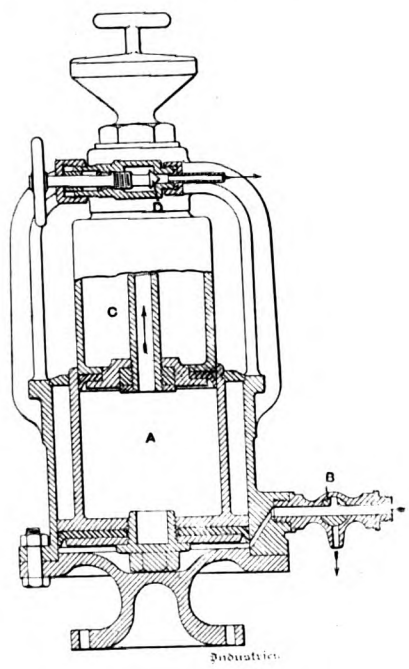
HOWARTH'S TRI-CUT FILE.

IMPROVED DRAUGHTSMAN'S PROTRACTOR.

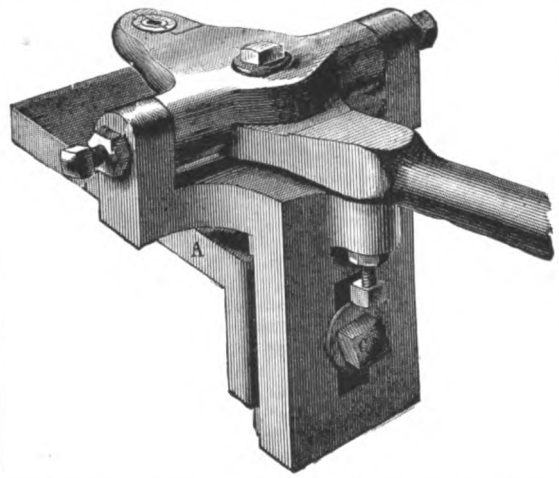


The accompanying illustration represents a new form of protractor which is being introduced by Messrs. Darling, Brown, & Sharpe, of Providence, Rhode Island, U.S.A. It is made from $\frac{1}{16}$in. sheet steel, and is, therefore, both light and durable. The protractor may be used

for laying off angles, dividing circles, &c., in conjunction with a T square or straight edge. It can be quickly and accurately set by hand to any desired angle, but a small lever is provided for very fine settings. As there are no projections on either face, it may be used either side upwards. The blade is $8\frac{1}{2}$in. in length.

A NEW LUBRICATOR.

In the issue of *Industries* of the 27th December, page 624, we described a new lubricant called "dynamine," which is now being made by La Compagnie Française des Graisse Minérales, and we now illustrate a lubricating apparatus which has been specially designed for the use



of this oil by M. Sanbenard. By a suitable arrangement of parts, a single lubricator is made to do duty severally in supplying oil to the cylinder, slides, bearings, &c. The cylinder A is filled with oil, and steam is allowed entrance underneath by means of the cock B. The piston C is fixed, and the cylinder A moves upwards under the force of the steam. The cock D regulates the rate of discharge of the lubricant. When the vessel A has been emptied, the three-way cock B is turned so that the water of condensation may be evacuated and a new charge of oil introduced through the screwed stoppers E.

HOWARTH'S TRI-CUT FILE.

We have carefully tried a new file now being brought out by Messrs. James Howarth & Sons, Broomspring Works, Sheffield. It is cut once straight across at right angles to the length of the file, and then each half is cut diagonally in different directions, as shown in the illustration above. An ordinary file has a tendency to slip off the work, and this has to be prevented by the workman. After some practice the workman counteracts this tendency unconsciously. Mr. Howarth's file, however, always tends to keep evenly over the work, and is therefore easier to use. It has no tendency to slip off the surface to be filed and make marks on some neighbouring place which has been already finished, and perhaps highly polished. The teeth are very clearly cut, and the file works well.

SCREW SLOTTING DEVICE.

We illustrate herewith a simple device for slotting the heads of screws, which can be attached to any ordinary hand lathe. The platform A is fastened to the bed by a bolt, and a long lever projects in front at right angles with the bed. A spindle carrying a circular cutter is held in the centres of the lathe. The lever is moved horizontally to open the jaws for inserting and removing

the screws, and downward to bring the screws to be slotted against the saw. The stop screw B governs the downward motion and regulates the depth of slot in the screw head. The working part of the apparatus can be raised or lowered on the platform front by means of the bolt C. This apparatus is made by The Brown & Sharpe Manufacturing Company, Providence, Rhode Island, U.S.A.

SOCIETY OF ENGINEERS.

At a meeting of the Society of Engineers, held on Monday evening, the 3rd inst., Mr. Henry Adams, President, in the chair, a paper was read by Mr. Ralph Hart Tweddell, M.Inst.C.E., on the "Application of Water Pressure to Machine Tools and Appliances."

The author referred to his previous paper read before the Society in 1877, and to the greatly extended adoption of his system of hydraulic machines and appliances during this interval. He gave figures showing the continually increasing power and size of this class of machines during the quarter of a century which has elapsed since he first introduced them, and very closely analysed the relative advantages of hydraulic, pneumatic, and electric transmission of power, considered in their special relation to working machine tools and the appliances in connection with taking the work to and from them.

The author, having emphasized the fact that the conditions to be fulfilled in the designing of a "complete system" of machine tools are very different from those affecting a "single machine," proceeded to point out the great number of conditions to be fulfilled by any motive power when applied to working machines varying greatly in their individual character and requirements. Dividing the subject of the relative merits of these three motive powers into (1st) the convenient storage of the power, (2nd) economy and facility in distributing the same over large areas, (3rd) simplicity in its application to machine tools and the appliances required to take them to and from their work, (4th) adaptability to perform work of the lightest and heaviest description, the author stated that, while electricity and air fulfil some of these conditions, they do not fulfil those of the most importance in connection with the class of work under discussion. On the other hand, hydraulic pressure not only fulfils all of the above conditions, but it is especially applicable to the working of machine tools and the appliances for lifting and transporting the materials operated upon by them. The author then referred to various improvements effected by himself and others in hydraulic machines now required to meet the altered conditions of riveting, flanging, drilling, &c., in order to make sound work in the heavy boilers now used with high steam pressure.

The author then proceeded to describe the riveting up of large bridges *in situ*, and referred to the first bridge so constructed, namely, the Primrose Street bridge, in London, which was riveted up on the author's system in 1873. After alluding to many other bridges, the author pointed out the absolute necessity of a largely extended use of labour-saving appliances in workshops, such as cranes, lifts, capstans, &c., which are necessary, not only on account of the greatly increased weight of the work now machined, but also to keep all classes of machine tools in more continuous work. In conclusion, he pointed out that hydraulic pressure was as suitable for working these appliances as for working the machine tools themselves.

SHIPBUILDING NOTES.

On the 19th ult. the s.s. "Eugenie," launched a few weeks ago from the shipbuilding yard of Messrs. Richardson, Duck, & Co., was taken to sea for a trial of her machinery. The engines are of the triple-expansion type, and have been built by Messrs. Blair & Co., Ld. The cylinders are 21½in. 35in., and 57in. in diameter, by 36in. stroke. The machinery worked very satisfactorily during the trial, but owing to the heavy sea no speed results could be obtained.

On the 19th ult. there was launched from Messrs. Craig, Taylor, & Co.'s. Thornaby Shipbuilding Yard, Stockton-on-Tees, an iron screw steamer of the following dimensions: Length, 278ft.; breadth, 37ft.; depth, 19ft. 8in. The vessel has been built with a long raised quarter-deck, bridge extending to and including foremast and forewinch, short well and topgallant forecastle. She is fitted with web frames in the after-hold, and has a double bottom for water ballast. She will be fitted with four steam winches by Messrs. Robert Roger & Co., of Stockton; steam steering gear by Messrs. Alley & Maclellan, Glasgow; patent windlass by Messrs. Emerson Walker & Thompson Bros., Gateshead; Messrs. Hastie's screw gear aft, and all modern improvements, so as to admit of rapid loading and discharging. The engines, on the triple-expansion three-crank system, are being constructed by Messrs. Westgarth, English, & Co., Middlesbrough-on-Tees, and have cylinders 20in., 33in., and 54in. in diameter, by 36in. stroke. As she left the ways she was christened "Shaftesbury."

On the 20th ult. Messrs. Edward Withy & Co. launched from their yard at Hartlepool a large iron screw steamer, built to the order of Messrs. Burdick & Cook, of London. The vessel has a long raised quarter-deck, short poop, long bridge-house, and a topgallant forecastle. The holds are fitted with iron grain divisions, and all decks, deck erections, skylights, bulwarks, bulkheads, &c., are constructed of iron. In the main and after holds the vessel is built on the web-frame system. The cellular bottom is fitted all fore and aft for water ballast. Four steam winches, large donkey boiler, patent steam steering geer amidships, screw gear aft, patent steam windlass, stockless anchors hauling into hawse pipes, and other modern appliances are fitted for the handy working of the vessel. On leaving the ways the vessel was christened "Amie."

On the 22nd ult. the steamer "Coomassie" was launched from the yard of the Naval Construction and Armaments Company at Barrow. She has been built for Messrs. Elder, Dempster, & Co., of Liverpool, and is 312ft. long, 39ft. beam, 27ft. 6in. deep. The engines are of the triple-expansion type, and have cylinders 23in., 38in., and 62in. diameter, by 42in. stroke. Steam is supplied from two single-ended boilers 14ft. 6in. diameter and 10ft. 6in. long, with 160lb. per square inch working pressure.

On the 22nd ult. Messrs. Workman, Clark, & Co., Limited, Belfast, launched a steel screw steamer named "Chichester" for Mr. W. R. Rea, Donegal Quay, Belfast. Her dimensions are:—Length, 285ft.; breadth, 38ft.; depth, moulded, 22ft. 2in. She is a well-decked steamer, with topgallant forecastle, short well at fore hatch, long bridge-deck, and raised quarter-deck. The decks are of steel, and there is a cellular double bottom all fore and aft. She is schooner rigged, with steel masts and square sails on the foremast. The engines and boilers are being made by Messrs. Muir & Houston, Glasgow.

Digitized by Google

On the 22nd ult. Messrs. Harland & Wolff, Limited, Belfast, launched a large four-masted steel sailing ship for Messrs. Ismay, Imrie, & Co., Liverpool. This vessel has a registered tonnage of over 3,000 tons. Her dimensions are:—Length, 318ft.; breadth, 45ft.; depth of hold, 26ft. 6in.

Notices of Meetings.

NEXT WEEK.

Institution of Civil Engineers.—Ordinary meeting, Tuesday, March 11th, at 8 p.m. Discussion upon the papers by Messrs. Burge, Walton, and Cruttwell on the Hawksbury, the Dufferin, and the Blackfriars Bridges.

Society of Arts.—Wednesday, March 12th, at 8 p.m. "The Chemin de Fer Glissant, or Sliding Railway." By Sir Douglas Galton, K.C.B., D.C.L., F.R.S.

Institution of Electrical Engineers.—Thursday, March 13th, at 8 p.m.. Adjourned discussion on the following papers: "The Theory of Armature Reactions in Dynamos and Motors," by James Swinburne; and "Some Points in Dynamo and Motor Design," by W. B. Esson.

PRICES CURRENT, 5th March, 1890.

Quotations at per ton, unless otherwise specified.

Tin: Straits	89	17	6	"	90	5	0
" Australian	89	15	0	"	90	5	0
" English Ingots	95	0	0	"	.....		

Messrs. Carrick & Brocklank, Manchester, report as follows:—

Copper: There has been but little variation in prices of Chili bars during the past week, the market having been pretty steady and free from important fluctuations. The general uncertainty in the metal markets deters buyers. The stock of copper on 28th February was returned as 95,152 tons, the decrease during February having been but slight. Manufactured continues in slow demand, quotations being—sheets £63, bottoms £66.

Tin remained very quiet up to the end of last week, but on Monday there was a strong market, prices advancing from £89 15s. to £90 17s. 6d. cash. The advance, however, was not maintained, and quotations to-day are the same as in our last report—viz., £89 17s. 6d. to £90 5s., with an active business.

Lead: A quiet market has been experienced during the week, and prices have declined somewhat, to-day's London quotations for English being £12 10s. to £12 15s., with foreign £12 7s. 6d. to £12 10s.

Spelter continues very firm, the stocks being small.

Messrs. S. W. Royse & Co., Manchester, report as follows:—

Chemicals.—There is still a scarcity of new business, but old contracts are keeping manufacturers well employed, and prices remain steady. Bleaching powder is, perhaps, a little easier for spot delivery; on the other hand, soda ash is a little dearer. Sulphate of copper for early delivery is a little easier, and there is not the same disposition to buy forward. The demand for green copperas has ceased, with a fair number of orders for forward. Sulphate of ammonia is more pressed, but prices remain fairly steady.

FOREIGN TELEGRAPHIC ADVICES.

(From our own Correspondents.)

Paris, March 6.—*Iron.*—The market here continues somewhat weak. Merchants refuse, however, to sell bars below 160s. and joists below 164s. The provincial markets are steady, but they have lost something in buoyancy. A better tone prevails in the Loire-et-Centre. In the Haute-Marne the demand for wire, wire nails, and chains continues unabated. In the Nord business is active and prices are firm.

Metals.—The metal market continues steadily its downward course, copper leading the way. Chili bars are now quoted at £52 and less; best selected, £56. Banca tin has dropped to £98 10s. and Straits to £96. Lead is a point lower, £12 16s. Spelter has recovered a little; Silesian, £25 5s.

Berlin, March 6.—*Bourse.*—The continued downward tendency of all industrial securities shows that confidence has been rudely shaken. Within the last few weeks colliery companies' shares have dropped at least 35 per cent. In some instances the fall has been much greater—up to 90 per cent. Iron and steel companies' shares have followed the collieries at no great distance. Prices further receded yesterday. To-day the market opened weak.

Iron.—The market has lost a little of its activity, and prices are less buoyant. Silesian bars are quoted 205s. to 210s. a ton. Buyers hesitate to operate for forward delivery. Fear of labour disturbances is visibly checking the current of trade.

Metals.—The metal market is lifeless. There is very little buying of anything, and prices are made the subject of much bargaining. Copper is very dull: Mansfeld refined is still quoted £59 to £60, but English brands have receded a point to £56 to £58. Tin is also a point lower: Banca, £100 to £102. Lead is firm: Clausthol refined, £15 10s. to £16. Spelter is a shade better: Silesian W.H. brand, £25 15s. to £26 10; ordinary, £24 15s. to £25 10s. Antimony regulus firm.

Breslau, March 6.—*Iron.*—The market continues active, but the upward tendency of prices is disappearing under the influence of foreign competition. English pig is being offered at 66s. a ton on trucks at railway stations in Upper Silesia; and French bars are offered by a Hamburg firm at 190s. delivered free either at Beuthen or at Kattowitz. Joists are in brisk demand. Bars are quoted 210s.; boiler plates, 250s. to 260s.; and thin sheets from 255s. to 265s. a ton.

Metals. Contrary to expectation, the market for zinc has lost in firmness within the last day or two in consequence of the Silesian Mining and Zinc Manufacturing Company having pressed for sale some old stocks of spelter. The weakness thus occasioned is not likely to be of long duration. "Bear" speculators are making the most of this circumstance. Lead remains moderately firm. The demand is sufficient to absorb the whole of the production.

Düsseldorf, March 6.—*Coal.*—The market keeps steady. Sellers refrain from forcing up prices in view of the threatened strike of colliers, in order not to provoke that movement. The sharp weather of the last few days has given a fillip to the trade in household coal. The supply of coke is still short of the current requirements of consumers. Belgian coal is arriving in larger quantity.

Iron.—The demand for pig iron is slack, and the tone of the market hesitating. Some lots in the hands of speculators have been sold at lower prices to close accounts, but manufacturers maintain their rates firmly. The market for finished iron and steel is a little less active. The demand for joists has fallen off. Business is being checked by apprehensions of labour disturbances. Prices are unaltered. Export trade very quiet.

Charleroi, March 6.—*Coal.*—The market has not yet returned to its normal state, a circumstance largely due to the uncertainty of the situation in Westphalia and in England. Coke is still quoted 28s. a ton. Foreign orders are coming to hand in abundance. There is a good deal of buying on Portuguese account, a consequence of the ill-feeling against England in Portugal.

Iron.—Business is not brisk, but inquiries are more numerous. Prices are firmly maintained. English-buying orders for joists are coming to hand freely. Offers of 175s. a ton from English houses for large quantities have been refused. Makers' prices are 185s. The tone of the pig iron market is strong.

Glass.—Makers complain of the insufficiency of the demand to absorb the production. The market is slack. Some important New York orders have, however, been received within the last few days, and others are in sight. The new glass manufacturing company, whose works are to be situated between Roux and Gosselies-Courcelles, has been formally constituted.

Ghent, March 6.—*Flax and Yarns.*—The demand for home-grown flax being brisk, and the quantity on offer somewhat less than it was a week ago, the tone of the market is stronger. In Russian very little doing. The demand for yarns is sufficient to enable spinners to maintain their prices without much difficulty.

Proposed New Railway in Denmark.—The Danish Government has introduced a Bill into Parliament about the construction of a new railway along the coast of the Sound to Elsinore. There is already one railway between this town and Copenhagen, but the new one will form a continuation of the present Klampenborg line. The length will be about 25 miles, and the cost is calculated at 4,100,000kr., and 920,000kr. for rolling stock, &c.

Black Granite in Sweden.—In the vicinity of Varberg "green" granite has for several years been a favourite specialty, and found an extensive sale both at home and abroad. Of late black granite has superseded it. Black granite had, however, to be brought from distant parts, but an important discovery of this stone has now been made on the Brunnsberg estate, a find which will, no doubt, prove of great value, and which has already attracted considerable attention.

HOME INDUSTRIES.

LONDON 6TH MARCH, 1890.

THE MONEY MARKET.—The money market has been very easy all the week in anticipation of a further reduction in the Bank minimum. Rates have fallen. The only thing which menaces the market is the probability of gold exports to New York. The exchange has been steadily going against us for some time, and now the point has been reached at which it will pay the Americans to import specie from London. Although the Bank's position is strong and the market is well supplied with money, this probability causes some little apprehension. The stock markets have been very dull. Consols improved in the beginning of the week on buying for the Sinking Fund. Home railways have been depressed, partly because of the disappointing dividend declared by the Caledonian, which was ¼ per cent. below expectation. American railways are an uncertain market, brisk one day and depressed the next. Foreign stocks have been comparatively lifeless, with the exception of Argentine securities, which have fallen heavily in response to a sharp upward movement in the premium on gold at Buenos Ayres. Industrial and miscellaneous securities have been quiet, but the shares of the Salt Union have had a fair recovery. Copper shares are out of favour, and gold mines are altogether neglected. The nitrate group has experienced another relapse.

COMPANIES.—The following companies have been registered since our last report:—The Reliance Portland Cement Works, Ld., with a capital of £60,000; Boschkop Silver Mining Co., Ld., with a capital of £100,000; The Victoria Mill (Clayton-le-Moors) Co., Ld., with a capital of £9,000, to carry on the business as cotton spinners, &c.; Pahang-Semiliang, Ld., with a capital of £200,000, to acquire lands and mines in the Malay Peninsula or Archipelago; The Brownmills Patent Manhole, Gully, and Grate Co., Ld., with a capital of £2,500; Harvey, Graham, & Co., Ld., with a capital of £15,000, to carry on the business of engineers and machinery exporters; The Blyth and Tyne Brewery Co., Ld., with a capital of £60,000; The Forest of Dean Wagon Co., Ld., with a capital of £5,000; The King's Norton Metal Co., Ld., with a capital of £140,000, to carry on the business of manufacturing metal sheets and other articles; The Penjom Pahang Gold Co., Ld., with a capital of £190,000; The Richmond Ironworks, Ld., with a capital of £25,000, to acquire interest in rolling mills, &c.; Bournehills and Withymoor Collieries and Fire Clay Co., Ld., with a capital of £15,000; Bonnick & Co., Ld., with a capital of £2,000, to carry on the business of machinists, &c.; Robert Walker & Sons, Ld., with a capital of £50,000, to acquire the Providence Cotton Mill, Hyde, Cheshire; Appleton, French, & Scrafton, Ld., with a capital of £160,000, to carry on the business of flour millers and corn factors; Le Champ D'or French Misgund Gold Mining Co., Ld., with a capital of £100,000; The Cortex Calorifuge Co., Ld., with a capital of £10,000, to manufacture, deal in engines, &c., for ships; Sharp Murray Ld., with a capital of £20,000, to acquire the bleaching and dyeing business carried on at Park Mills, Bradford; Henry Lister & Son, Ld., with a capital of £80,000, to carry on the business of worsted spinners, &c.; The Italian and General Exploring Co., Ld., with a capital of £5,000; The Montgomeryshire Brewery Co., Ld., with a capital of £70,000; The Ruby Mining Co., Ld., with a capital of £100,000, to acquire mines at Eureka, Nevada, U.S.A.; Toms & Co., Ld., with a capital of £22,000, to carry on the business of brewers.

SHIPPING.—Freights have inclined to a lower level all round, which, in conjunction with the higher and increasing cost of working steamers, makes it a difficult matter to secure anything like good profits on any round voyage. The first two months of the year has been time lost to many steamers. Out-freights in all directions have come to a very low ebb, and are difficult to secure. Wages are still high, and especially in the outports. In shipbuilding there is an appreciation of the danger of further increasing the present over-supply of tonnage, and fresh orders are scarce. Shipbuilders are actively prospecting for new work, and several own to having booked nothing this year.

COPPER.—Good merchantable copper has declined £2 per ton during the past month. This was due to the number of warrants on the market and the difficulty of financing them with the Bank rate at 6 per cent. From £49 on the 1st ult., sales were made down to £46 15s. on the 11th, from which point there was a reaction to £48 12s. 6d. on the 17th, but values subsequently receded to £46 12s. 6d. on the 24th, closing with buyers at £47 cash and £47 12s. 6d. three months' prompt. Furnace material has only been sold to a limited extent, but at full prices. Holders are firm and expect that smelters will shortly have to replenish their stocks. Recent sales of American matte have been chiefly to sulphate of copper manufacturers, for which there has been a very strong demand at high prices. American supplies have been much less than usual.

GOVERNMENT CONTRACTS OPEN.—The India Office is seeking tenders for four spans of 60ft. roadway bridges for the Assam Public Works, Khasi and Jaintia Hills division, one span of 65ft. roadway bridge for the Basu Nala Bridge for the service of the North-West Provinces and Oudh Remittance Provincial Funds Public Works, and five bridge piers, two being abutment piers and three intermediate piers, for the four spans above-mentioned. The three tenders are independent, but are all to be handed in at the India Office not later than the 11th inst. The usual stipulations as to tests, quality of work, delays, &c., are embodied in the specifications. Each contractor is required to give a price for delivery at London, Liverpool, and one other port. The bridge piers are formed of screw piles connected by couplings, and braced together with angles tees, and plates. The material may be either of wrought iron or mild steel for the round iron piles and bracing, but the screws are to be of cast iron. The approximate quantities are 17 tons in one intermediate pier, and 5¾ tons in one abutment pier. The total weight is to be 63 tons 13 cwt. The 65ft. spans are formed of lattice main girders, with cross girders and trough flooring. The top booms of main girders are of 10in. by 3½in. by ½in., the bottom of plates on edge being stiffened with zigzag bracing. The approximate weight for one span is 24¼ tons. The 60ft. span is of similar construction to the 65ft. spans, with the exception that the main girders are of the Whipple-Murphy type, with swelled links and pin connections for the bottom boom. The top boom is to be of channel iron. The approximate weight is 24 tons for this span.

A NEW FRESCO CEMENT.—On the 5th inst. Mr. Edwin Lucas read a paper before the Civil and Mechanical Engineers' Society on a new medium for fresco painting, called "Fresco Cement." The composition, invented by Mr. Kremeyer, consists largely of tufa, together with Portland cement and lime, and the patentee claims for it that, being hydraulic, absorptive, and acid-proof, it is absolutely unaffected by the severest climate. He quoted a favourable report from Mr. H. Faija, M.I.C.E., who tested the strength of specimens which had been immersed in water for 28 days. The average tensile strength of five specimens was found to be 312lb. per square inch.

THE SANITARY INSTITUTE.—The Council have accepted an invitation from the Town Council of Brighton to hold the autumn Congress and Health Exhibition in that town in September next.

MANCHESTER, 6TH MARCH, 1890.

THE COTTON TRADE.—In giving evidence before the Royal Commission on Railway Rates, Mr. S. Andrew, the Secretary of the Oldham Cotton Spinners' Association, stated that about £67,000,000 of new wealth was created by the cotton trade every year. The cost of the cotton used up in this country was £35,000,000, and the value of the manufactures exported was £72,000,000, and £31,000,000 was sold in this country. The charge for terminals was strongly objected to, and it was shown that the Continental rates were much lower than in this country. The increase in the number of spindles in this country was only 500,000 from 1884 to 1889, while the number of spindles abroad were larger by 3,000,000. Any addition to the burdens for carriage would be very prejudicial to the interests of the whole body of spinners.

THE SALT TRADE.—The exports of salt have shown a large increase during February, having risen from 37,578 tons in the same month last year to 62,111 tons. These shipments are at the higher prices now ruling. In connection with this trade the Salt Union are boring in the Cheshire district in order to ascertain whether there are minerals below the salt beds. It is intended to bore 3,000ft. to 4,000ft. to ascertain whether coal exists at that depth.

THE IRON TRADE.—There is considerable hesitation in the market here as the disparity in the prices of warrants and makers' iron continues. There has been an undoubted slackness in the number of orders, which have neither been large or numerous. Makers are disposed to meet the market for good orders, but there are not many of these moving. Most consumers are well bought and are not inclined to buy so long as warrants remain at present rates, believing that there will be rather a fall of the price of iron than an advance in that of warrants. Finished iron is strong but it is principally because of old contracts which keep the works going fully. The general consumption in the district is good and regular, and there is no lack of specifications against contracts, but few of the latter are being made. Generally the tone is weaker, but merchants and makers look to the opening of the spring shipping trade to revive the demand.

HUMIDIFYING APPARATUS.—A new form of humidifier is being introduced for use in weaving sheds. The peculiarity of it is that instead of using live steam to effect the object, the vapour arising from the cooling tanks used for the condensation water is employed. The outlet of the pipes is covered by a chamber and a current of air is drawn through the chamber and propelled into the shed by means of a fan. The humidity is thus set up by vapour at a low temperature, and pure cold air is fed into the room. If condensation water is not used a dish or tray containing water can be heated by a small coke fire so as to emit vapour at about 110°. It is found that there is no dropping of water within the shed. The temperature and humidity can be accurately regulated, and the cost of live steam is entirely obviated. The inventor of the system is Mr. R. H. Neill, King Street Flour Mills, Belfast.

THE LINEN AND JUTE TRADES.—The business passing in the local wholesale dry goods houses is brisker, although rain and bitter cold on Tuesday kept many buyers away. Pale roughs are selling at prices lower than ever before known, and were it not for the plentiful and cheap supply of suitable flax the trade would, from the manufacturers' point of view, be in a very desperate condition. An active inquiry for linen yarns which are used for the backs of Brussels carpets prevails in Kidderminster, 3's, 4's, 5's, and 6's being the favourite counts. Handkerchiefs, which have had a good run, still continue in active request, and several representatives of Manchester houses engaged in the linen and cotton departments of the business left for New York by the "Teutonic" the other week, so that orders from the other side may be expected to arrive ere long. Prices are rather lower for linen handkerchiefs, although wages have advanced and cost of production generally tends upwards. Hessians are slow. Jute goods generally will, it is hoped, command better rates shortly. Fancy varieties are selling well, and jute Brussels maintain their hold upon public favour. The advances which have been made by designers and others engaged in this branch have been considerable during recent years, with the result that the public have taken much more readily to the goods.

IMPROVED BELTING.—Messrs. Greenwood & Co., Limited, of Todmorden, are introducing a new kind of belt, for which many advantages are claimed. It consists of a thin layer of buffalo hide, covered on each side by woven cotton or hair belt. The edges can be formed so as completely to resist wear by a strap fork, and this special variety is in demand for mule driving. The makers claim great driving power for the new form of belt, which possesses the advantages of strength arising from the use of the buffalo hide, and the adhesiveness and wear of the woven belts.

GLASGOW, 6TH MARCH, 1890.

ENGINEERING.—Messrs. William Simons & Co., Renfrew, have secured a contract with the Mersey Docks Board for the supply of a set of powerful sand pumping apparatus. The machinery is to be employed in cutting a deep channel through the Mersey bar, and is to be fitted on to one of the steam hopper barges which was built for the Board some time ago by the same company.

SHIPBUILDING.—A contract for two steel screw steamers has been secured by Messrs. Murdoch & Murray, shipbuilders, Port Glasgow. Both vessels are intended for the fruit trade between America and the West Indies, and are each of 175ft. keel and about 500 tons gross register. They are to be supplied with triple expansion engines of 800 i.h.p., and in each steamer accommodation will be provided for about sixteen first-class passengers. A contract for four electric launches has been secured by Messrs. T. B. Seath & Co., Rutherglen. The order was from Messrs. Morton & Williamson, Glasgow, who were acting for the Electric Traction Company in London, who will supply the electrical apparatus for propelling the launches. They are intended for service on the Seine.

ELECTRICAL TRANSMISSION.—A case of fire which is alleged to have been due to defective insulation, and consequent short-circuiting through a gas pipe, has just occurred in Glasgow. An inquiry is being made into the matter, on behalf of the engineers, by Sir William Thomson. It is premature to ascribe the fire to electricity until this inquiry is completed.

PIG IRON.—This has been the quietest week that we have had in the pig iron market for some months past. Selling out by outsiders has still been the principal feature, but all their iron was daily absorbed by a good number of buyers, whose principal ground of confidence seems to be the increased cost of production and scarcity of material. The large deliveries ex store, fully 9,000 tons per week, contribute also to impart steadiness to the trade. The agitation in England for an increase of wages threatened at one time to interfere seriously with the production in Cleveland and Cumberland, but the fear of this has passed away in the meantime.

(From our own Correspondents.)

LIVERPOOL, 5TH MARCH, 1890.

THE DOCK STRIKES.—The strike amongst the dock labourers is now assuming large proportions, and although there were only about 150 men out at the North End on Monday, there are now nearly 5,000 men affected, and the numbers are increasing daily. The Dock Labourers' Union are extensively placarding the dock walls recommending the men to strike, and are offering the men 13s. per week strike money. The shipowners have offered to pay the labourers 5s. instead of 4s. 6d. per day; for breaking out screwed cotton, 6s. instead of 5s. and 5s. 6d.; and stevedores will be paid 7s., foremen and boys to be paid according to agreement. The men, however, have refused these terms. A large number of men are being imported from other towns, and at present no serious delays have been occasioned by the strike.

SHIPPING AND EMIGRATION.—Dr. J. Stopford Taylor, the medical officer of health, has just issued his annual report, in which he states that the total number of vessels which entered the port last year was 23,475, of which 22,227 were British; of these vessels 5,528 were engaged in the foreign trade, and 17,947 in the coasting trade. The great increase in the number of coasting vessels may be partly accounted for by the number of wooden coasters employed by the subcontractors of the Ship Canal. The number of emigrants which passed through Liverpool last year was 197,855, showing a considerable decrease on the number of the year before, when 240,566 passed through, being the largest number recorded for many years.

LIVE STOCK AND DEAD MEAT IMPORTS.—Ten steamers arrived in the port last week, with 1,956 cattle and 12,745 quarters of beef, showing a decrease of 514 cattle and 5,032 quarters of beef from the imports of the previous week.

Digitized by Google

SHEFFIELD, 5th March, 1890.

The Coal Trade.—The threatened strike is the talk of the hour. A stoppage of the coal supplies would prove a most serious matter in all branches of industry. Colliery owners are beginning to stock coal in earnest, so as to be ready for any emergency. The great iron and steel firms who have collieries of their own are not in such a serious position. Messrs. John Brown & Co., Limited, of the Atlas Works, are reported to have bought outside 12,000 tons of of coal. Their three blast furnaces will, however, soon make short work of this. Messrs. Cammell are endeavouring to lay in a stock of fuel with a view to contingencies. Altogether matters are assuming a serious aspect.

Iron and Steel.—A much quieter tone has prevailed here during the past week, and there is a decided tendency towards a lowering in values all round. The demand for railway materials shows no abatement. Most of the home railways are in the market for rolling stock, and there is also a large amount of work in hand for English Colonial railways. The Cape has been an excellent customer. Indian States also have done well in this respect.

Traction of Heavy Castings.—The question of moving heavy masses of iron and steel is becoming of great importance here. It is not at all uncommon to see twenty-four horses attached to a heavy lurry carrying a casting or forging of 40 or 50 tons. A few broad-wheeled traction engines, by Fowler, of Leeds, have been introduced with excellent results, and, as most of the streets are laid with concrete foundations, very little damage is done to them.

NORTH STAFFORDSHIRE, 5th March, 1890.

The Iron Trade.—There is no disguising the fact that in sympathy with the northern markets there is a material falling off in the revival of trade. Demand is decidedly flat, inquiries for new work are scarce, and orders are being withheld. The consequence is that makers are making concessions from the best prices which have ruled. The forges and mills are still working full time, but order books are not in such a condition as to inspire confidence with regard to the immediate future. Pig iron is only being bought to cover immediate requirements, and it seems likely that consumers will soon be in a position to force makers to lower figures. The agitation amongst the miners for a further advance in wages causes another complication in the industrial situation.

The North Staffordshire Mining Institute.—The annual meeting of this Institute was held last week, when the president, Mr. James Heath, delivered an interesting address, dealing with the work of the Institute and general mining topics. The occasion was utilised to present Mr. T. Wynne, the late Government Inspector of Mines for the district, with a purse of £100. Mr. Sawyer, the assistant Government Inspector, announced his resignation of that office, he having decided to migrate to the Witwatersrand goldfields, which he visited last year.

LEICESTER, 5th March, 1890.

Wool Spinning and Yarn Trade.—The local wool market is in a very undecided condition, though there is not much change. There are indications from some quarters of a tendency to take less prices. The market is quiet, as many users have filled up their stocks at the late London sales, and they are inclined generally to hold out for a small concession. Skin wools are most in demand. Spinners are all fairly well employed, and have orders on hand to keep their machinery fully employed for some time. Though a good deal of new business is on offer, spinners are not eager and hold for a little advance.

Boot and Shoe Trade.—The large turnover now being made is much above the average for very many years. Orders continue to come to hand, and these new orders, with those already on the books, are causing a difficulty in meeting the demand. All the houses are in full work, and the workpeople are not sufficient to cope with the requirements of buyers. Some authorities are inclined to look on the present activity as a "boom," and hint at overbuying; but the majority of the trade think that the business is sound, and that there is every probability of its continuance for some time to come. At any rate the present condition of business is eminently satisfactory for both employers and employed.

SWANSEA, 5th March, 1890.

Tinplates.—There is no noticeable alteration in the market value of tinplates, and although further stoppages are reported, making the total of idle mills to exceed sixty, it is announced that eight new mills are to be laid down at Pentyrch. In regard to the much-talked-of general stoppage during the week commencing the 10th inst., it is computed that, if taken up with complete unanimity, stocks would be reduced from their present figure of 500,000 boxes down to 250,000, a result that could only have a beneficial effect on prices. As Llanelly, however, almost entirely depends on the tinplate trade, the proposal is not taken up in that place with the enthusiasm that would augur success for the movement. Several works—notably the South Wales, Messrs. Moorewood & Co., and the Western—hold aloof from the combination, as their stocks are depleted and they are bound to complete certain contracts. It is feared, therefore, that on this, as on previous occasions, concerted action of the whole trade is impossible.

Gas Companies.—The Cardiff Gas Company, at their 106th half-yearly meeting recently held, declared a dividend at the rate of 10 per cent. per annum on the "A" shares. The directors are considering the offer of the Corporation to take over the works at a twenty-seven years' purchase upon the maximum dividend paid by the company during 1889, amounting to £16,450. The company propose to keep the reserve fund, which amounts to £15,403, for compensations, &c., and that the Corporation shall pay the amount now owing upon capital account, namely, £44,337. The offer is generally looked upon with such favour that the stock has increased in value 20 per cent.—The Carmarthen Gas Company show a decline of 800,806ft. in their sales of gas during 1889 when compared with those of the previous year, but are still able to declare a dividend at the rate of 7½ per cent.

Extensions at Cyfartha.—A fourth blast furnace and three additional stoves are now in rapid progress at these works, which it is intended shortly to bring into vigorous operation.

Briton Ferry Chemical Company.—This company, which only three years ago was started with a capital of £25,000, has already paid in dividends to its shareholders £14,300, or considerably over 50 per cent. on the capital. Mr. E. A. Pontifex, chairman of the company, stated at the recent meeting that the directors look for a considerable increase of profit in the future from sulphate of copper, owing to its great demand to resist the ravages of the phylloxera.

CARDIFF, 5th March, 1890.

Coal and Coke.—The steam coal business still exhibits a healthy appearance, and, as the demand is considerable, prices show no sign of weakness. In fact, colliery proprietors are so well contracted over the year that there is every prospect of prices being maintained, at any rate for the next six months. Merchants are taking the opportunity of shipping all the coal they can to their customers and coaling depôts abroad while the freights keep low. A large amount of coal which formerly came to Cardiff Docks is now being diverted to Barry, but as business is so brisk the docks at Cardiff do not seem to be appreciably affected; it is when times become depressed that the strain will come, as the Barry authorities, who are all large colliery owners, will certainly support their dock and railway in preference to Cardiff. Meanwhile the trustees of the Marquis of Bute are offering facilities for the development of an import and factory business, for which Cardiff is admirably well placed. The price of small coal continues high and house coal is difficult to obtain. The coke trade is quiet as far as new business is concerned, but coke makers have more than they can do to execute deliveries under existing contracts.

Iron and Steel.—The rail trade is a little less active, and lower prices for single parcels have been accepted. Makers, however, are firm in their quotations for forward delivery. Tin bars are firm. In pig iron only a limited business has been done, and that principally by merchants who have bought from works, who are bound to take delivery.

Iron Ore.—The iron ore market is firm, but no business of importance has been reported. Rubio is quoted at 16s. 6d. to 16s. 9d. c.i.f. Cardiff and Newport. Freights from the ore ports are steady.

BARROW-IN-FURNESS, 5th March, 1890.

Restriction of Output of Pig Iron.—A policy for restricting the output of hematite pig iron is still being urged on the attention of makers of pig iron, and a meeting is to take place shortly with a view to carrying into effect this difficult problem if at all possible. In the meantime makers are doing no business, but are busy on old orders, and have work in hand for about three months. Although the cost of producing iron is put down at 76s. per ton makers are quoting as low as 72s. Hematite warrants are changing hands at 64s. 6d. per ton. The market shows no signs of increased firmness.

The Steel Trade.—There is great industrial activity in every department of the steel trade, but the orders coming to hand are very few in number. Buyers are waiting for lower prices, and makers are not ready to concede these at present. The ruling quotation for heavy rails is £6 12s. 6d. per ton, but no business has been done at this figure. Shipbuilding steel is in quieter demand, but makers are busy on old orders.

The Tinplate Trade.—Many of the tinplate mills have suspended operations owing to the inability of making a profit. The consequence is that an important branch of the local steel trade will soon be without orders.

Stocks and Shipments.—After three weeks' successive reductions in the stocks of hematite warrants, a further decrease is reported this week to the extent of 893 tons, the stocks at present representing 380,437 tons, or 1,210 tons less than at the beginning of the year. Shipments continue to show an increase. This week they have represented 22,152 tons, compared with 18,667 tons in the corresponding week of last year, an increase of 3,485 tons. The shipments from the beginning of the year, however, show a decrease of 11,955 tons as compared with 1889, but spring shipments are expected to be on a large scale.

MIDDLESBROUGH, 5th March, 1890.

Pig Iron.—The market held yesterday was very flat. There were few present, and very little business was done. Buyers are waiting to see which way the market will turn. Makers are firm, and will not sell lower than 60s. for No. 3 G.M.B. prompt. Those who require iron prefer warrants, which have dropped to 51s. 7½d. cash. There is little desire shown to buy forward at present. In hematite mixed numbers of makers' iron are quoted at 78s. per ton East Coast brands, but in warrants they can be had at 63s. 10d. The stock in Connal's store on Monday, the 3rd inst., was 1,768,666 tons, against 179,786 tons on the previous Monday, being a decrease of 2,920 tons.

Shipments of Pig Iron.—The shipments abroad are rather more than they were at this time last year, but those coastwise are just about half. The total for the month of February amounted to 41,967 tons, against 57,426 tons for the month of February last year.

Ironmasters' Returns.—The total make of pig iron of all kinds for February amounted to 221,517 tons, against 236,327 tons for January, showing a decrease in the make of 14,810 tons. There were three more furnaces blowing, but there were three days fewer in the month. At the end of January the total stocks amounted to 271,892 tons, and at the end of February 279,029 tons, showing an increase of 7,137 tons.

Manufactured Iron and Steel.—Manufactured iron and steel are very quiet at present. There are no new orders and very few inquiries, and prices are inclined to droop. Iron ship plates are at £7 10s.; ship angles, £7 5s.; bars, £7 10s.; steel ship plates, £8 10s.; ship angles, £8 5s.; sleepers, £7 10s.; rails (heavy section), £6 12s. 6d. per ton, less 2½ per cent. on trucks at manufacturers' works.

Coal and Coke.—These commodities have been easier since the acceptance of the 5 per cent. by the miners. Manufacturing sorts are at from 9s. 6d. to 13s. per ton delivered at works; and households range from 14s. to 17s. according to quality. Coke is quoted at from 26s. to 28s. delivered here.

NEWCASTLE, 5th March, 1890.

The Dispute in the Engineering Trade.—The operative engineers have rejected the offer made by the employers of an additional 6d. per week in lieu of the curtailment of the working time by one hour on the Saturdays, and have given notice to discontinue working on the 8th, unless the last-named demand is complied with. The situation has consequently become very critical, as a strike is certain to ensue if the employers remain firm in their determination to resist any reduction of the present working hours. A meeting of the employers will probably be held in Newcastle some day this week, to consider what action, if any, can be taken by them under the circumstances, and it is possible that as the outcome of that meeting a proposal may be made involving such a rearrangement of the working hours as will—without reducing them—practically give to the men the privilege of ceasing work at noon on Saturdays. Such a proposal if made to reasonable men would almost certainly lead to a settlement, but it is to be feared that the engineers, in their present temper, will refuse to listen to any proposal which involves the acceptance of anything less than their full claim. Should a strike take place several thousands of men will be directly affected in the Tyne district, and its continuance will very soon bring enforced idleness to a much larger number.

The Coal Trade.—The acceptance by the Durham miners of the 5 per cent. advance offered by the coalowners in response to a demand for 15 per cent. has caused a good deal of satisfaction in commercial circles, and greatly helped to dissipate the feeling of uncertainty which, while it existed, was seriously hampering trade. As the announcement of the miners' decision only became generally known on Monday the effect of the better feeling established is scarcely yet felt in the market, but no doubt is entertained that business will undergo improvement shortly.

New Ordnance Works.—The announcement has just been made that the Palmer's Shipbuilding and Iron Company, Jarrow, contemplate the immediate addition to their extensive works of a department for the manufacture of ordnance and its accessories, including gun-carriages. Colonel English, R.E., who is at present engaged at the Woolwich Arsenal, is to superintend and direct the department, which, when thoroughly under way, is expected to constitute one of the most important and interesting features of the company's great establishment. The number of men at present employed by the Palmer's Company, including those at the Howdon shipyard, is about 7,000, and it is expected that the new enterprise will give employment to 1,500 more. It is understood that for the purposes of the undertaking new capital will be called for immediately, and that the erection of the necessary buildings will be commenced without delay.

Chemicals.—Alkali makers here are feeling very severely the increased cost of manufacturing consequent on the high value of coals, and unless prices of soda products improve presently, there must inevitably be a restriction in the output. The gentlemen engaged in the formation of an Alkali Union have lately visited this neighbourhood, and have interviewed the various alkali manufacturers. The scheme has met with much favour here. Stocks of soda are large, as is commonly the case at this time of year, amounting to a little over 4,000 tons.

MESSRS. ARBEY'S TOOLS AT THE LATE PARIS EXHIBITION.

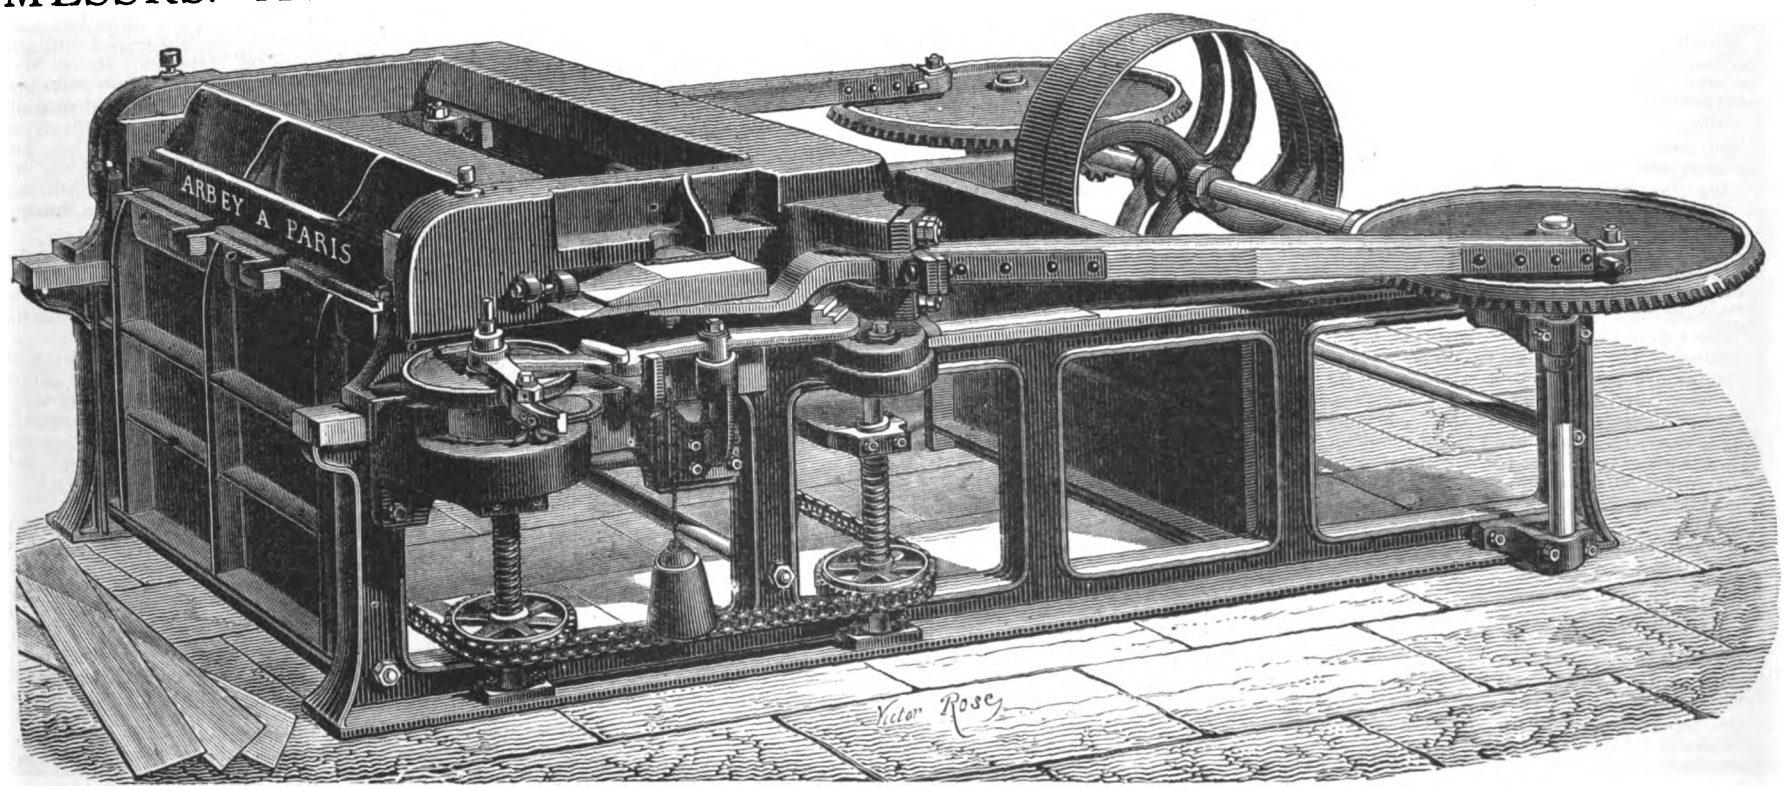

FIG. 1.—GENERAL VIEW OF VENEER CUTTING MACHINE

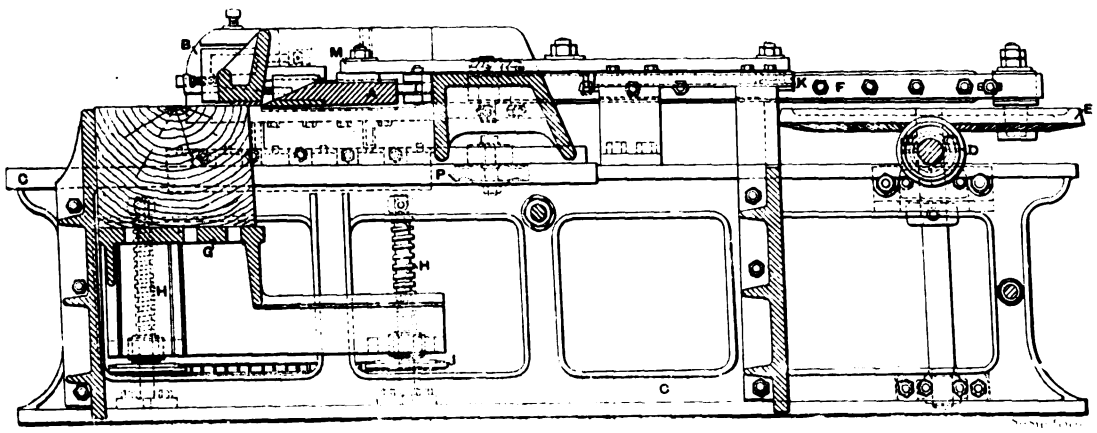

FIG. 2.—SECTIONAL ELEVATION.

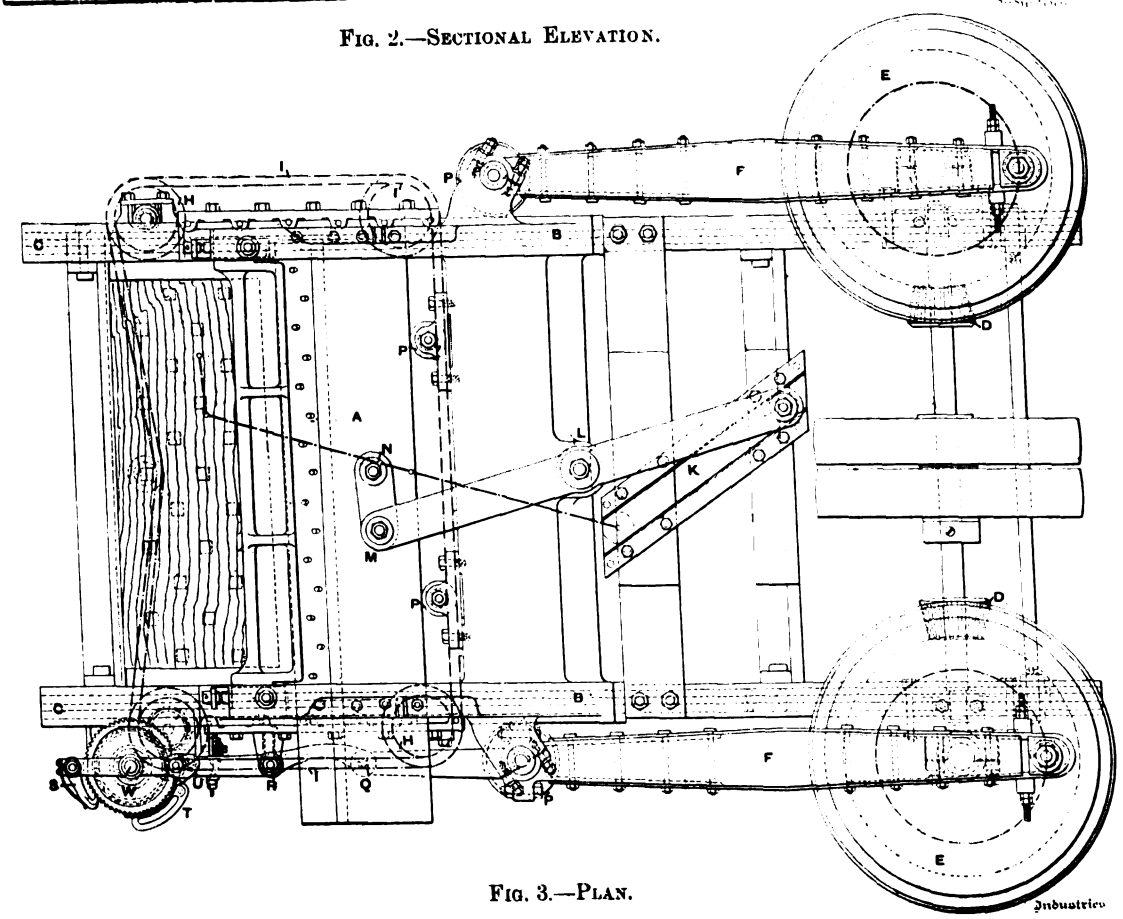

FIG. 3.—PLAN.

MESSRS. ARBEY'S TOOLS AT THE LATE PARIS EXHIBITION.

III.

A VENEER cutting machine exhibited by Messrs. Arbey is shown in Figs. 1, 2, and 3 herewith. Fig. 1 shows the general arrangement of the machine, Fig. 2 is a section through the middle of the machine taken longitudinally, and Fig. 3 is a plan. The wood to be cut into veneers is fastened on to the table G, which is raised and lowered by means of four screws H. The knife A is supported by the carriage B, which slides backwards and forwards over the wood to be cut, supported by slides on the top of the bed C. As the knife advances over the wood a lateral motion is given to it in addition to its forward movement. We shall first describe the mechanism for moving the knife. On the driving shaft are two bevel pinions D which work into two inverted bevel wheels E. Pins attached to the wheels E connect them with the carriage B by means of the connecting rods F. One of these being fastened to each side of the carriage B, a very steady motion is obtained. Wheels P attached to the carriage B, and running against vertical surfaces on the bed C, give additional steadiness to the carriage without increasing the friction. The traversing motion of the knife is obtained as follows: Guides K are fixed to the bed of the machine, a lever M K has its fulcrum L on the carriage B. The end K is compelled to move along the groove K K, the end M being connected with the knife A by means of the link M N. Thus as the groove K is traversed by one end of the lever the knife is compelled to oscillate across the carriage. The feed motion for the table is obtained by prolonging the connecting rod F to Q. A pin at Q moves one end of the lever U R Q. The end U of this lever vibrates the ratchet S, to which it is connected by the lever S U through a short connecting link. The ratchet wheel W turns one of the screws H by means of gearing, and this causes the table to rise or fall as required. The feed may be varied by sliding a stop T over the teeth of the ratchet wheel, thus causing the ratchet to take only one, two, or more teeth as they may be exposed. Chain wheels fastened to each of the screws H, and connected by a chain I, compel all the screws to move together, and thus the table is kept horizontal. The advantage of cutting veneers in this machine instead of sawing it is that no material is wasted and no sawdust is produced. The first of these machines was made by this firm in 1835, and since then it has been gradually developed until it has reached the state of perfection shown by the machine now illustrated, which produces a beautiful veneer, very fine and with a good surface. The machine shown will make veneers up to 1 metre long, 0·35m. wide, and up to 6mm. in thickness.

Advertisements intended for insertion in the current week's issue should reach our London Offices not later than first mail delivery on Thursday morning. Scale of charges for displayed advertisements on cover and inside pages will be forwarded on application. Orders for single advertisements must be accompanied by payment in order to insure insertion, the charge for which is 2s. 6d. for the first four lines or under, and 8d. for each additional line. Situation advertisements (Vacant or Wanted) 1s. for two lines or under, and 6d. for each additional line—which averages eight words. While all practical regularity in the insertion of serial advertisements will be observed, it can only be absolutely guaranteed in the case of those ordered to appear weekly.

As we go to press early with certain of our advertisement pages, all Alterations to Standing Advertisements should reach the Publisher not later than 2 o'clock on Wednesday afternoon in each week.

All accounts are payable to GEO. CAWLEY, *358, Strand, London, W.C. Cheques should be crossed Manchester and Liverpool District Banking Co., Limited, 75, Cornhill, London, E.C. Post Office Orders should be made payable at the Post Office, 369, Strand, London, W.C.*

Industries:

FRIDAY, 7TH MARCH, 1890.

THE DEVELOPMENT OF THE STEAM ENGINE.

IN a recent issue (see *Industries*, Vol. VIII., page 16) we shortly reviewed Professor Thurston's sketch of the development of the philosophy of the steam engine, in which he gave an account of the most important steps in the progress of the steam engine and of the principles which underlie that progress. In the concluding sentence of his paper, as read before the British Association, he expressed the opinion that the further development depended largely on the results of experiments on the lines of transfer of heat between metal and vapour, and in a postscript he indicated the results of some of the most recent experiments. From these, he said, it was now possible to construct a theory of heat-engines which may serve as a guide in design and in construction, and as a check upon the experimental determinations of efficiency made at test trials. It was further possible to predict, on theoretical grounds, the performance of any well-constructed steam engine, and to base upon preliminary computations a very approximate estimate of the probable consumption of steam, heat, and fuel of any steam apparatus which it may be proposed to design. It was also practicable to make intelligent and useful estimates of the relative value of alternative plans of construction of proposed new types of engines, and of probable actual costs of operation and of efficiencies for any given type, size, and design of engine. Although, however, the theory of the compound engine was now sufficiently well understood for most practical purposes, Professor Thurston of course recognised that it had not taken its final and complete, and its most perfect and practically available form; and he was of opinion that its final shape would probably be given by some such master of mathematical and physical science as was Rankine or Clausius. It is, of course, difficult to speak definitely about finality, but we would expect the most useful developments to come from men who have followed the works of Rankine, Clausius, and the other mathematicians, and who at the same time have had the advantage of good practical experience. Some of our younger men, if they could only free themselves from the bonds of conventional methods, or from following too closely the examples of their teachers, might be expected to lead the way. It must be confessed, however, that our present methods of education seem to lead to a decay of originality.

Professor Thurston may in a sense be looked upon as a pupil of Rankine and of Clausius, for, although he has not had the advantage of their personal influence, he has carefully studied their works, and his methods of thought and action have been largely moulded by them. We do not wish it to be inferred that he is wanting in originality, for his writings show that he has a considerable share of that valuable quality, and he is one of the most industrious workers in the field of steam engineering. His latest contribution to the department is a paper on the philosophy of the multi-cylinder or compound engine, its theory, and its limitations, which was presented at the twentieth meeting of the American Society of Mechanical Engineers, held in New York, November, 1889, and which has been reprinted from the Journal of the Franklin Institute for private circulation. It may be looked upon as a supplement to the book or paper we recently reviewed, and it brings the matter, not only up to date, but also indulges in speculations as to future developments. To make the paper complete he gives a short *résumé* of previous investigations, and enumerates the different causes of wastes in steam engines. These are: (1) External wastes, brought about by the conducting and radiating properties of the materials of construction; (2) internal wastes consisting of two parts—(a) the thermodynamic, unavoidable losses of heat rejected at the lower limit of temperature of working fluid, (b) wastes by internal conduction and storage of heat followed by later rejection with the exhaust steam; (3) wastes of mechanical energy. The unavoidable thermodynamic waste is rarely less than 75 or 80 per cent. as compared with an ideally perfect engine, and the internal wastes by conduction and storage with subsequent rejection by cylinder or internal condensation, and by leakage, range from 10 to 30 per cent. It is this which constitutes, ordinarily, the great source of loss and efficiency of the real, as distinguished from the ideal, engine. The wastes of mechanical energy through the inefficiency of the mechanism are seldom large in engines of good construction, as compared with the magnitudes, at least, of the other kinds, and may in some cases, by careful design, good construction, and skilful management, be brought down to less than 5 per cent. in non-condensing, and to perhaps 10 per cent. of the total energy in condensing engines of simple forms and high mean working pressures.

The most important developments of the steam engine since Watt's time have therefore been for the purpose of reducing the internal wastes, and these may be classified under three categories: (1) superheating; (2) steam jacketing; and (3) compounding. Attention has been largely diverted from the first since high pressure steam became so common, but we are of opinion that, with the improved materials and methods of construction, a considerable amount of superheating might now be introduced with advantage. As the greatest part of the waste arises from the action of the condensed steam, the simplest method of preventing it seems to be to raise its temperature if possible to such an extent as to leave it at the end of the expansion practically dry. If engineers would only direct their attention to the still further improvement of materials, we believe that a great advance is possible. Steam jacketing is another and common partial remedy for internal waste, and may be used in conjunction with "compounding," or in single engines, but it must never be forgotten that the steam jacket is a sort of necessary evil, justified only by the physical properties of the steam and of the materials hitherto used in construction, for, while it increases the work done by the expanding steam, the increase is by no means so great as it would be if the heat employed in the steam jacket had been applied to generate more steam for use in the cylinder. Hence in multiple expansion engines, in which the variation of temperature is not very great, steam jackets have either been wholly or partially omitted. "Compounding," or the use of the multi-cylinder engine, in which the steam exhausted from one cylinder is again worked up in a succeeding one, is the most familiar of devices for extending the economical range of expansion and increasing the efficiency of the engine, and it is to the past and future of this that Professor Thurston's paper is chiefly devoted. He states that common experience with the best constructions, which confirms theoretical con-

Digitized by Google

siderations, shows that the engineer may reasonably expect, by good design, construction, and management, to secure an expenditure of steam per horse-power per hour, at the best ratios of expansion r in really good engines, as follows:—

r	3	4	5	6	7	8	10	12	15	20	25
Lbs. per i.h.p. per hour	32	27	25	22	20	20	19	17	16	15	15

and in peculiarly favourable cases 10 per cent. better figures than these have been actually reported. The practical question which faces the engineer is how far expansion is to be taken advantage of, for it is soon found that useful expansion has its limits. Our space will not allow us to enter into the details of Professor Thurston's reasoning, although we may return to it on some other occasion. We can only in the meantime give some of his results. The extent to which expansion may be economically carried in a simple cylinder will vary somewhat with the initial temperature and pressure, and with the physical condition of the working fluid; but it may be taken as ordinarily not less than $2\frac{1}{2}$ expansions for unjacketed engines with wet steam, and 3 or 4 for the better class of engines, and the total expansion ratio for the several types of multi-cylinder engines is given in the following table:—

No. cylinders	1	2	3	4
r	2·5 to 3	6·25 to 9	16 to 27	40 to 81
Init Pres. ...	25–30lb.	60–100lb.	120–300lb.	350–800lb.

expansion being assumed to be approximately hyperbolic and the terminal pressure to be 8lb. or 10lb. per square inch. High engine speed is the most modern device for reducing internal wastes, as well as of decreasing costs of engine construction, and to a certain extent it reduces the necessity for the other expedients for preventing waste, but all are to be adopted when high efficiency is desired.

Professor Thurston enters at considerable length into the question of the relative efficiency of the single engine and of the various classes of the multi-cylinder engine. His results are both interesting and instructive, as he even goes the length of considering the case of a quintuple expansion engine, working with an initial pressure of 500lb. on the square inch. He further considers the questions of commercial efficiency and proportions of cylinders, which we may also notice on some future occasion, and in the meantime we commend his paper to the careful consideration of our engineering readers.

THE COMPULSORY LOAD LINE BILL.

The Bill which is now before Parliament, for the purpose of amending the Merchant Shipping Acts relating to a load line, is one which commends itself to those who have really studied the question, and who are not biassed by selfish considerations, and we think that public opinion has now been sufficiently educated on the subject to allow us to ask that every endeavour should be used to get it passed during the present session. It has been introduced by Mr. Broadhurst, and is backed by Sir W. Harcourt, Mr. Burt, Mr. Howell, Mr. Staveley Hill, Mr. C. Wilson, Mr. Heneage, and Sir Edward Reed, and, moreover, has received the support of a large number of members of Parliament of all parties. The Bill is very short, consisting only of three clauses, and its main provision is the substitution in the twenty-sixth and twenty-seventh sections, of the following subsection, instead of the subsections numbered (2) in these sections respectively:—The centre of this disc shall be placed at such a level below the deck line marked under the provisions of this Act as may be approved by the Board of Trade from time to time, and shall indicate the maximum load line in salt water to which it shall be lawful to load the ship, until the position of the disc is altered by direction of the Board of Trade. The Bill further provides that the Board of Trade may from time to time appoint any of their surveyors or officers of any corporation or association for the survey or registry of shipping, to approve on their behalf from time to time the position of any such disc as aforesaid, and any alteration thereof, and may appoint fees to be taken in respect of any such approval.

When the Bill was first introduced it was thought that considerable opposition would be offered by the shipowners, but we are informed that the promoters have agreed to amend it so that Lloyd's Register Committee should be the agents to carry out the marking of the compulsory load line, and that opposition has been withdrawn. Lloyd's Committee is now, or about to be, made more representative of all interests than it has hitherto been, and we suppose that the shipowners think that it will be more amenable to reason than an irresponsible Government official, or even a Government Department, which very often means the same thing. We further understand that Sir Michael Hicks-Beach will give the measure official support. We trust, therefore, that no unreasonable opposition may be offered to the measure which will prevent it being carried into law at once. There can be no doubt, however, that in some of its bearings the matter will require to be very delicately handled, and care must especially be taken that we do not unnecessarily handicap our shipowners, and drive some of them to take refuge under a foreign flag. It seems only reasonable to insist on foreign ships being subject to the same regulations as our own when they are in our ports, and in connection with this it is worthy of note that at the recent meeting of the International Maritime Conference in Washington it was decided that the time was not yet ripe for the discussion of the question of a maximum load line. We do not know the grounds for this decision, but we cannot agree with it, and we cannot see any reasons why there should be any difficulty in arriving at an international understanding on the subject. We can at least insist on foreign vessels being subject to the same regulations as our own when they are in our ports, and, as Mr. Charles Wilson, of Hull, has said: "No consideration of what foreigners can do can justify English shipowners in loading their ships beyond what is ascertained to be their maximum capacity." A reduction in trade profits cannot be put forward as a reason against passing a measure which is needed to save life.

It is now more than fifteen years since the agitation on this subject was commenced by Mr. Plimsoll, and during that period public opinion has been ripening, and some measures have been passed which have effected a considerable improvement in the position of seamen. In 1880 the question of a compulsory load line was referred by the Government of the day to a Committee, and a Bill was introduced into Parliament by Mr. Chamberlain for the purpose of carrying out the decisions of that Committee. Some of these were rather harsh, and a considerable amount of bad feeling was displayed by both sides, and the Bill, being vehemently opposed, was withdrawn. This led to the appointment of a Commission in 1884, to ascertain the true facts of the case. Their report was about as authoritative as it was possible to obtain, and they had no difficulty in giving definite instructions about the load line. They made out tables for different classes of ships, which have been largely adopted by shipowners, and the result has been a considerable reduction in the number of disasters in consequence of overloading. But in every trade or profession there are some "black sheep," and without legal compulsion they would follow their own selfish ways. At present the load line is put on the ships by the owners themselves; in some cases they are too high, and in a few, Sir William Harcourt said, in introducing a deputation to the Board of Trade, they were put on the funnel. This of course was an exaggeration, for the law at present required the line to be put on the side of the ship, and a severe penalty was imposed on those who did not comply with the regulation. As, however, no definite authority exists for fixing the position of the line, it might in some cases be on the funnel for any good it does, for notwithstanding the improvement which has taken place there is still a considerable number of vessels lost every year through overloading. Mr. Plimsoll has collected statistics of these, but we need not at present enter into details.

As to the practicability of fixing a fair load line the report of the Commission leaves no doubt, as the members were unanimous in saying that they were of opinion that it is now practicable to frame general rules concerning freeboard, which will prevent dangerous overloading without unduly interfering with trade. Speaking of the scales of freeboard which they recommend, they say: "It will be observed by the tables that they refer exclusively to cargo-carrying vessels, but it must be understood that, under any circumstances, these tables contain the maximum loading that should be permitted to any class of vessels."

The points requiring most careful consideration are, first, the authority by whom the load line shall be fixed, for we can imagine that some shipowners, whose ships are not on Lloyd's Register, may object to Lloyd's Committee being named for that purpose, and may insist on an independent and representative body; and second, how foreign ships are to be affected by the legislation when in our ports. We think there need be no great difficulty over either of those points. A special representative committee might be appointed which would represent all parties, an arrangement which would settle the first point. As to the second, we have no hesitation in saying that foreign vessels when in our ports should be subject to all British regulations. In those days of international conferences we think that this is a matter about which an international agreement might be come to, and we fail to see any serious difficulties in the way, except those arising from wrong motives, and these could easily be overcome. We are glad to see that the questions are being taken up by men of all political parties, and we trust that they will be considered in a common sense business manner, and useful and definite conclusions arrived at as soon as possible.

THE LATE SIR EDWARD BAINES.

By the death of Sir Edward Baines, which took place at his residence, near Leeds, on the 2nd inst., Leeds has lost a well-known citizen. Born in the first year of the century he had thus reached his ninetieth year, and for seventy of these at least he might be looked upon as a working journalist. At his death he was the principal proprietor of the *Leeds Mercury*, with which his connection dates back to the year 1815, when he was fifteen years of age. Although journalism was his profession, and while he did all he could to advance the interests and improve the status of his paper, he by no means confined himself to the work connected with it, but took an active part in many social and political reforms, and especially in those connected with temperance and education. Over half a century ago he founded the Yorkshire Union of Mechanics' Institutes, of which he was president from its foundation. The Union has done most important work in its day by co-ordinating a large number of institutions, and thus economising work and money, and also in bringing together men engaged in the work of the education of artisans. It now includes nearly 300 institutes, with about 14,000 students in their various classes, the greater number of whom are studying technical subjects. In 1835 he published his "History of the Cotton Manufacture in Great Britain," which even yet is looked upon as the standard work on the subject, showing, as it did, extensive reading and research, and a considerable knowledge of mechanical details. When the Yorkshire College was founded he was one of its best friends, and became Chairman of its Council. In 1880, when his fellow townsmen showed their appreciation of his services, they raised a memorial fund, which, in accordance with his desire, was applied partly towards the erection of a wing of the Yorkshire College, and partly towards the creation of scholarships at that institution.

Sir Edward represented Leeds in Parliament from 1859 to 1874, and during that time he brought in many measures and took a very active part in various commissions of inquiry. In 1880 he received the honour of Knighthood.

SIR WILLIAM ARROL ON LABOUR QUESTIONS.

On the 26th ult. Mr. (now Sir) William Arrol was presented with the freedom of the town of Ayr, in recognition of his conspicuous skill and notable achievements as an engineer. This was a considerable honour, for it has been very sparingly given heretofore, and only to very distinguished men. Sir William, no doubt, finds such recognitions of his skill and ability as an engineer and his worth as a man highly gratifying, but we feel they are now to a certain extent superfluous. The "twa brigs" which Sir William spoke about are the best monuments he can have, and they will endure long after the memory of town council or even greater ceremonies of a like character have passed away.

To those who study the industrial questions of the day the ceremony at Ayr was interesting chiefly on account of what Sir William said on questions connected with labour. He is beginning to feel, what has been felt by our most distinguished engineers, that it is much easier to engineer matter than men and industrial conditions. We do not mean that he has had any difficulties with the men directly under his control, but rather with the more general conditions affecting labour and materials. He said he spoke as a representative of the working classes who had been able to raise themselves by their own energy and industry, and, therefore, he could do it with greater freedom than if he had only been a capitalist. He was afraid the working classes at the present moment had "got the bit in their mouth, and were going to run away with it." He said he had seen a few gentlemen that day, employers of labour, and they were all complaining about the prospects of the coming year. He was afraid that the working men would soon run away with the great prospects of the past year, and that at the end of the year we would be at a dead standstill. This he attributed to the present state of trades unions and stock exchanges. Trade could not get settled down to the same quiet

Digitized by Google

steady pace they had a number of years ago. No person was safe to go in for any contracts that would last over two years. He knew that for his part he had been offered, within the past twelve months, work to the extent of more than a million of money, and he could not look at it in the present state of the labour and money markets. There was no safety in anybody going outside their own country. Things were no sooner settled than the whole of the trades unions were down upon employers, and raised the wages to such an extent that work could not pay.

Sir William also touched on the subject of the education of artisans, and said he was sorry that they were not profiting as much as they ought to by the opportunities which were now offered. Too many youths were aspiring to be clerks, or to get some other light employment, instead of learning a trade, and the result was that the country was being overstocked with that class, and it was found very difficult to get steady trustworthy tradesmen. If they advertised for a tradesman they would not get a single application; if they advertised for a clerk they would get more than 500. He thought that was a point that our legislation should take up, and instead of advocating an eight hours day induce more men to learn a trade. Many thousands of clerks and warehousemen never knew the advantage of an improvement in trade. It was only the few who, for instance, felt the advantage in the coal trade, and the same was true of other departments. Things were getting into so few hands that every year matters were becoming worse, and the only remedy was for a great many of our young men to learn trades, so as to enable them to get a share of the general prosperity and to keep things going as they used to. Sir William's remarks have such a direct bearing on the opinions we have often expressed on education, that we mention them for the purpose of showing the necessity for what is usually called "technical education" being placed on as wide a basis as possible, so that those who partake of it may see that by taking too selfish a view of matters they are not only injuring the community, but also themselves.

Letters to the Editor.

"RACK-RENTED TRADESMEN" AND THEIR CUSTOMERS.

To the Editor of "Industries."

Sir,—Permit me, on behalf of the "Tenant Tradesmen's Union" throughout England, to thank you very heartily for your generous advocacy of this important national movement—important to every family in the United Kingdom, who, however great or small their weekly purchases may be, unitedly pay many million pounds a year to meet the arbitrary and unjust exactions of the landlords of shop property. The Tenant Tradesmen's National Union is making solid progress. The question is being rapidly understood by all classes of society. Up to date the honest enterprising tradesman, who creates a business, finds himself, at the end of a short lease or agreement, fined by his landlord for that very business energy which has secured to the landlord payment of the rent and due care of the premises. The fines have been monstrous in many cases. Double or treble rent, heavy premium, rebuilding of premises—one or all of these ruinous conditions have been imposed by landlord or agent on the man who has alone made the goodwill of the business, and is alone honestly entitled to the beneficial result of his labour, capital, and skill. The owners of private house property cannot, dare not, attempt such pillage. It should be remembered, too, that while these extortions harass, impoverish, and, in thousands of cases annually, ruin the tenant tradesmen, the purchasing British public are the ultimate victims. From the incomes of his customers must the tradesman pay his predatory landlord. The day of reckoning for such landlords is at hand, and they know it. The Tenant Tradesmen's National Union are already prepared to promote local meetings throughout the length and breadth of England. Let shopkeepers in every part of London, and in every provincial town, signify their willingness to unite with their customers in this warfare against unjust landlords. Were united action promptly organised, within a few months local tradesmen would be able to undersell the barrack-like "stores," and their customers have the advantage of obtaining, in their immediate neighbourhood, the best articles of every description, and, in all respects, the best value for their money.

All communications addressed to me at "International College, Finchley Road, London." will receive prompt attention.

Yours, &c.,
James Haysman,
President of the Union.

London, 3rd March, 1890.

MINING MACHINERY FOR SOUTH AFRICA.

To the Editor of "Industries."

Sir,—It is somewhat surprising that none of the firms concerned in the export of mining plant have answered what is virtually a challenge in the statement of your Berlin correspondent a short time ago respecting the inferior quality of the plant sent out to South Africa. I was very dubious as to accepting his representations as correct, attributing them to the customary German theories, but since reading them I have found corroborative evidence in one of your financial contemporaries evidently derived from a totally different source.

The complaint made there is not so much in respect to inferior workmanship as to excessive weight. This is easily accounted for. Engineers in this country have always made a special point of the solidity of the machinery which they build, and have been inclined to jeer at the ricketty kind of work turned out on the Continent and in the United States. When, however, the transport of a ton weight to a gold mine in the interior of South Africa means a question of £30 this is a serious item in the cost of a plant

Our consuls have repeatedly, in various parts of the globe, drawn attention to the disregard by British manufacturers of local requirements, and this seems to be a case in point. It is evidently necessary that the standard patterns, however good in themselves, should be laid aside, and lighter apparatus constructed to suit the special requirements of the district.

I am not personally interested in any of the South African mining speculations, nor in the firms supplying the material, but I would look with regret on the departure of this branch of export business from these shores.

Yours, &c.,
S. A.

London, 4th March, 1890.

THE OPENING OF THE FORTH BRIDGE.

On Tuesday, the 4th inst., the Forth Bridge was formally opened by the Prince of Wales. The occasion was naturally made a great railway function, the directors and chief officials of the railways of the United Kingdom, and also of those of the Continent, being invited to be present. The lists of guests was a very distinguished one. There were present the directors of the railways most concerned in the success of the bridge, and a large contingent of foreign visitors, of whom M. Eiffel was perhaps the most widely known.

The Prince of Wales arrived at Dalmeny on Monday evening as the guest of Lord Rosebery. His Royal Highness was accompanied by T.R.H. the Duke of Edinburgh, Prince George of Wales, the Duke of Fife, &c. The dinner party on Monday evening included Sir John Fowler, Mr. Baker, and Mr. William Arrol. The Directors of the various railway companies and their invited guests left Edinburgh about 11 o'clock on Tuesday forenoon in two trains. On the arrival of the second of these at the Forth Bridge Railway Station the Prince of Wales and his party joined the train, travelling in a saloon carriage with glass on all sides. The train steamed slowly across the bridge, upon which there was found to be blowing a gale of considerable violence. The pathways on the bridge were open to a small number of invited guests, and though these, for the most part, did not venture beyond the arch which marks the end of the approach viaduct, their elevated situation, exposed as it was to the full force of the wind, was anything but comfortable. On the bridge itself bluejackets were stationed at intervals, and the time which elapsed between the first crossing of the Royal train and its return must have been, even for the sailors, an unusual experience of exposure. The Royal train passed on to the bridge shortly after eleven, and passed across it at a slow pace, H.M.S. "Devastation" firing a Royal salute during the passage. The train arrived at the north side in ten minutes after entering the bridge, and then proceeded at a higher rate of speed to Inverkeithing, through the tunnel and cuttings immediately to the north of the Forth. A return was then made by the old line to North Queensferry. On the arrival of the train at the old station the party walked to the pier and embarked on board two steamers, the Royal party being on board of the "Dolphin." The vessels steamed out into the Firth, passed underneath the north span, sailed round the island of Inch Garvie, and, after a voyage of about half an hour, returned to North Queensferry Pier, where the party rejoined the train, which was then shunted to the new line, from which it passed on to the bridge. It had been arranged that the ceremony should consist of two portions—one, the driving of the last rivet, was to take place in the north connecting girder in the centre of the north span, and the other, the declaration of the opening of the bridge, was to be performed at the stone arch into which the end of the south steel cantilever is fitted. This programme was carried out. A small platform, with a hydraulic riveter, which was supplied with the necessary pressure from Inch Garvie, was fitted in the centre of the connecting girder of the north span. With the aid of Mr. Arrol and Mr. Phillips, the Prince turned the valve fixed on the pressure main with a silver key. This ceremony, performed as it was in the middle of a severe blast, was witnessed by very few, the bulk of the guests preferring to remain in the comfort of the railway carriages. It was all over in about a couple of minutes, and the train proceeded to the arch at the south end of the bridge, where the Prince of Wales and a few of those more immediately concerned stepped for a minute or two from the carriages, and the engine was uncoupled, in order to allow the spectators on the west pathway of the bridge an opportunity of seeing the little that was to be seen. The Prince simply shouted, with his utmost vigour, "Ladies and gentlemen, I now declare the Forth Bridge open." With the wind whistling among the wind bracings, and ineffectually spending its fury on the top members of the bridge, more than a hundred feet above the viaduct, the bridge was opened in the middle of an appropriately severe trial. The perfectly calm security of the structure while so severe a gale was blowing must have impressed everyone who was present on this historic occasion. Immediately after this brief ceremonial the train passed to the Forth Bridge Station, where the party alighted and made their way to the model room, where luncheon was served. Mr. Matthew W. Thompson, Chairman of the Forth Bridge Railway Company, occupied the chair. The *menu* card was as artistic a piece of work as the invitation card was the opposite. It contained portraits of the three men whose names are in everyone's mouth as representing the builders of the bridge, and a list of the principal officers of the engineers' and contractors' staffs. The loyal toasts having been given by the Chairman, the Prince of Wales, in replying on behalf of himself and other members of the Royal Family, made a long speech, in which he recounted the chief features of the bridge.

In concluding his speech, the Prince of Wales announced that the Queen had been pleased to confer baronetcies upon Mr. Matthew Thompson, the Chairman of the Forth Bridge Railway Company, and Sir John Fowler, K.C.M.G.; that Her Majesty had made Mr. Benjamin Baker a Knight Commander of the Order of St. Michael and St. George, and also that Her Majesty had conferred a Knighthood upon Mr. William Arrol. The Prince of Wales also referred to the services of Mr. G. B. Wieland, the Secretary of the Forth Bridge Railway Company, especially in connection with the financial arrangements. The Chairman expressed acknowledgments for the honour conferred upon him, as also did Sir John Fowler, Sir Benjamin Baker, and Sir William Arrol. The Earl of Rosebery, Herr Mehrtens, and M. Picoll also spoke. The Prince of Wales left the luncheon room about four o'clock, and immediately afterwards the Directors and their guests returned to Edinburgh.

The following are among the interesting details with which the Prince of Wales was furnished for his speech at the luncheon on the occasion of the opening of the Forth Bridge:—The extreme length of the bridge, including the approach viaduct, is one and a fifth of a mile, and the actual length of the cantilever portion of the bridge is one mile and twenty yards. The weight of steel in it amounts to 51,000 tons, and the extreme height of the steel structure above mean water-level is over 370ft. above high-water mark, and above the bottom of the deepest foundation 452ft., while the rail-level above high water is 156½ft. Allowance has been made for contraction and expansion, and for changes of temperature, to the extent of one inch per 100ft. over the whole bridge. The wind pressure provided for is 56lb. on each square foot of area, amounting in the aggregate to about 7,700 tons of lateral pressure on the cantilever portion of the bridge. About 25 acres of surface will have to be painted with three coats of paint. About 8,000,000 of rivets have been used in the bridge, and 42 miles of bent plates used in the tubes, about the distance between Edinburgh and Glasgow. Two millions sterling have been spent on the site, in building the foundations and piers; in the erection of the superstructure; on labour in the preparation of steel, granite, masonry, timber, and concrete; on tools, cranes, drills, and other machines required as plant: while about 2½ millions have been the entire cost of the structure, of which £800,000 (nearly one-third of this amount) has been expended on plant and general charges. The works were commenced in April, 1883, and it is highly to the credit of everyone engaged in the operation that a structure so stupendous and so exceptional in its character should have been completed within seven years. The opening of the bridge must necessarily produce important results and changes in the railway service of the East Coast of Scotland, and it will above all place the valuable manufacturing and mineral producing district of Fife in immediate communication with the south side of the Firth of Forth. When the Glenfarg line, now nearly completed, is opened for traffic, the distance between Edinburgh and Perth will be reduced from sixty-nine to forty-seven miles, and instead of the journey occupying, as at present, two hours and twenty minutes, an express will be able to do it in an hour. Dundee, likewise, will be brought to within fifty-nine miles of Edinburgh, and Aberdeen 130 miles, and no sea ferries will have to be crossed.

Within an hour after the ceremony of the opening had been completed, regular goods traffic upon the bridge had begun. Trains of mineral and goods waggons had been accumulating for some days on the lines in the vicinity of the bridge, and these were despatched across it in rapid succession during the evening of the opening day. Passenger traffic began on Wednesday, the 5th inst., between Edinburgh and Dunfermline. The delay

Digitized by Google

in the completion of the Glenfarg line has compelled the directors to defer the use of the bridge for the traffic to Perth and the North.

The amount mentioned by the Prince of Wales was the outlay upon the works. The total expenses of the work amount to a rather larger sum.

The total expenditure by the Forth Bridge Company upon construction has been as follows:—

Outlays on works to 31st December, 1889	£2,549,200
Add to this the amount expended in connection with Sir Thomas Bouch's suspension bridge (including all Parliamentary expenses).....	250,000
	£2,799,200
Parliamentary expenses in connection with cantilever bridge, engineering expenses, interest during construction, &c.....	378,006
Total expenditure to January 1, 1890.....	£3,177,206

It is estimated that a further sum of £50,000 will be required to complete the structure, the painting included.

For the erection alone of the Fife, Inch Garvie, and Queensferry piers the amount of wages paid, including salaries of officials in charge of the piers, amounted up to November 30, 1889, to £344,810. The total amount of wages and salaries paid on the works up to January 1, 1890, was £1,045,000.

The following is the estimated gain in point of time, due to the bridge, according to Mr. Acworth:—

From London to Perth:—

By West Coast.....is now 450 miles, will be 450 miles.
„ Midland Route „ 475¼ „ „ 455 „
„ East Coast „ 462 „ „ 441½ „
i.e., East Coast was 12 miles worse, and will be 8½ miles better than West Coast.

From London to Aberdeen:—

By West Coast.....is now 540 miles, will be 540 miles.
„ Midland Route „ 565½ „ „ 536½ „
„ East Coast „ 552 „ „ 523 „
i.e., East Coast was 12 miles worse, and will be 17 miles better than West Coast.

THE FORTH BRIDGE.

The twenty-eighth and final quarterly report of inspection by Major-General Hutchinson, R E., and Major Marindin, C.M.G., R.E., of the bridge over the River Forth has just been presented to Parliament. It runs as follows:—

We have the honour to report, for the information of the Board of Trade, that, in compliance with the instructions contained in your Minutes of the 26th October, 1882, and 4th February, 1890, and in accordance with the provisions of the Forth Bridge Ratlway Act of 1882, we have made our twenty-eighth and final inspection of the bridge over the Firth of Forth at Queensferry, which was commenced in April, 1883, and has just been completed.

The bridge, with its approach viaducts, has a total length of 8,295ft. 9in., and there are two spans of 1,710ft., two of 680ft. 6in., fifteen of 160ft., four of 57ft., and three of 25ft.

The approach viaduct at the south end, which is 1,993ft. 8in. in length, has four masonry arches of 57ft. span, and ten spans of 160ft. with steel lattice girders upon piers of granite, with concrete and rubble masonry backing. These piers have concrete foundations upon boulder clay or hard sandstone rock, and the highest of them has a height of 139ft. above ground level.

The approach viaduct at the north end, which is 980ft. 5in. in length, has three masonry arches of 25ft. span, and five spans of 160ft., with steel lattice girders upon piers, similar to those of the south approach viaduct. These piers have concrete foundations on greenstone rock, and the highest of them has a height of 130ft. above ground level.

The bridge proper, which is 5,321ft. 8in. in length, has two spans of 1,710ft. over the two deep water channels, one on each side of Inch Garvie, and two spans of 646ft. 4in., that at the south end being over shallower water, and that at the north end over dry land at North Queensferry.

The superstructure of these four main spans is composed of three great double cantilevers, built entirely of steel, the central or Inch Garvie double cantilever having a length of 1,627ft. 8in., and the South Queensferry and North Queensferry (or Fife) double cantilevers having each a length of 1,513ft. 9in.

The intervals of 346ft. 6in. between the north end of the South Queensferry cantilever and the south end of the Inch Garvie cantilever, and between the north end of the Inch Garvie cantilever and the south end of the North Queensferry cantilever, are each spanned by lattice girders, 350ft. in length, and 50ft. in depth at their centres, supported by the ends of the cantilever arms.

The compression members of the cantilevers are, as a rule, tubular, the principal ones having a diameter of 12ft., and the tension members are mostly lattice girders.

Each of the cantilevers rests upon a group of four low piers, built of masonry faced with granite, 49ft. in diameter (except the two north piers at North Queensferry, which are 45ft. in diameter), having their tops 18ft. above high-water mark. These piers are founded upon solid rock, or on concrete built up either from the solid rock or from a stratum of very hard boulder clay. They are arranged in pairs, 120ft. apart from centre to centre transversely across the bridge, and the north and south piers are 270ft. apart from centre to centre at Inch Garvie, and 155ft. apart at South and North Queensferry.

The south end of the southern cantilever and the north end of the northern cantilever rest upon granite piers, which also carry the ends of the adjacent girders of the two approach viaducts.

The four South Queensferry main piers are founded upon the boulder clay underlying the bed of the Firth upon the south shore, into which clay they are sunk to depths varying from 30½ft. to 45ft., and their bases stand at levels varying from 44ft. to 90ft. below high-water mark.

The four Inch Garvie main piers are founded under water upon greenstone rock, their bases standing at levels varying from 26ft. to 72ft. below high-water mark.

Of the four North Queensferry main piers two only are in the water, with their bases respectively 19ft. and 24ft. below high-water mark, the other two being upon dry land. The whole of them are founded upon greenstone rock.

The two cantilever piers are built of granite with rubble masonry backing; that at South Queensferry is upon the foreshore, and is founded upon boulder clay at a level of 34ft. below high-water mark, and that at North Queensferry is upon dry land, and is founded upon greenstone rock. The top of the former is 230ft. 3in. above ground level, and 208ft. 9in. above high-water mark, and that of the latter is 181ft. above ground level.

The foundations of all the piers are excellent, and the whole of the masonry is of a very superior quality.

The deepest foundation—that of South Queensferry north-east pier—is 90ft. below high-water mark, and the extreme height of the central portions of the three double cantilevers is 343ft. above the top of the piers, and 361ft. above high-water mark. The headway in the channels below the main spans is somewhat in excess of that required by section 5 of the Forth Bridge Railway Act, the actual minimum at high-water spring tides being as follows:—

	Ft.	in.
For 500ft.	150	10¾
„ 900ft.	128	8
„ 1,100ft.	108	9

The headway prescribed in the Act for these spaces is 150ft., 125ft., and 100ft.

The permanent way, which is for a double line, is on the cantilevers carried upon an internal viaduct supported by trestles resting upon the bottom members; at the central portions of the main spans it is placed between the girders, and upon the approach viaducts it is above the main girders. It is throughout laid in longitudinal steel troughs, resting upon cross girders, and acting as rail guards.

The rails are made of Siemens-Martin steel, and of a bridge form. They are in 28ft. lengths, and weigh 121lb. per yard; their ends being connected by joint plates 26in. in length. They are secured to the sleepers by wood screws, of which there are four at each joint in each rail, and twelve others placed 2ft. apart on alternate sides. The longitudinal sleepers are of Rangoon teak, 12in. wide and 6in. deep, bedded upon and secured to cross-bearers of teak, the spaces between which are filled in with creosoted pitch pine. Between the sides of the steel troughs and the longitudinals, teak wedges on the inside, and packing on the outside, have been inserted at every bearer.

The floor of the bridge is composed of steel buckle-plates, upon which a coating of gravel ballast is laid.

Proper and sufficient provision has been made for expansion and contraction both of the rails and of the main members of the bridge.

The whole of the superstructure of the bridge and viaducts, with the exception of the seven masonry arches, is composed of open-hearth or Siemens-Martin steel, which by the specification had to satisfy the following tests: Strips cut lengthwise or crosswise to have an ultimate tensile strength of not less than 30 tons, and not exceeding 33 tons per square inch of section, with an elongation of at least 20 per cent. on a length of 8in. for all steel subject to tensile stresses; and of not less than 34 tons nor exceeding 37 tons, with an elongation of at least 17 per cent. for all steel subject only to compression.

Strips cut crosswise or lengthwise 1½in. wide, heated uniformly to a low cherry red, and cooled in water of 82° Fahr., to stand bending double in a press to a curve of which the inner radius is one and a half times the thickness of the steel tested.

The requisite certificate, signed by the engineers, that these tests have been carried out is attached.

Under the authority of the Board of Trade, dated December 9th, 1881, $\frac{R\ 11,469}{81}$ = the bridge has been made of dimensions calculated to withstand a strain due to a rolling load of two trains of 50 loaded trucks drawn by two engines, giving a total weight for each train of 892 tons, and to a wind pressure of 56lb. to the square foot. Under the combined strains arising from these, and from the dead load, the steel, being of special quality, was authorised to be subjected to a stress of 8½ tons per square inch when in compression, and 7½ tons when in tension.

The stresses on the bridge, as constructed, have been carefully calculated, and are, as a rule, considerably below these amounts, in no case exceeding 7·6 tons in compression and 6·9 tons in tension, in the cantilevers; and 6 tons in compression, and 7·3 tons in tension, in the central girders.

The weight of steel actually used is 50,958 tons upon the main spans, and 3,118 tons upon the approach viaduct girders, making a total of 54,076 tons, of which 53,716 tons are riveted work.

The amount of masonry and concrete work is as follows:—
Granite, 640,300 cubic feet.
Concrete, 64,315 cubic yards.
Rubble masonry, 62,250 cubic yards.

At this, our final inspection, we have subjected every part of the bridge to severe tests, by running over it, and placing upon it, in various positions, two heavy trains, each made up as follows:—

	Tons.
Two engines and tenders (in front) each weighing 73 tons	146
Forty-four trucks loaded with iron, each 15 tons 10 cwt. gross weight	682
One engine and tender in rear	73
Total	901

Each of these trains covered a length of 896ft. 5in.

We have observed the deflections upon the main members, and other parts of the structure, and these have in all cases been smaller than might have been expected.

With the loads in positions calculated to produce the maximum deflections, these in no case exceeded 7·65in. at the ends of the cantilevers.

The deflections of the central girders, when loaded so as to produce the greatest effect, did not exceed 1·58in.

The deflections of the internal viaduct girders, approach viaduct girders, and cross girders were of a very moderate amount.

Careful observations were made to test the rigidity of the vertical members over the cantilever piers, and under the influence of the above heavy live loads the movements were very small, the "pull over" in the direction of the length of the bridge in no case exceeding 2in. at the top of the vertical columns. There appeared to be no appreciable movement of the top of these columns in a direction at right angles to the length of the bridge.

These results are most satisfactory, and, taken in conjunction with the theoretical strength according to the calculations and with the remarkable absence of vibration when the trains were running at considerable speed, prove that the bridge is one of exceptional strength and stability.

We are therefore able to report that the Forth Bridge may be safely opened for passenger traffic as soon as the approach railways have been completed.

The greatest wind pressures during the last quarter were registered on January 26th, 1890, and were as follows:—

On the large gauge at Garvie Castle, 18lb. per square foot.
On the small fixed gauge at Garvie Castle, 34lb. per square foot.
On the revolving gauge at Garvie Castle, 27lb. per square foot.

At the time of this gale the bridge was virtually completed, and the effect upon the structure is stated to have been no greater than would, according to calculation, be caused by a pressure of 10lb. per square foot over the whole surface. The maximum pressures during the progress of the work, of which there is a reliable record, were on the 16th November, 1888, when the three gauges above mentioned showed pressures of 27lb., 41lb., and 35lb. respectively.

The total number of fatal accidents during the seven years which the bridge has occupied in construction has been 56. Although this loss of life is greatly to be deplored, the fact that it has not been larger on a work of such magnitude, with so large a number of men employed in dangerous positions, shows that no reasonable precautions for their safety have been omitted.

In conclusion, we think it right to record our opinion that this great undertaking, every part of which we have seen at different stages of its construction, is a wonderful example of thoroughly good workmanship with excellent materials, and that both in its conception and in its execution it is a credit to all who have been connected with it, bearing testimony to the ability of the engineers who have designed it, to the skill and resource of those who have superintended and constructed it, and to the zeal and courage of the workmen who have been employed upon it.

APPENDIX.

FORTH BRIDGE.—STEELWORK.

We hereby certify that the whole of the steel used in the Forth Bridge has been made on the Siemens-Martin "open-hearth" system, and has been subjected to the following specified tests:—

Strips cut lengthwise or crosswise to have an ultimate tensile strength of not less than 30 tons and not exceeding 33 tons per square inch of section, with an elongation of at least 20 per cent. in a length of 8 inches for all steel subject to tensile stresses, and of not less than 34 tons nor exceeding 37 tons, with an elongation of at least 17 per cent. for all steel subject only to compression.

Strips cut crosswise or lengthwise 1½in. wide, heated uniformly to a low cherry red, and cooled in water of 82° Fahr., must stand bending double in a press to a curve of which the inner radius is one and a half times the thickness of the steel tested.

The results of the many thousands of tests made showed the steel to be possessed of toughness and ductility considerably in excess of the specified requirements.

FOWLER & BAKER.

February 14th, 1890.

Reviews.

MINUTES OF THE PROCEEDINGS OF THE INSTITUTION OF CIVIL ENGINEERS. Vols. XCVII. and XCVIII. 1889.

These bulky volumes of the Minutes of Proceedings of the Institution of Civil Engineers are so full of interesting matter, that within the limits at our disposal it would be impossible to adequately review it, and we can therefore only briefly notice a few of the more important subjects treated. The first paper published in these volumes is that by Mr. Gisbert Kapp, on "Alternate-Current Machinery," in which the author deals more especially with alternators, transformers, and motors. The most important problem which is investigated in the course of this paper is thus stated by the author: "Given an alternator, with excited field and running at a proper speed, and a pair of terminals, from which any desired strength of current can be obtained at a constant pressure, and having a frequency approximately corresponding to the speed of the alternator, what will be the condition under which the alternator will fall into step with the supply current, and what will be the relation between the current passing and the mechanical energy given off? Also, how will this relation be affected by variations in the strength of the field?"

The paper by Mr. Francis John Waring, on "Indian Railways: the Broad and the Narrow Gauge Systems Contrasted," again raises the question, on which sixteen years previously a memorable controversy took place within the walls of the Institution, as to the merits of different gauges. The author gives statistics, as to both cost of construction and working, for all the leading Indian railways, and shows that, notwithstanding the higher capital outlay per mile, the average net return was 1·262 per cent. higher upon the broad gauge than upon the metre-gauge railways. In the course of the discussion many of our prominent railway engineers seemed to be in agreement as to the disadvantages of a break of gauge; the desirability or necessity for light railways was admitted, but, it was argued, let such railways, however light, be constructed to the standard gauge, and then, if the traffic subsequently developed to such an extent as to render greater carrying capacity essential, heavier permanent way could be substituted for that originally laid down, and more powerful locomotives introduced, with corresponding rolling-stock, at much less cost than would be required if the gauge had to be increased. This reasoning commends itself, in our opinion, to all practical engineers, and we have no doubt that in general principle it is correct.

The following paper is by Mr. Charles Edward Emery, of New York, on "The District Distribution of Steam in the United States," and contains a brief historical sketch of the rise and development of steam distribution and a description of the plant of the New York Steam Company designed by the author.

Among the "selected papers" in Vol. XCVII. is an interesting account by Mr. Frederick Lobnitz of "The Removal of Rock under Water without Explosives," which has been adopted on the Suez Canal. Steel-pointed rock-cutting rams are adopted, which are raised to a height of from 5ft. to 20ft. and allowed to fall on the rock. Each of these rams weighs 4 tons, and five of them are arranged on either side of the central well of a dredger, through which the crushed rock is raised by the buckets. By means of this machine, the invention of Mr. Henry Lobnitz, shipbuilder, of Renfrew, from 10 to 15 cubic yards of rock could be broken to ballast size and raised by the dredger per hour. The author estimates that the cost of continuous working for a machine similar to the so-called "Dérocheuse" would be about 5s. per cubic yard, not including the transport of the broken rock in barges, nor the depreciation, interest, and insurance of the plant.

Turning now to Vol. XCVIII., we find the opening paper by Sir Nathaniel Barnaby on "Armour for Ships," than which, perhaps, few better subjects for controversy could be selected. As the event showed, it proved itself admirably adapted for bringing into prominence the extremely divergent views held by those who are responsible for the defence of our empire. Sir Edward Reed opened fire in his well-known style, pouring, metaphorically speaking, a broadside into the author, and simultaneously attacking Mr. W. H. White with his heavy sternchasers. The battle resolved itself, in the main, into a sort of triangular duel between Sir Nathaniel Barnaby, Sir Edward Reed, and Mr. W. H. White, enlivened by spirited attacks on the part of the naval officers present. Whether the proceedings were of such a nature as to inspire the general public with confidence may be doubted, but we would commend to its serious consideration the concluding remarks of Captain Fitzgerald: "Whatever might be the cost [of the navy], it could bear no reasonable proportion to the riches to be defended, and the only possible way of defending them was by absolute supremacy on the sea, both as to number and as to the individual fighting ships."

The next paper in the volume is by Mr. W. H. Greenwood, on the "Treatment of Steel by Hydraulic Pressure." The author superintended the construction, erection, and working of the complete plant used at the Abouchoff Works, St. Petersburg, for the fluid compression of steel on the Whitworth system. The paper contains an account of the process of fluid compression, with an explanation of its effect and advantages, and records of comparative tests carried out with pieces from pressed and unpressed ingots. As might have been expected, the opinion of the meeting, as expressed in the course of the discussion, in which many of the leading steel manufacturers took part, was by no means unanimously in favour of fluid compression. By several speakers of great experience in the production of steel it was contended that just as good results could be obtained without as with compression; and Mr. John W. Spencer went so far as to state that the strength of steel, taking tenacity and ductility together, was not dependent, as commonly supposed, upon the work done on it, but that simple castings could be produced possessed of all the qualities required of the best steel forgings, without any mechanical work having been put upon them, by simply conforming to the natural laws of crystallisation.

Among the selected papers is one on "Experiments on the Strain in the Outer Layers of Cast Iron and Steel Beams," by Mr. Edward Carstensen de Segundo, a student of the Institution. For this communication the Miller Scholarship was awarded in the session 1888-89.

THERMODYNAMICS, HEAT MOTORS, AND REFRIGERATING MACHINES. By De Volson Wood, C.E., M.A., Professor of Engineering in the Stevens Institute of Technology, New York. JOHN WILEY & SONS. 1889.

This is essentially a students' text-book, and has been prepared by Professor Wood to meet a want experienced by him in his course of instruction in Thermodynamics in the Stevens Institute of Technology, and this fact we have carefully borne in mind when reviewing it. A book of this kind is intended to give the fundamental principles of a subject and their theoretical and mathematical developments, in the first place as a mental training for the students, and in the second as an introduction to the more practical work of the drawing office or the engineering laboratory. To say that such a book is of no use to ordinary engineers is utterly beside the question. The majority of such engineers have blundered into their knowledge of principles through a long practical experience, and while they may not know how these may be expressed exactly, they have a fair knowledge of their bearings on their practice, and they speak science every day without knowing, for science is nothing more than concentrated experience and common sense. We do think that sometimes professors allow their theories to run off with them, but in its proper place we cannot have too much of theory, for it is very often an apparently insignificant theoretical consideration which has most important practical bearings.

Understanding, therefore, that Professor Wood's book is meant for students, and is introductory to the more practical applications of the subjects, we have no hesitation in saying that he has simplified many parts which have hitherto puzzled students, and that his book, if used as a text-book, and accompanied by other instruction of a more practical nature, is a decided advance, in some respects, on the books on the same subjects which have preceded it. Professor Wood is evidently a great admirer of Professor Rankine, and his chief object has evidently been to lead his students up, by an easy and uniformly guided path, to Rankine's height, and at the same time familiarise them with the way, by a free use of illustrations, exercises, historic references, and numerical examples. These latter are very important features in the book, and should be of great use to the students in impressing the meaning of the different formulæ on their minds, and in enabling them to extend their reading to the original memoirs of the men who laid the foundations of the science. Professor Wood has, however, not confined himself to a mere amplification of the works of his predecessors, but has in some cases introduced new methods of presenting the subjects. For instance, that part of the book relating to "Entropy," or the "Thermodynamic Function," which has hitherto puzzled the ordinary student, is presented in a comparatively simple manner. We say comparatively simple manner, but it must be remembered that thermodynamics is a difficult science, and the modern young man should be given to understand that unless he is prepared to make a mental effort he had better leave it alone.

Our space will not allow us to make a detailed examination of the book, but we may say that we have looked over it with a considerable amount of satisfaction. The part relating to the principles of thermodynamics is a good *résumé* of our present knowledge of the subject, although, as might be expected, some of the definitions and explanations may be open to criticism, as indeed would any other definitions and explanations whatever, for we are still far from finality in such matters. The parts relating to heat engines and refrigerators form the basis for the more practical applications; they give in short the physics of the subjects. The practical use of some parts of these may not be evident to the young student, but he may rest assured that in the meantime their study will afford him a most useful mental exercise, and that when he becomes an engineer he will find it of the greatest advantage to be armed with all the appliances of well-based theory, for the engineer of the future will be a man who sees the bearings of his theories on his everyday work. The engineer of the past and the present has been too often one who has groped his way through trial and error, and he ought to recognise the necessity for a more thorough preliminary training. We must repeat our warning, which we have on previous occasions given to the professors, that they must remember that the chief object of their existence is to train engineers, and that, while we cannot have too much sound theory, that there is a time and place and due amount for everything, and by overloading their courses of instruction with too much mathematics they may prevent the really useful parts of their work from being appreciated.

KALENDER FÜR ELECTROTECHNIKER, 1890. F. Uppenborn. R. OLDENBURG, Munich and Leipsic.

This is the seventh year of this well-known annual. It is bound with flap cover as a pocket-book, measuring 6½in. by 4½in. by ⅝in., and contains about 300 pages of small but clear print. It is singularly complete, and seems to contain all the data an electrician could possibly want, and some things he certainly would not, such as the dimensions of the earth, and the combination heats of compounds quoted without reference to their physical states. Therefore, though we have not found anything left out that ought to have been put in, there are many things which might be omitted. Too much is said perhaps about the apparatus made by the firm of Siemens & Halske. The Pear Oil Lamp, for instance, is of no use as a standard, as its light is too yellow. Engineers do not measure currents with sine or tangent galvanometers. The tables and data of commercial dynamos, lamps, and secondary batteries, though they appear in most pocket-books, are of little value. We mention these points merely as suggestions for the next edition, and not with the intention of finding fault. Herr Uppenborn has really condensed into a small book an enormous amount of useful information, and we think it is as complete and universal as such a pocket-book could be.

TRAITÉ ÉLÉMENTAIRE DE L'ÉNERGIE ÉLECTRIQUE. Par E. Hospitalier. Tome I. Paris: G. MASSON. 1890.

This is the first volume of a book that has been wanted for a very long time. As electrical engineering has advanced, the necessity for what is narrowly called the theoretical knowledge increases, and the engineer finds that he must either confine his attention to books written by men with the same sort of training as himself, which do not give him the information he requires, or must wade through works written entirely from an academical point of view, which give him some of the information he wants, but deal with so much that is quite useless to him, that the return is hardly worth the labour spent.

M. Hospitalier now comes forward with a book intended to supply just what is wanted. The first volume is a sort of complete text-book of electricity, and errs rather on the academical side, too much of it being of the ordinary text-book type. Advanced mathematics are nowhere employed, while the author does not cripple himself by avoiding mathematical treatment altogether. Everyone acquainted with M. Hospitalier's style will expect the book to be written as clearly as the subject admits, and will not be disappointed. The introduction of such expressions as specific resistances in ohm centimetres is typical of the way he treats his subject. The only fault worth mentioning is that the author discusses far too many methods, phenomena, and instruments which are of no importance to electrical engineers. What is required is to give just as much of what generally appears in such treatises as that of Mascart and Joubert, or of Jamin and Bouty, as is needed by an electrical engineer, and nothing more.

M. Hospitalier's second volume will be even more difficult to write. We sincerely hope that we shall not have dynamos with empirical laws, and all sorts of curves which are never used in practical design, and transformers with coefficients of self and mutual induction, and leads following the interest on capital law.

The price of the present volume is exceedingly low for what it contains.

ELECTRIC LIGHT INSTALLATIONS, AND THE MANAGEMENT OF ACCUMULATORS. By Sir David Salomons, Bart. London: WHITTAKER & Co. 1890.

Sir David Salomons is well known as an enthusiastic electrical engineer, and the preparing of this work seems to have been to him a labour of love. There is a great deal of miscellaneous information about small points, and no doubt a book of this kind finds numerous readers among amateurs who have installations of their own, or who are thinking of doing so, and take a personal interest in the matter. There are a great number of technical mistakes, more especially when the author discusses the chemistry of accumulators. We find such substances as SO, SO_2, PbO_4 playing prominent parts in the reactions in accumulators. These may be misprints, but the whole of the chemical part is incorrect. We believe Sir David Salomons is not responsible for the theory that Pb_2SO_5 is formed and reduced by charging to the more healthy form $PbSO_4$. The method of charging cells while running on lamps given by the author is unnecessarily complicated. We may also mention that a special shunt machine, with little field excitation, which gives nearly constant current on cells, should be used for charging accumulators.

The work will be, and in the various earlier editions has been, very useful to amateurs, and will, we have little doubt, run to a sixth edition, as it deserves.

CLYDE SHIPBUILDING IN FEBRUARY.

THE output of tonnage from the Clyde district during February amounts in the aggregate to 38,708 tons, which is considerably larger than the production during the corresponding month in any year since the shipbuilding industry was started on the Clyde. The majority of the vessels put into the water are of a superior class, and of considerable tonnage, there being five of over 3,000 tons each. The largest was the Hamburg-American liner "Normannia," built by the Fairfield Shipbuilding and Engineering Company, Govan, in which considerable interest is being centered at present. She is the largest merchant steamer ever constructed in the Fairfield establishment, and exceeds the tonnage of the Cunarders "Umbria" and "Etruria" by about 780 tons. Her dimensions are 500ft. by 57ft. 8in. by 38ft., and her tonnage 8,500 tons. She will be fitted with engines capable of developing 14,000 i.h.p. The guaranteed speed is 19 knots, and it is confidently expected that this speed will be maintained continuously at sea.

There is no scarcity of contracts in hand, and quite a large number of vessels are in a very forward state. This condition of things will certainly ensure a large output for the next month or two, providing that the present cheering relationship which exists between employers and employés continue. The prospects, however, are by no means encouraging, as the falling off in inquiries for new vessels, which set in a month or two ago, still continues; in fact, many shipbuilders have not had a single inquiry. The contracts secured during the month make up a total of about 3,500 tons, the most important order being for a four-masted sailing ship, which is to be built by Messrs. R. Duncan & Sons, of Port Glasgow, for Glasgow owners.

The following are the particulars of the vessels launched:

SINGLE-SCREW STEAMERS.

By the Ailsa Shipbuilding Co., Troon:—"Kasara" (steel), 1,125 tons, 1,800 i.h.p. Engined by Messrs. Dunsmuir & Jackson, Govan. Owners, British India Steam Navigation Co., for their Indian coasting trade.

By Messrs. Barclay, Curle, & Co., Whiteinch:—"Benares" (steel), 3,010 tons, 2,700 i.h.p. Owners, the Hamburg-Calcutta Co.

By Messrs. Blackwood & Gordon, Port Glasgow:—"Alfred Dumois" (steel), 650 tons. Engined by the builders. Owner, Mr. Jacob Christensen, of Bergen, for the West Indian and United States fruit trade.

By Messrs. Caird & Co., Greenock:—"Netherby Hall" (steel), 3,200 tons, 2,000 i.h.p. Engined by the builders. Owners, Messrs. R. Alexander & Sons, Liverpool.

By Messrs. David J. Dunlop & Co., Port Glasgow:—"Cyrnos" (steel), 900 tons, 1,700 i.h.p. Owners, Messrs. Fraissinet & Co., Marseilles, for the Mediterranean trade.

By Messrs. D. & W. Henderson & Co., Partick:—"Bellagio" (steel), 4,000 tons, 2,500 i.h.p. Engined by the builders. Owners, Messrs. Bell Brothers & M'Lelland, Glasgow, for general trade.

By Messrs. A. & J. Inglis, Pointhouse:—"Palamcotta" (steel), 4,000 tons, 3,000 i.h.p. Engined by the builders. Owners, British India Steam Navigation Co., for their Indian trade.

By Messrs. Murray Brothers, Dumbarton:—"Oakland" (steel), 400 tons. Engined by Messrs. Kincaid & Co., Greenock. Owner, Mr. T. W. Yeager, Richmond River, N.S.W., for the timber trade.

By Messrs. Russell & Co., Greenock:—"Strathesk" (steel), 2,300 tons, 1,100 i.h.p. Engined by Messrs. James Howden & Co., Glasgow. Owners, Messrs. Burrell & Sons, Glasgow, for general trade.

By Messrs. Scott & Co., Bowling:—"Cornelian" (steel), 369 tons, 445 i.h.p. Engined by Messrs. Muir & Houston, Glasgow. Owner, Mr. W. Robertson, Glasgow.

By Messrs. Scott & Co., Greenock:—"Yunnun" (steel), 1,650 tons. Engined by the builders. Owners, the China Navigation Company, London.

TWIN-SCREW STEAMERS.

By the Fairfield Shipbuilding and Engineering Company, Govan:—"Normannia" (steel), 8,500 tons, 14,000 i.h.p. Engined by the builders. Owners, the Hamburg-American Company, for their Atlantic service.

By the London and Glasgow Shipbuilding Company:—"Nau-Chang" (steel), 1,750 tons, 1,600 i.h.p. Engined by the builders. Owners, the China Steam Navigation Company, for the China coasting trade.

By Messrs. A. McMillan & Sons, Dumbarton:—"Planeta" (steel), 1,500 tons. Engined by Messrs. M. Paul & Co., Dumbarton, for English owners, and intended for the Brazil coasting trade.

By Messrs. Murdoch & Murray, Port Glasgow:—"Pilcomayo" (steel), 450 tons, 150 i.h.p. Engined by Messrs. Rankin & Blackmore, Greenock, for London owners, and intended for the South American trade.

PADDLE STEAMER.

By Messrs. Wm. Denny & Bros., Dumbarton:—"Clacton Belle" (steel), 450 tons. Engined by Messrs. Denny & Co., Dumbarton. Owners, Clacton-on-Sea Steamboat Company, for passenger service between London and Clacton.

STEAM LAUNCH.

By Messrs. Davie & McKendrick, Govan:—"Alexandra," 4 tons, 20 i.h.p. Engined by Messrs. Ross & Duncan, Govan.

SAILING VESSELS.

By Messrs. Russell & Co., Port Glasgow:—"Strathgryffe" (steel), four-masted barque, 2,200 tons. Owners, Messrs. J. & W. Stewart, Greenock.

By Messrs. Alexander Stephen & Sons, Linthouse:—"Mayhill" (steel), four-masted barque, 2,050 tons. Owners, Messrs. W. & J. Myles, Sons, & Co., Liverpool.

In addition to the above Messrs. T. B. Seath & Co., Rutherglen, constructed two galvanised steel barges, each of 100 tons, which were shipped in pieces to South America.

ADAMS' AUTOMATIC BOLT CUTTER.

WE illustrate on page 235 a 1½in. Adams' automatic bolt-threading and nut tapping machine, made by the Capitol Manufacturing Company, Chicago, U.S.A.

The automatic operating device consists of a cam groove on the head, a spring-seated actuating pin, and returning cams for the pin. The operating action is controlled by the adjustable collar fixed on a rod attached to the sliding carriage, and is operated to release the actuating pin during the feed of the carriage. The closing of the head is accomplished by the rear adjustable collar on the same rod operating a closing lever as the carriage is returned to position. The head is made entirely of steel and consists of four parts only. The dies are removable and easily adjusted, but as rigid when adjusted as if set in a solid die machine. The dies can be cut in a dummy head attached to any lathe, and made ready for use without occupying the cutter head. The dies, as will be seen, are clamped rigidly by means of the face screws. These screws have only to be loosened in order to remove or put in the dies. Each die is independently adjustable either way. The accurate adjustment of the die is ensured by a circle on the face of the head and completed by the arc of the same circle cut in the dies when they are hobbed or re-hobbed in the dummy head.

The carriage, which is double the length of the ordinary carriage, is gibbed to take up the wear; the vice jaws are placed in the centre of the carriage, in order to secure stability and accuracy.

All the machines are provided with an automatic force pump, which is operated by an eccentric and throws a steady and large stream of the lubricant into the head. To insure a steady stream, an air chamber is attached to the feed pipe. The base of the machine is made very heavy and all the bearings are very long. The nut taps or nut-clamping attachment is arranged to admit of from two to four nuts on the cutting edge of the tap at one time, thus increasing the product about three-fold. We are indebted to the *American Journal of Railway Appliances* for our illustration.

THE WEYMERSCH PRIMARY BATTERY.

THE Weymersch Electric Battery Syndicate have on view at No. 2, Victoria Mansions, an installation of their system for illustrating what can be done in electric lighting without a dynamo. It is, of course, only meant for use on scales too small for engines and dynamos. The installation which we recently inspected consists of eight standard batteries each fitted in a teak case measuring about 2ft. 8in. by 9½in. by 1ft. 4in. Each case contains six cells, each cell being divided into a central porous receptacle to contain one carbon element, 7½in. by 6in. by ½in., and two outer receptacles to contain two zinc elements, 7⅛in. by 7⅛in. by ¼in. The six porous cells are connected together by an ebonite pipe terminating outside the teak case in an ebonite tap and gauge glass, so arranged that on filling the porous cells with the depolarising liquid the level of solution is at once seen upon glancing at the gauge glass. The outer cells containing the zinc elements and exciting liquid are likewise connected to another ebonite pipe with its outside tap and gauge glass for a similar purpose.

The battery will work 18 consecutive hours without requiring the depolarising solution to be changed, but where the time of running is only a few hours at a time it is preferred to only fill the porous cells partially, sufficient to last the time required. Of course the oxidising liquid must be run off at the termination of the run to prevent local action on the zinc plates. The latter solution is dilute sulphuric acid one to twenty.

The general arrangement of the batteries has been designed with a view to economising labour and attention. They can be charged or emptied of their contents in five minutes by merely opening the proper taps. Barrels containing the solutions, holding from 6 to 40 gallons, are fixed at a higher level than the batteries; india-rubber tubes lead the liquids from the taps of the barrels to the cells, the filling of the whole six cells being simultaneous by reason of the connecting pipe mentioned above. A continuous trough fixed under the taps from each battery gives the necessary means of emptying without trouble and mess.

Each standard battery of six cells has a total internal resistance of 0·30 ohms, giving a maximum current of 15 amperes for 12 hours.

The oxidising solution is a secret. This seems to be the chief objection to the battery. Probably every depolarising agent is known to chemists. Battery inventors ring changes on chromates, permanganates, and nitric acid, or on lead peroxide, manganese peroxide, copper oxide, and perhaps ferric salts, or easily reducible silver and mercury salts, and nitric acid. If Mr. Weymersch has a new depolariser, why not patent it? if an old one, where is the advantage? Probably the battery is one of the best of its kind, as so much care is taken in designing it so as to be easy to work. We would have much more confidence in it if we knew what the depolariser is. A battery made up with, say, a cheap chromate, should have a large sale, as the difficulties so far have not been chemical, but have resided in the trouble of filling, cleaning, and keeping a battery in order.

THE INSTITUTION OF ELECTRICAL ENGINEERS.

THE meeting of this Institution on the 27th ult. was occupied by the discussion on Mr. Swinburne's paper, "The Theory of Armature Reaction in Dynamos and Motors," and on Mr. Esson's paper, "Some Points in Dynamo and Motor Design."

Professor Ayrton, referring to Mr. Swinburne's method of treating the subject, deprecated the use of the term "magnetic potential" where difference of magnetic potential was meant. He also thought Mr. Esson's term "working saturation" was not to be recommended and that "working induction" would be much better. In his further remarks, Professor Ayrton said he would confine himself chiefly to three heads, which were brought out prominently in a paper on "Electromotors" by Professor Perry and himself in 1883, and about which considerable difference of opinion still existed. These were—1st, The existence of magnetic lag; 2nd, The alteration of resistance of revolving armatures by self-induction; and 3rd, Motor construction for minimum weight. As regards magnetic lag, this, he said, had often been denied, but quite recently Professor Ewing had shown that such a lag did occur, amounting in some cases to several minutes. With reference to the increased resistance of revolving armatures due to self-induction, he thought some misunderstanding existed, for Mr. Swinburne in his paper said that "power cannot be lost by self-induction." In their original paper, Professor Perry and himself had given a formula for calculating this loss when the brushes were placed at the neutral position, and this they confirmed experimentally. When, however, this condition is not fulfilled, a modification is necessary. If the brushes could be placed at an absolutely non-sparking position, the resistance of the armature would not be increased by rotation, for then a section leaves the brush and is thrown into circuit with the proper current in it, and hence no further e.m.f. is needed to bring the current up to its proper value. In fact, the energy used in starting the current is supplied by the belt whilst the coil is short-circuited. Experiments on the characteristics of a magneto Gramme, used as a generator and as a motor with equal lead and trail, show that as a dynamo the curve falls, whereas as a motor the curve rises, with increase of current. On trying the same experiments with a separately excited Gramme, the e.m.f. as a motor always increased with the current through the armature whatever the strength of exciting current used, but as a generator the e.m.f. always decreased, and with a weak field became negative when the armature current increased. In conclusion, Professor Ayrton contended that the above experiments proved conclusively that a relatively powerful armature strengthens the field of a motor and weakens that of a dynamo.

Mr. Ravenshaw said that as regards Mr. Esson's expression for the ampere turns which may be carried on an armature, he could not say that it held good in practice. He himself had experimented a good deal on the subject, and the results seemed to point to the fact that for all sizes and shapes of well-designed machines, their behaviour at the brushes would be very similar when the

Digitized by Google

ratio between the ampere turns and the total induction in the armature was the same. This he gave, not as a law, but as a result of his own experience. This experience, however, did not agree with that of Mr. Esson. One machine made for 4,000 watts, on which he had made many experiments, had a very small distance between the pole pieces and armature core, and the pole pieces were rather close together. After testing it under these conditions up to 6,000 or 7,000 watts he tried it with the field bored much larger, and also with the poles cut off until they embraced an angle of 90°. Under all these conditions the maximum ampere turns it would carry without sparking appeared to be the same, the armature induction being kept constant. This machine was afterwards wound with a drum armature, and he had built two other types of machines with the same area of armature core, both of which carried the same ampere turns.

Mr. Kapp stated that the two papers under discussion would form very important landmarks in the development of the dynamo, and said the subjects treated in them had been brought into prominence by the use of large machines. According to Mr. Swinburne, the limiting diameter of armatures in two-pole machines was about 40 centimetres, but he (Mr. Kapp) had, by increasing the dimensions of all the parts proportionately, made dynamos with 50 c.m. armatures, and others had gone still higher. Referring to formula (2) in Mr. Swinburne's paper, he asked whether the coefficient M was correct, for, as given, the length of the armature was not taken into account. His own experience gave coefficients varying from 0·12 to 0·18 instead of from 0·08 to 0·085. As regards reversing pole pieces he said that they were brought out about five years ago by Mather. Coming to Mr. Esson's paper, Mr. Kapp wished to add one device for equalising the field in single magnet machines which had been omitted from the interesting collection. This device consists in making the upper horns rather longer than the lower ones. He cordially endorsed Mr. Esson's remarks on the small rise of temperature allowed by the Admiralty, for a rise of 11° C. meant enormous machines for their output. On the other hand, he usually allowed more cooling surface than Mr Esson, his rule being 1·5 and 2·5 square inches per watt wasted in armature and magnets respectively.

Mr. Farquharson said he thought the Admiralty rule for limiting rise of temperature had been misunderstood, and in Mr. Esson's paper it was wrongly stated, for the rise permitted was 30° F. and not 11° C. The method of testing adopted by the Admiralty was to take the temperature outside the insulation immediately the machine was stopped. This temperature was by no means the same as that within the conductor, for he had known the outside temperature to rise for 20 minutes after the machine was stopped. Keeping this fact in view, together with the long continuous runs (sometimes amounting to 24 days and nights) to which ship lighting dynamos may be subjected, he thought the Admiralty were justified in fixing the limiting temperature low enough to be safe for all machines.

Mr. A. T. Snell, speaking of machines run as dynamos and as motors, said he always found it possible to get a greater output at a given speed when running as a motor, and that the trail as a motor was always less than the lead as a dynamo. Another point in which motors differed from dynamos was the possibility of using very thick brushes with advantage in the former, whereas in the latter such a proceeding proved disastrous. These differences seemed to him to show that the magnetic distribution in generators and motors are not the same, and that in dynamos the field was more straggling and subject to greater distortion.

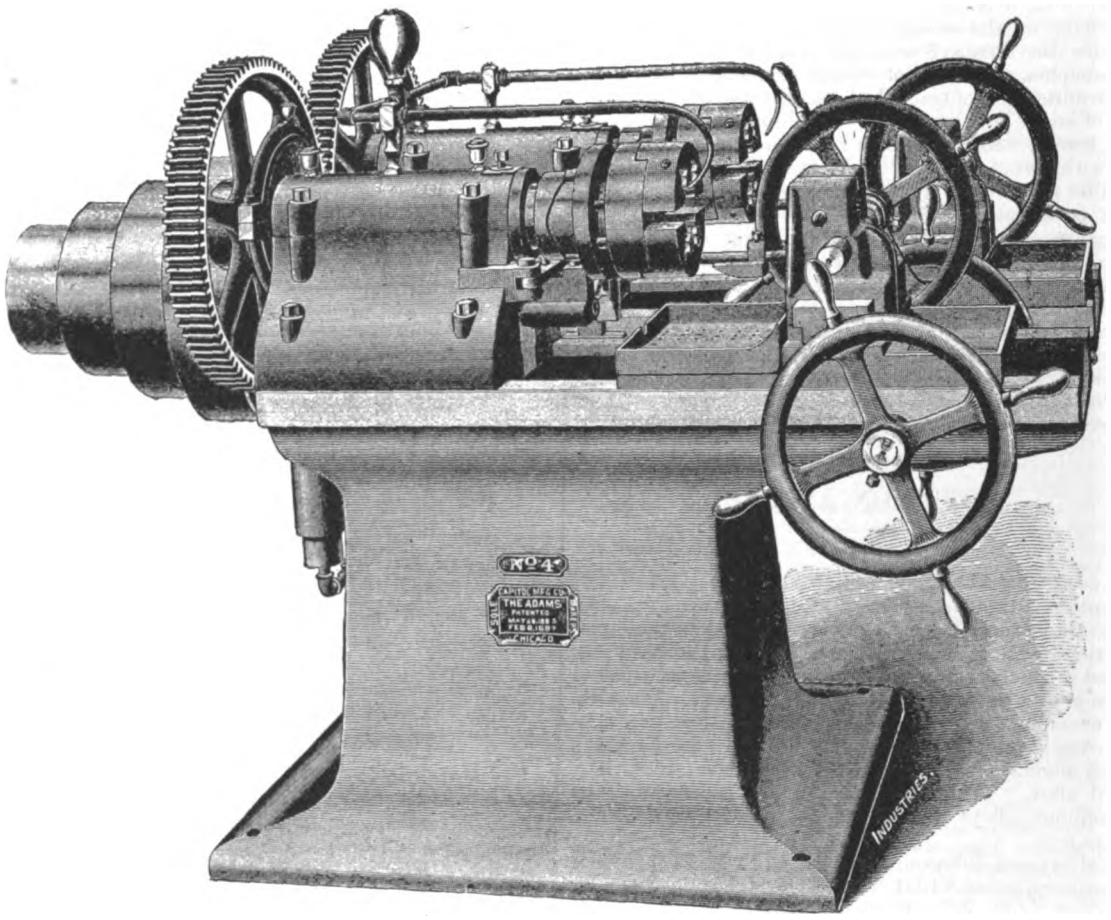
The discussion was then adjourned to the 13th inst.

THE NATIONAL ELECTRIC LIGHT ASSOCIATION OF AMERICA.

(*From our New York Correspondent.*)

The eleventh meeting of this Association was held at Kansas City, Missouri, on the 11th, 12th, 13th, and 14th of February. President Weeks, in his opening address, referred to the growth of a more fraternal feeling between the electric light and power engineers and the telegraph and telephone representatives since the reorganisation of the society in 1885. He also noted the example set by our British brethren of adjusting differences amicably instead of carrying litigation to the final Courts. Such a policy, he said, would have saved hundreds of thousands of dollars in America, and would have enhanced the value of electrical securities. He deprecated the policy of competing companies entering upon territory already occupied. The report of the committee on a petition to Congress for the abolition of the duty of four cents per pound on copper reported that they had performed the work assigned to them. Not a word had been said by anyone in defence of the duty, and there seemed little probability of its remaining very long. The committee on underground work, not having been able to accomplish anything, was discharged at the request of the chairman. The committee on the standardising of potentials for street railway work had received replies to their circular from 85 per cent. of the electric railway companies. About 90 per cent. of the lines operated used the Sprague and the Thomson-Houston systems. Out of about 80 in operation only nine were supplied with current from electric lighting stations. The potential now used varied from 220 to 800 volts, the greater proportion of the companies using from 450 to 550 volts. Both the Sprague and Thomson-Houston companies had agreed to a standard of 500 volts, excepting where special apparatus may be required. The committee does not recommend that it be understood that the same machinery can be used at central stations for furnishing light at night and power by day. The great saving for the Central Station Company lies in the reducing of labour and fixed charges, and also that the reserve power for one will suffice for the other. The committee on harmonising the interests of the insurance and electric lighting companies recommended that the latter appoint instructors for the term of one year to teach insurance inspectors to judge of the fire hazards of electrical installations. This recommendation had not, however, met with the favourable responses anticipated; although the underwriters appear to be willing to take some steps in the direction of more harmonious relations. A plan was also submitted for the organisation of a mutual insurance company, which would lead, not only to a reduction in the cost of insurance, but also to the construction of a better class of central stations, and their frequent inspection by experts. The report of the committee was adopted.

Papers were read by Mr. C. J. H. Woodbury, of Boston, on the "Construction of Central Stations;" by Mr. Fred. E. Sickles, on "The Steam Engine"; by Mr. George H. Babcock, on the "Economical Generation of Steam for Electric Light Stations"; by Mr. C. J. Field, on the "Development of Generating Stations for Incandescent Light and Power"; and by Mr. T. Carpenter Smith, on "A System of Station Accounts." All of these papers were thoroughly discussed, but brought out no important facts of general interest, being simply a reiteration of well-known practice in the lines of steam and electrical engineering. Mr. A. J. De Camp, of Philadelphia, addressed the meeting on the "Cost of Products to Central Stations," which was followed by a paper entitled "Nine Years with the Arc Lamp," by Mr. M. D. Law, of the same place. In a paper on "Carbon Tests," Mr. E. F. Peck pointed out that, according to tests made by himself, it was shown that in a station operating a thousand arc lamps there was a saving of sixty-five electrical horse-power per hour in using the best rather than the poorest carbons. There was also a saving of 29 per cent. in carbon consumption. A paper, under the title of "How our Paths may be made Paths of Peace," by Mr. Henry W. Pope, of Elizabeth, N.J., then followed.



Professor Elihu Thomson, of Lynn, Mass., presented a paper on "Safety, and Safety Devices in Electric Installations." He asserted that there is more danger to life from an alternating than from a continuous current of equal pressure. He was also just as firmly convinced that the fire risk was less with alternating than with continuous currents, assuming the work of installation to be equally good. We would not be able to utilise water power for lighting without employing pressure of potential sufficient to convey the energy to a distance over a conductor at a moderate cost. If great saving of cost of fuel and other expenses in operating one large steam plant, instead of a number of separate plants, with their attendant risks, in large cities is an object worth seeking, it would be found in the conveyance in electric energy at fairly high pressures.

The paper by Mr. Frank J. Sprague, of New York, on "Electricity as Applied to Railways," was historical, and attempted to be prophetic. Two years ago, he said, the electrical railway business was in an experimental stage, and it was difficult to get a dollar for investment, while to-day it demands the best thought and the most active energies of two great corporations and a number of smaller ones. The business done this year would probably amount to $6,000,000. He stated that there were about 130 towns in the United States with one or more electric railways in operation, construction, or under contract, comprising 1,500 miles of track, equipped with about 1,700 motor cars requiring 3,000 motors of an aggregate capacity of 45,000 h.p., and a daily mileage of about 100,000, which would be doubled within three months. Reviewing the work of the past two years, that which was promised for electricity had been, in the main, entirely fulfilled. Gradients of 12½ per cent., and more recently of 14 per cent., had been ascended with loaded cars. Gradients three miles long, varying from 4 to 8 per

ADAMS' AUTOMATIC BOLT CUTTER.

CONSTRUCTED BY THE CAPITOL MANUFACTURING COMPANY, CHICAGO, U.S.A.

(*For description see opposite page.*)

Digitized by Google

cent., had been ascended by a motor car pulling a tow car. It had done this work where it would have been impossible to have done it by horses. It had enabled the running speed of cars to be increased 50 per cent. even in crowded cities, and on suburban routes speeds of twenty miles or more had been made. The electric car had shown that it can run faster on both up and down gradients; that it can be got under way and stopped more quickly than a horse car. Mr. Sprague then devoted considerable attention to the probable utilisation of electricity on the ordinary steam railroad, taking as an example the Pennsylvania line between New York and Philadelphia, a distance of 90 miles; and, assuming that the requirements of traffic had necessitated the construction of an air line double track in addition to the present four tracks, with two copper rods, each 1in. in diameter, and with four stations, 22½ miles apart, a train service of 60 miles per hour every ten minutes would be possible at a potential of 900 volts. He believed that this system would be so far superior to that now existing as to practically revolutionise travel between the two points. He hoped that it might be a fact in the not distant future.

Papers were read by Mr. C. C. Haskins, of Chicago, on "Prodigality in Economy"; by Mr. Charles A. Harber, of Kansas City, on "Line Insulation from the Standpoint of Practical Experience"; and by Mr. J. E. Lockwood, of Detroit, on "How to Make Arc Light Circuits Safe."

NOTES ON ALLOYS.

II.

Aluminium alloys are still receiving a good deal of attention, although at present we have no accurate data as to the nature of these compounds. Before the introduction of cheap aluminium several alloys had been prepared in the laboratory, and certain characteristic points were put on record concerning their nature. Bismuth, for example, when added in small quantities, produced an exceedingly brittle alloy, while the addition of a small amount of aluminium to tin yields an elastic and hard alloy. Those interested in the earlier work on aluminium alloys will be glad of the following references:—

Calvert and Johnson, *Phil. Mag.* [4], X. 240; Tissier, *Comptes-Rendus*, XLIII. 885, XLIX. 54; Debray, *Comptes-Rendus*, XLIV. 925; Wohler, *Annalen der Chemie*, CVI. 118, CXIII. 248, CXXXVIII. 258, and *Poggendorff's Annalen*, XI. 161; and a paper by Michel, in *Annalen der Chemie*, CXV. 102.

Two or three investigators have recently re-examined the aluminium amalgam, which was first described by Cailletet (*Comptes-Rendus*, XLIV. 1250), and in our report of the British Association meeting of last year we gave an abstract of the work done by Dr. J. B. Cohen with this alloy (*Industries*, Vol. VII., p.430). The amalgam has a very energetic action on water, forming alumina and evolving pure hydrogen, and is used by the author for various chemical operations in which a powerful reducing agent is required. It reduces nitrates and nitrites to ammonia, and can be used therefore in water analysis, and rapidly converts nitrobenzene into aniline. Baille and Féry have also recently examined this aluminium amalgam, and in their paper in the *Annalen* [6], XVII. 246, they describe experiments which show that aluminium dissolves more rapidly in hot mercury than cold, but that mercury vapour does not attack the metal. They have also succeeded in obtaining the amalgam in a crystalline form, and have found that it has the composition represented by the formula Al_2Hg_3. As this is the first definite aluminium alloy described, it will be interesting to note whether the copper and other alloys contain a compound having a similar constitution. The amalgam dissolves in nitric acid, although this acid has no action upon the pure metal, which also supports the conclusion that a definite compound is produced. Another important fact brought out by these experiments of Baille and Féry seems likely to throw light on the formation of the triple aluminium alloys, such as that containing copper and iron patented by Brin. It appears that when aluminium amalgam is added to antimony amalgam, the antimony separates at the surface in small crystals, but when aluminium amalgam is added to lead amalgam, the aluminium separates from the mixture. It is also known that aluminium is expelled from its alloys with copper and tin when lead is added to the fused alloy, so that there is little chance of forming a simple or triple alloy containing aluminium and lead.

One of the numerous methods for the electrolytic preparation of aluminium also is based on the fact that aluminium and lead do not alloy together. Roger, by electrolysing fused salt and using a lead cathode, obtains a lead sodium alloy, and then uses this alloy as a cathode in the electrolysis of cryolite. The aluminium separated in the electrolysis of the cryolite, although separated on the lead cathode, will not alloy with it, and can subsequently be readily separated. The Brin patents (1888, Nos. 3547, 3548, 3549, 8746, and 8747; 1889, No. 15508) appear to show that aluminium vapour alloys readily with hot metals, although Baille and Féry have found that mercury vapour does not attack solid aluminium. In their last patent they use a flux consisting of bauxite, borax, and salt, which is fused in a specially constructed furnace, which allows of the introduction of an inert gas to carry the metallic vapours formed by the dissociation of the aluminium chloride produced into a separate chamber, where they come in contact with the metal with which it is desired to make an alloy. The furnace is an electric one, and is worked at either a high potential (50–100 volts), or a low potential of 2 or more volts. In the former plan an arc is formed at the surface of the fused flux, which considerably increases its temperature and brings about dissociation through heat, which aids the electrolytic reduction, while, when worked at a low potential, the fused mass is simply electrolysed, a button of sodium aluminium alloy gradually accumulating at the bottom of the crucible. Parsons has urged the advantages to be derived from adding aluminium to the copper alloys, which at present contain none of this metal, and thereby lessen their corrodibility, increase their fluidity, and augment their strength. In his patent (No. 187, 1889) he suggests preparing, in the first instance, ingots of an alloy containing 100 parts by weight of iron, 50–105 of tin, 5–40 of manganese, and 3–50 of aluminium. He then adds from 1 to 5 parts of this alloy to the copper, brass, bronze, or gun-metal which requires treatment. In the case of bronze or gun-metal the quantity of tin may with advantage be increased, and a greater quantity of manganese (even ferro-manganese) may be used with these alloys than with brass.

Notes.

THE SALOMONS SCHOLARSHIP.

Sir David Salomons has offered to devote £1,000 to the foundation of an electrical engineering scholarship. This will furnish a scholarship of £30 or £40 a year. The management of the matter is left in the hands of a committee of the council of the Institution of Electrical Engineers. Sir David Salomons' generosity in this matter has resulted in one of the most public spirited actions which has yet been done by electrical engineers, and there is little doubt the scheme will be as effectual as it deserves.

INDUSTRIES IN QUEENSLAND.

During the year 1889 the output of gold has increased by over 56,000oz. as compared with that of the previous year, the total being 737,800oz. Of this amount 125,500oz., 112,700oz., and 51,000oz. came from Rockhampton, Gympie, and Croydon respectively.—During the past season 39,000 tons of sugar were produced in Queensland. This is very much less than might be produced in so suitable and extensive a soil as there is in that colony, but the difficulties as regards labour are no doubt a great drawback.—In the northern districts of Queensland some of the farmers and landowners are forming themselves into a company for carrying on the manufacture of extract of beef. An extract of beef which is made in a country where there is no great supply of old cab and 'bus horses ought to be generally acceptable.

COTTON SPINNING COMPANIES.

Though the margin between yarn and cotton is at the moment very poor—in fact, little more than change for a shilling—the several cotton spinning companies which took stock last Saturday have declared large profits. Subjoined is a list:—

	Spindles.	Profit.	Dividend.
Duchess	73,012	£1,543	10 per cent.
Lower Moor	9,756	286	10 „
Central.....	50,000	1,700	10 „
Higginshaw.....	91,600	900	—
Woodstock	81,876	608	—
Star	103,536	1,890	10 „
Commercial..	62,894	1,256	—
Gladstone	84,588	1,953	—
Arkwright	73,000	2,641	15 „
Crawford.....	154 464	4,998	10 „

The above results represent the margin at the beginning of the year, when cotton was ⅛d. per lb. lower than to-day, and when also the margin was very remunerative. Since then several things have gone against spinners. Not only has cotton advanced in price, but the yarn demand has slackened—that is, the consumption of both cop-twist and weft has fallen off, for looms have stopped, owing to the prolonged deadness of the cloth markets for India. Looking forward to the March quarter, the spinning companies will show larger profits than usual. The public should, however, bear in mind that business at the moment is difficult to transact, and the encouraging prospects of Christmas are gone to the winds. The whole position of the cotton trade is abnormal. The stock of cotton in Liverpool is over a million bales, and yet with small sales daily prices do not decline.

VINE DISEASES IN AUSTRALASIA.

According to the latest reports of the Vine Diseases Board of New South Wales, it appears that the phylloxera has been almost stamped out in that colony. The board have examined nearly a thousand vineyards, and they find that the disease is confined to three districts principally—viz., Camden, Sevenhills, and Toongabbie. They have, accordingly, entirely destroyed about twenty vineyards, roots and all, at a cost of about £7,500, which is to be paid by the Governments of South Australia, Victoria, and New South Wales. There is quite a scare in New Zealand about the phylloxera, and it appears that it is decidedly in evidence. The Government, however, is doing its best to see what steps can be taken, and, if possible, the same course will be adopted as has been pursued with such success by New South Wales.

A NEW FIRM OF ELECTRICAL CONTRACTORS.

The present time is a favourable one for the commencement of a business in electrical engineering and contracting, so that the new firm, Messrs. Girdlestone, Tatham, & Co., of 16 Davies Street, Berkeley Square, London, W., has undoubtedly a promising future before it. Mr. Girdlestone has for some time been chief engineer to Messrs. B. Verity & Sons, King Street, Covent Garden, and our readers will remember that he was the joint winner with Mr. F.V. Andersen of the "*Industries* Electromotor Prize." The new firm will make a specialty of electric light and ventilating installations, and in the near future they intend to commence the manufacture of certain electrical apparatus.

LEAD POISONING BY PATENT STOPPERS.

Mr. D. Woodman has recently issued a warning against the use of the patent combination rubber and metal stopper which is now being so generally employed for closing bottles of beer, soda-water, and other carbonated beverages. It appears that a number of cases of lead poisoning in the hospitals of Newark, New Jersey, were produced through patients drinking beverages from bottles stoppered in this way. The alloy used contains 46 per cent. of lead, the other metal being tin. More tin than lead appeared to be dissolved in the liquids, but the symptoms of poisoning noticed seemed to be due to lead. From the attention called to the subject in America many of the leading manufacturers have substituted ordinary corks and rubber stoppers for the patented one complained of.

VAN STEENBERGH WATER GAS.

Professor Lewes has recently furnished a brief report on the experiments which have been in progress for some time past at Knightsbridge to demonstrate the advantages of the Van Steenbergh process of manufacture of water gas. The inventors of the process claim that by the process it is possible to make 22 candle gas by employing naphtha for carburetting the water gas at about 1s. 2d. per 1,000 cubic feet, which is considerably more economical than the results which have been obtained in America by the older water-gas systems. Prof. Lewes has found, however, that the plant erected at Knightsbridge is capable of producing 1,000 cubic feet of gas having an illuminating power of 20·5 candles from a consumption of 24·5lb. of Welsh anthracite coal and 2·75 gallons of naphtha of 70° Beaumé, which, practically, confirms the claims of the inventors. With gas coke and naphtha of 40° B. similar results have been obtained, Prof. Lewes stating that 3,900 cubic feet of gas, having an illuminating power of 22·1 candles, were produced from 250lb. of gas coke and 13·5 gallons of naphtha. The percentage of carbonic oxide in the carburetted gas is below 25 per cent., and it is comparatively free from sulphur, which makes it still more advantageous to the consumer than coal gas. Apparently gas can be manufactured on this system with much less labour and less space than that required in ordinary gas works.

Patent Record.

(Compiled from "The Illustrated Official Journal (Patents)."

APPLICATIONS FOR PATENTS.

(The names in italics within parentheses are those of Communicators of Inventions.)

ENGINEERING.

17th February, 1890.

2510. Cocker, B. F. ..... Drawn swell ended wires for gun parts.
2511. Fiechter, E. ..... Machinery for sifting flour (*Fiechter*).
2514. Tetlow, Tetlow, & Taylor ..... Winding yarns.
2515. Campbell, A. ..... Disengaging gear for ships' boats.
2519. Meldrum & Meldrum ... Furnaces.
2521. Elliot, J. G. ..... Pumps.
2522. Haggart, T. ..... Machine tools.
2523. Jerram, F. O. ..... Sewing machines.
2528. Toovey, A. F. ..... Low water alarms for steam boilers (*Kildoyle*).
2529. Whitley, A. A. ..... Machines for stretching woven fabrics.
2534. Oldfield, B. ..... Machines for cleaning streets.
2536. Thomerson, C. ..... Sheet metal roofing.
2537. Speight, A. G. ..... Machine for the manufacture of corrugated paper or other textile fabrics.
2540. Martin, W. H. ..... Ventilating stoke holds.
2542. Bird, F. ..... Sewer ventilation columns.
2543. Warnant-Créon, J. ..... Magazine firearms.
2544. Chenhall, J. W. ..... Smelting furnaces.
2545. Gutmann, J. ..... Tool-holding chuck.
2548. Hilditch, H. ..... Drilling tools.
2549. Morris, R. ..... Magazine firearms.

18th February, 1890.

2566. Allison, H. J. ..... Rock drills (*Rand & Githens*).
2568. Marshall, W. H. ..... Railway trucks. (28th August, 1889.)
2569. Dovey, J. ..... Tube-lined wells.
2576. Cooper, E. W. ..... Lubricating bearings.
2581. Smith, J. ..... Marine boilers.
2582. Moss & Moss ..... Looms.
2585. Hudlestone & Willans Permanent way for railways.
2587. Fielding, J. ..... Gas engines.
2589. Holgate & Holgate ..... Looms.
2607. Fraser, J. ..... Multiplying and controlling gear.
2612. Grocock, W. A. ..... Closing doors of lift wells.
2614. Brooks & Barlow ..... Ring spinning machinery.
2618. Haddan, H. J. ..... Charging furnaces (*Wellman*).
2622. Bittinger, H. ..... Apparatus for conveying pulverulent materials.
2627. Boult, A. J. ..... Sole sewing machines (*Bertrand & Bray*).
2629. Thompson, W. P. ..... Producing car wheels (*Barr*).
2632. Thompson, W. P. ..... Centrifugal filtering apparatus (*Stehlik*).
2634. Dixon, T. S. E. ..... Air brakes. (22nd July, 1889.)
2637. Heymann & Prosser ... Car couplings.
2638. Hill, T. ..... Spring pedestal bearings.
2639. Fisher, T. W. ..... Pipe wrenches.
2642. Wells, C. ..... Hot-air engines.
2644. Lake, H. H. ..... Fire alarm apparatus (*Automatic Fire Alarm and Extinguisher Company, Limited*).
2647. Lake, H. H. ..... Gas engines (*Beckfeld & Schmid*).
2648. Lake, H. H. ..... Air engines (*Schmid & Beckfeld*).
2649. Summerton, T., Jun., & Brown ..... Steam engines.
2652. Michales, M. A. ..... Mining machines.

19th February, 1890.

2657. Waddington, E. ..... Overhead travelling crane.
2663. Smith, L. H. ..... Sewing machines.
2665. Britten & Biddlecombe Uniting rods or tubes.
2667. Gray, J. G. ..... Safety cage for mines.
2670. Campbell, H. ..... Gas engines.
2675. Wilson, A. ..... Spinning yarns.
2677. Robertson, E. J. ..... Grain elevator.
2680. Parkinson & Parkinson Ventilating apparatus.
2681. Brining & Lister ..... Machinery for lasting boots.
2683. Thompson, W. P. ..... Heating and purifying feed water (*Sutcliffe*).
2686. Bown & Capewell ..... Machines for shearing wool.
2691. Brown & Sutcliffe ..... Engine governor.
2695. Haddan, H. J. ..... Ventilating (*Mossner*).
2700-1. Newton, A. V. ..... Projectiles (*Nobel*).
2703. Dales, J. H. ..... Steam engines.
2704. Cito & Funck ..... Lifting jack.
2707. Whipple, C. A. ..... Machines for the manufacture of textile fabrics.
2708. White & Hill ..... Sheet metal boats.
2709. Pitt, S. ..... Diminishing recoil of firearms (*De Nottbeck*).
2712. Horne & Whinfield ... Breechloading guns.
2715. Cooper & Wigzell ..... Apparatus for taking soundings.
2719. Behringer, A. ..... Pulverising machines.

20th February, 1890.

2722. Smith, W. E. ..... Aëronautic apparatus (*Parloff*).
2728. Murday, T. J. ..... Gas engines.
2730. Robinson & Henderson Rollers made from slag.
2733. Harrison, W. ..... Knitting machines.
2734. Fairweather, W. ..... Fringing machines.
2736. Cliffe, W. ..... Woollen condensers.
2740. Wood & Whitaker ..... Boiler furnaces.
2743. Oldershaw, H. A. ..... Sewing machines.
2744. Servus, F. ..... Type-writing machines.
2756. Thame & Sanguinetti ... Machinery for the manufacture of hollow ware.
2757. Holman, E. A. ..... Breakwaters (*Holman*).
2758. Serraillier & Armstrong ..... Self-centreing chuck.
2760. Allport, S. B. ..... Drop-down small arms.
2763. Wise, W. L ..... Apparatus for dyeing textile fibres (*Mommer*).
2765. Cail, R. ..... Projectiles.
2767. Lock, C. ..... Railway brakes.
2770. Eli, A. J. ..... Sewing machines (*Welch*).
2771. Hughes, F. ..... Double-thread sewing machines (*Welch*).
2774. Imray, J. ..... Centrifugal machines (*La Société Nouvelle des Raffineries de Sucre de St. Louis*).
2778. Pidot, H. ..... Rotary fans.

21st February, 1890.

2782. Allison, H. J. ..... Typewriting machines (*Hamilton*).
2784. Brindle, Reade, & Taylor ..... Distributing sand on railways.
2787. Seddon, E. ..... Apparatus for sand-papering wood.
2789. Wilson, H. J. ..... Economising fuel.
2791. Merington, C. ..... Shell for rifled ordnance.
2799. Young, R. ..... Railway couplers.
2800. Leeming & Wilkinson ... Looms.
2803. Smith, H. ..... Apparatus for sifting grain.
2804. Dixon & Dack ..... Water-tube steam generators.
2807. Mortimer, Mortimer, & Wright ..... Looms.
2809. Hall, J. ..... Looms (*Lockwood*).
2810. Humphrey, J. T. ..... Pipe wrenches.
2811. Prince, F. O'C. ..... Gas pumps (*Parker*).
2818. Kiefer, G. ..... Dust collector and steam trap.
2821. Crowley, R. J. ..... Night signalling apparatus.
2822. Crowley, R. J. ..... Marine signalling system (26th August, 1889).
2826. Wauters, G. ..... Propelling boats.
2830. Brighton, W. H. ..... Drop-down small arms.
2835. Vavasseur, J. ..... Mounting guns.
2837. Dyson, J. E. ..... Hank dyeing machinery.
2839. Hopkinson & Hopkinson Water gauges.

22nd February, 1890.

2848. Eyre, G. F. ..... Apparatus for packing cotton wool.
2849. Spencer, G. ..... Haulage rollers.
2850. Stott, J. H. ..... Sectional warping and beaming machines
2851. Firth, G. H. ..... Differential regulation for steam engines.
2852. Bungeroth, W. G. ..... Rotary motors.
2863. Black, J. B. ..... Scutching machines.
2866. Whitehead & Mason ... Gas and hot air engines.
2867. Gessner, E., Jun. ..... Cloth shearing machinery.
2868-9. Boult, A. J. ..... Pneumatic guns (*Eichbaum*).
2870. Thompson, W. P. ..... Apparatus for cutting sugar canes (*Maurin*).
2872. Newton, J. M. ..... Steam boilers.
2874. Lees & Jones ..... Locomotive blast.
2875. Martin & Hendrickx ... Sewing machines.
2887. Schnarrendorf, J. F. A. Feed water purifiers.
2889. Fletcher & McFarlane Rivet-making machines.
2890. Wise, W. L. ..... Tools and tool-holders for machine tools (*Berger*).
2892. Horn, W. W. ..... Tacking machines (*Dean*).
2893. Brown, A. ..... Triple-expansion steam engines.
2897. Horn, W. W. ..... Lasting machines (*Dean*).
2900. Bawden, P. ..... Machinery for the manufacture of bricks and tiles.
2901. Jones, F. J. ..... Copper tubes, cylinders, &c.
2902. Ingraham, W. W. ..... Machines for grading grain.
2904. Lake, H. H. ..... Tool-holders for machine tools (*Garnier & Weil*).

ELECTRICITY.

17th February, 1890.

2527. Cornwell, O. ..... Electric arc lamps.

18th February, 1890.

2621. Watel, H. G. ..... Electrically driven fans.
2653. De Ferranti, S. Z. ..... Electric meters.
2654. Kingsbury, J. E. ..... Electric cables (*Western Electric Company*).
2655. Kingsbury, J. E. ..... Insulating electric wires (*Western Electric Company*).

19th February, 1890.

2659. Parsons, C. A. ..... Search light projectors.
2660. Scott, R. A. ..... Incandescence electric lamps.
2687. Armstrong, A. W. ..... Producing electricity.
2688. Armstrong, A. W. ..... Electric wire running.
2716. Brewer, W. J. ..... Electrical tramcars.

20th February, 1890.

2759. Timmis, I. A. ..... Lighting trains by electricity.

21st February, 1890.

2819. Lütcke, C., Jun. ..... Solution for batteries.
2825. White, W. ..... Electrical fuses, switches, &c.
2843. Braun & Lloyd ..... Telephonic receiver.
2844. Atkinson, L. B. ..... Continuous current armatures.
2845. Mackrill, E. T. ..... Secondary batteries.

22nd February, 1890.

2876. Walter, H. E. ..... Safety apparatus for preventing danger from high tension electric currents.
2905. Horn, T. ..... Electric indicator for revolving speeds.

CHEMISTRY.

17th February, 1890.

2526. The Borax Company, Ld. Manufacture of borax. (2nd October, 1889.)
2533. Thompson, C. ..... Recovery of metal from scrap.
2547. Johnson, J. Y. ..... Gunpowder (*Pieper*).
2559. Maxim & Sedgwick ..... Carburetting gas.

18th February, 1890.

2633. Leith, J. ..... Treatment of alkali waste.

20th February, 1890.

2772. Mayer & Lorrain ..... Recovery of gold.

21st February, 1890.

2808. Noad, W. ..... White lead.

22nd February, 1890.

2864. Young, W. ..... Paraffin wax.

MISCELLANEOUS.

17th February, 1890.

2539. Dennys, N. B. ..... Anti-fouling compositions for ships' bottoms.

18th February, 1890.

2609. Rogers, C. D. ..... Screw nails.
2611. Popplewell, W. W. ..... Artificial fuel (*Conried*).
2617. Hade, T. ..... Fire escape.

19th February, 1890.

2661. Edward John Shaw & Co. Hurricane lanterns.
2682. Sloan & Bell ..... Anti-fouling compositions.
2710. Harris, I. B. ..... Indiarubber valves.
2714. Hothersall, W. ..... Shuttles.

20th February, 1890.

2732. Hewitt, F. J. ..... Fog signalling.
2746. Moseley, A. ..... Compressed block fuel.
2769. Schlund, H. A. ..... Percussion fuses.

21st February, 1890.

2827. Boult, A. J. ..... Treatment of textile fabrics.
2832. Applegarth, E. ..... Treatment of straw, esparto grass, &c.

22nd February, 1890.

2896. Joy, W. ..... Cement.

COMPLETE SPECIFICATIONS ACCEPTED.

Notice is given that all persons interested in opposing the grant of a Patent on any one of the under-mentioned Applications may, at any time within Two Months after the date given, give notice at the Patent Office, in the prescribed form, of such opposition.

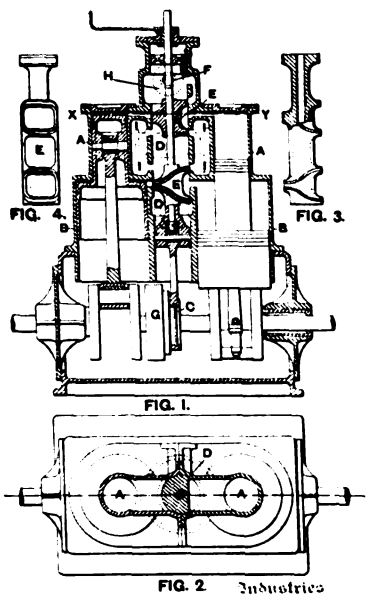
ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.

ENGINEERING.

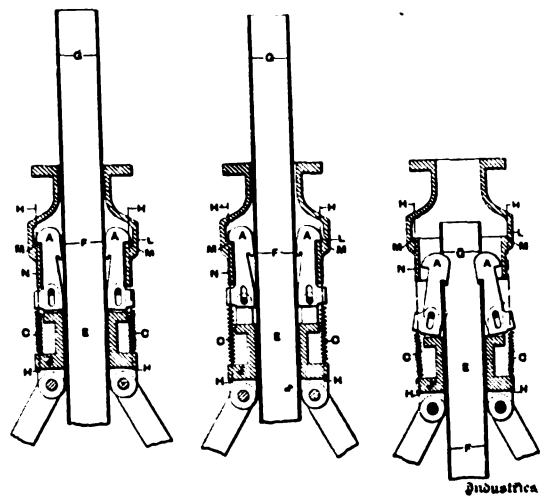
Screws for Furnace Feeding.—*T. Andrews, Sheffield.*—The screws instead of being made solid as are usual is made according to the present invention hollow. In casting a screw a longitudinal hole of any desired length and diameter is made up the centre of the screw. The hole is opened at least at one end to admit a blast of air, steam, or gaseous fuel, which passes along the hole and out into the furnace and fuel through small holes or apertures. The stem of the screw may be made of increasing diameter with the helical blades decreasing proportionally to slightly disturb and break up the green coal; or, the stem may be made in sections of varying diameters for a similar purpose. The blast of air passed into the furnace through the hollow screws assists combustion over the screw case. Four claims are made. —No. 4904. March 21st, 1889. 8*d*.



Propeller Shafts.—*C. D. Abel, London.* (*Gas Motoren Fabrik, Deutz, Germany.*)—For the purpose of reversing the rotation of the propeller shaft, the shaft is arranged in line with the motor shaft, and the two shafts are connected directly together for the forward motion by a conical friction clutch. The fixed part of the clutch is upon the driven shaft, whilst the sliding part is upon the motor shaft. A second similar clutch is arranged upon the motor shaft, the sliding part working upon a feather, whilst the other is fitted loosely upon the shaft and carries a toothed ring. A third friction clutch is arranged upon the driven shaft, with its parts arranged similarly to the second clutch upon the motor shaft and carrying also a similar gear ring. The gear rings of the second and third clutches are geared together by two wheels upon a counter shaft parallel to the propeller shaft. The whole of the clutches are worked together by a single lever, so that as the first clutch disconnects the motor shaft from the propeller shaft the second and third clutches simultaneously fix their gear rings to their respective shafts, and the motion of the motor shaft is transmitted through them and the counter shaft to the propeller shaft in a reversed direction. The cones of the first and second clutches being both upon the motor shaft may be combined into a double truncated cone shape to simplify the arrangement. One claim is made for the arrangement as described.—No. 5616. April 2nd, 1889. 8*d*.

Sand Blast Apparatus.—*J. E. Mathewson, Sheffield.*—In this apparatus a jet of steam is used to propel the cutting material. Fig. 1 is a sectional elevation of the appliance, and Fig. 2 is a plan. The steam is admitted from any convenient supply by the pipe C, and passes through helical passages D in the drying chamber B to give it a rotary motion. The rotary motion causes the steam to throw off by centrifugal force any moisture held by it. The steam passes up through the nozzle E to the pipe and funnel F, carrying with it sand, which trickles through the pipes G from the chamber above to the dish H. As the sand and

FIG. 2.
FIG. 1.
Industries.



steam emerge from the funnel F the steam is drawn off by a steam jet exhauster I, and the sand passes on and strikes the glass being operated upon. A valve J is constructed to adjust or stop the supply of sand by turning the handle K from side to side. Claims: (1) In a sand blast apparatus in which steam is the motor, a blast pipe, as L, having its open lower end entering a dish-shaped hopper supported by or placed immediately above the steam jet E, such hopper being supplied with sand, in regulated quantities, by gravitation, direct from the dry sand chamber, as set forth, whereby the liability of the sand to come in contact with moisture from the condensed steam is avoided; (2) the arrangement of sand blast apparatus as described, in which the receptacle for the condensed steam, and the mud arising from the pulverisation of the sand, and of the surface under treatment, is placed below the dry sand chamber and its connections.—No. 14,923. September 21st, 1889. 8*d*.

Steam Engines.—*W. Wilson, Lowestoft.*—In the engine described in this specification the cylinders are arranged side by side, and a specially designed slide valve works in a circular chamber between them. The slide valve and its ports are so constructed that by a partial rotation of the valve the engine is reversed. Fig. 1 is a vertical section upon the engine, Fig. 2 a sectional plan upon the line X Y, and Figs. 3 and 4 a front and side elevation of the slide valve cast in one piece. The engine is constructed with high-pressure cylinders A and low-pressure cylinders B; between these cylinders is a circular chamber D for the slide valve E. The slide is connected to the crank shaft by an eccentric C and Hartnell type of governor G. In the longitudinal sections the slide valve E is of a Y form at the parts which control the admission of steam to opposite cylinders. To reverse the engine the valve is turned half round on its axis by a joint

FIG. 4.
FIG. 3.
FIG. 1.
FIG. 2
Industries.

forming the connection between the valve and eccentric rod. In working the engine, steam is admitted by the pipe F to the top chamber H, and passed alternately to the high-pressure cylinders A. From the high-pressure cylinders the steam is exhausted to the chamber I, and from there passed to the low-pressure cylinders. Claims: (1) A steam engine in which cylinders are arranged side by side or facing one another with their axes parallel, with an intervening valve chamber having oppositely arranged ports leading to the respective cylinders, and a piston valve or valves having or each having a single web on one side and double webs on the other side, the arrangement and operation of the valve or valves being substantially as described; (2) a steam engine of the kind referred to in the preceding claim wherein the reciprocating distributing valve or valves is or are made capable also of movement in a rotary sense so that the engine can be reversed by turning the valve or valves; (3) a steam engine in which cylinders are arranged side by side or facing one another with their axes parallel with an intervening valve chamber having ports leading to the respective cylinders, those leading to the cylinders at one side of the valve chamber being at different points in the length of that chamber from those leading to the cylinders at the other side, and a piston valve or valves having cavities at opposite sides thereof with working faces, the arrangement and operation being as described; (4) in an engine of the kind referred to in the preceding claim, providing between the valve or valves and the eccentric that actuates the same an adjustable connection whereby the distance between the eccentric and the valve or valves can be readily altered and the engine be thereby reversed as described. —No. 2148. February 6th, 1889. 8*d*.

Excavator Grabs.—*S. M. Cockburn, London.*—The object of this invention is to produce an automatic clip gear for grab buckets. The form of construction of the appliance preferably used is shown in the accompanying illustrations, which are sections upon the same parts in the different positions they assume whilst in use. Commencing with the grab being raised from the ground shut, the top part of the hooks A strike against the bottom corner of the suspender L; the hooks are pressed thereby into the openings F F in the frame E. When they come to the shoulder M they fly out, by the action of the springs C C, and the position of the parts in Fig. 1 are obtained. The grab is now lowered, the hooks resting on the shoulder, and on account of the action of the springs having no tendency to slip off the shoulder. Lowering continues, and the whole and every part of the grab, with the exception of the hooks, move downwards until the pins rest in the bottom of the slots, the parts at this instant assuming the positions shown in Fig. 2, in which it will be seen that the openings F have moved downwards and past the head of the hooks, which cannot now slip off the shoulder. The downward movement of the crosshead J is now arrested, and much of the weight of the grab is resting on the hooks A A; the line of action H H of this load gives the hooks a tendency to slip off the shoulder M, as the load is much greater than the force acting in the line of action of the springs, but the slipping is at

Industries.

present prevented by the frame of the grab. Lowering still continues, the frame E moving downwards and the grab opening. When the opening G in the frame passes the hooks they immediately slip from the shoulder M, and are instantly pulled downwards by the springs and are locked in gear with the frame, the part N of the suspender preventing their flying out of the openings while the hooks are falling. Fig. 3 shows this position the instant of falling from the suspender. As soon as the crane chain arrests the face of the grab, the pins will travel down the slot and rest on the bottom, and the grab will be suspended in the air open. Claims: (1) An apparatus constructed substantially as described and for the purpose set forth, whereby a hook so loaded that, when rested on a shoulder, it has no tendency to slip off, may be given a tendency to slip off by a change in the line of action of the load on the hook; (2) the combination of a hook with a limited amount of movement, with a spring or its equivalent, whereby the hook is made to engage instantly with the frame of the grab when released from a shoulder on the suspender; (3) the combination of a slot in a hook with the particular position of an opening in the frame, whereby the opening may move its position in such a manner that the hook cannot slip into it by the time it is given a tendency to slip from the shoulder on which it was resting; (4) the portion N of the suspender whereby the hooks are prevented from disengaging from the frame E until they have had time to become locked in position.—No. 3616. March 1st, 1889. 8*d*.

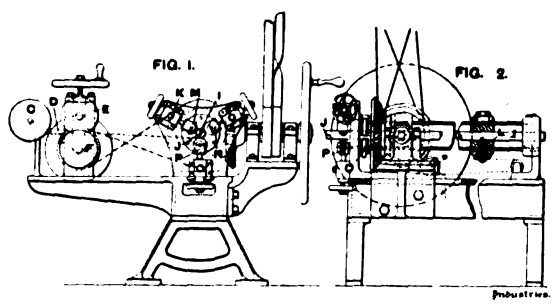
Nut-Locks.—*N. B. Dennys, Malay Native States, Malay Peninsula.*—The nut-lock consists of a thin disc of soft metal, preferably of copper, with a centre hole to fit the size of bolt to which it is to be applied. The periphery of the disc extends wholly or partially beyond the corners of the nut. On one surface of the "washer" thus formed a stud is riveted, or a projection punched, which enters a hole or depression of similar size in the surface to which the nut is applied. When the disc is in place and the nut screwed home a projecting part of the disc is either cut or turned up, so that the portion so treated prevents the nut from turning. Claim: The formation of an indentation in, or application of a stud to, an ordinary thin soft metal washer, or to a washer having a projecting lag, which indentation or stud is intended to enter an indentation made in the surface to which it is applied, the outer edge or lag of the said washer (as the case may be) being free to be turned up against any face of the nut screwed down over it, so as to lock the said nut rigidly in its place.—No. 1962. February 4th, 1889. 6*d*.

Digitized by Google

FLANGING AND SHAPING METAL PLATES.—*A. C. A. Holzapfel, London.*—The machine here described is specially applicable to flanging and shaping shipbuilding plates. It consists of a powerful press whose dies are constructed of a number of metal rods of suitable length and of ¼in. to 1in. square. The ends of the rods constitute the surface of the dies. The rods are placed on end and are surrounded by a heavy steel hoop, with which the bars can be clamped in any position side by side. To give the dies the curved surface required a pattern of the plate is laid underneath the rods, the hoop slackened, and the rods allowed to fall and rest upon the pattern; the hoop surrounding them is then tightened. A similar proceeding is adopted in forming the other die. When both dies have the shape of the pattern, a thin asbestos plate is laid on the lower portion, and the plate to be shaped, after being suitably heated, is laid on the top. This is again covered with an asbestos plate, and the upper die is pressed upon the plate by mechanical means until it has assumed the shape required. Claim: The principle of using rods with roughened sides in a heavy iron band as means by which heavy iron plates can be simultaneously flanged and shaped, and which principle admits of the machine being adapted for any shape or form.—No. 2377. February 11th, 1889. *6d.*

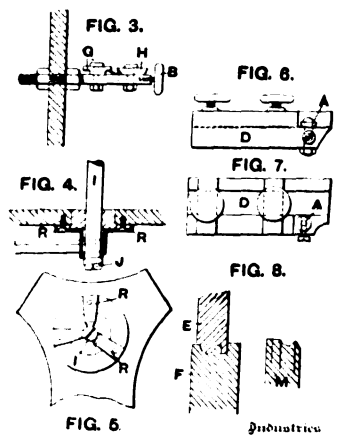
COAL SCREENING AND BREAKING APPARATUS.—*H. Simon, Manchester.*—This invention relates to an arrangement of apparatus employed for the screening and breaking of coal preparatory to washing. The trucks conveying the crude coal are run on to a tipping stage, and are there tipped, and their contents delivered unto a slightly sloping oscillating screen. The smaller fragments fall through the meshes of the screen into the washing pit, and the larger pieces are delivered over the lower end of the screen on to a shoot, from which they pass to a stone breaker. From the stone breaker the crushed coal drops into the washing pit, and from the washing pit the washed coal is raised by an elevator to be further dealt with if necessary, or to be delivered into trucks for transport. Claim: The combination of a tipping platform, an oscillating screen and shoot and a stone breaker, as described.—No. 2699. February 15th, 1889. *6d.*

WINDING AND DRAWING MACHINES FOR SILK.—*A. Ridgway, Macclesfield.*—An improvement is here described in connection with the spindles of these machines. The spindles are surrounded by a series of springs, which are made from sheet steel or other suitable material. The sheet steel is cut or slotted to form the springs, and the ends are left intact to bend round the spindle and form ferrules. One end of the spring is fixed to the spindle, whilst the other remains loose to permit the requisite amount of play for the working of the springs. The springs by thus being made in one piece act concentrically and keep the bobbin running truly on the spindle. The springs may be made with one or more ferrules in the middle. Claims: (1) Making or forming a series of springs in one part or piece, as and for the purpose described; (2) the making or forming two or more series of springs in the length of the spindle in one piece or part, as and for the purpose described.—No. 1432 January 26th 1889. *6d.*



CRUSHING ORES.—*W. H. Coward, Bath.*—Improvements are here introduced into the apparatus described in a former specification, 12895 of 1888. The apparatus consists of a revolving drum, containing an edge runner rolling freely within the drum. The drum is provided with suitable means for supplying and removing the ore undergoing treatment. The improvements introduced are: First, to steady the edge runner so as to keep it central between the sides of the drum; secondly, to enable the roller to be variably weighted; thirdly, to facilitate driving the apparatus. The runner is kept central between the sides of the drum by being secured to a shaft which passes out through the opening in the side of the drum used for feeding purposes. The shaft is supported in two bearings, one of which is fixed, and the other (nearest to the runner) made to rise and fall, but weighted down by a lever and weight. The weight is made adjustable upon the lever, to permit variable pressure being brought upon the runner. The drum is partially supported by a tubular shaft concentric with the drum's axis and supported horizontally in bearings. This tubular shafting opens into the drum and constitutes the outlet for the pulverised material. To reduce the friction in the revolution of the drum, and to assist the hollow shaft in supporting the drum, the drum is made to roll upon rollers. Four claims are made for the improvements described.—No. 5286. March 27th, 1889. *6d.*

DRYING COTTON, &c.—*C. Turner, Rochdale.*—This invention refers to a method and apparatus for drying cotton, wool, and such like material when in the form of hanks, the material having undergone the process of dyeing, sizing, or similar process. Hitherto the hanks have been dried by being placed upon fixed staves or rails, as is well known, and have occupied much time in drying; with this improved apparatus motion is given to the hanks and in consequence they are more quickly dried. The apparatus has a hollow shaft supported vertically in a frame. To the top of the shaft is secured a belt pulley for the purpose of revolving the shaft upon its axis. The shaft also supports two drying frames which are arranged in a plane at right angles to the shaft. The top frame is fixed to the shaft, but the lower frame is made to slide upon it and is adjustable. The hanks are stretched from rails on the top frame to corresponding rails on the lower frame, the lower rails being adjusted to suit the lengths of the hanks. Motion is then imparted to the shaft by the belt pulley and the frames made to revolve with the hanks in the extended condition described. Claims: (1) In a machine for drying hanks of fibrous material, the employment of a spindle or shaft provided with a fixed frame and sliding frame, each carrying rails, the sliding frame acting as a means for stretching or distending the hanks. Two other claims are made for the apparatus as illustrated in the specification.—No. 4850. March 20th, 1889. *8d.*



CORLISS STEAM VALVES.—*R. Middleton, Leeds.*—In this specification is described a small appliance for indicating the exact proportion of the stroke at which the steam is being cut off from the cylinder of an engine in motion. On the valve spindles, or on any suitable rocking shafts connected with them, is arranged a pointer which travels along the face of a plate. On the plate is marked a scale which represents the points of the stroke in divisions of one-hundreths. The pointer fixed to the rocking shafts travels along the plate until the steam is "cut off," when it returns quickly to its normal position. In some cases use is made of an additional registering pointer which is pushed along by the rocking pointer and stands at the maximum "cut off." The registering pointer may be made to be moved back to zero by slow driving gear or moved back by hand. Claims: (1) The application to an engine fitted with tripping gear on its steam valves of recording dials with indicating pointers—worked directly or indirectly off the steam-valve-spindles—for the purpose of showing the point of the "cut off"; (2) the apparatus in the whole or part as and for the purpose described.—No. 4067. March 8th, 1889. *8d.*

SCREW CUTTING TURRET HEADS.—*P. M. Justice, London.* (*J. M. Becher, Mishawaka, U.S.A.*).—The turret or die carrier is composed of two concentric discs placed one above the other. The dies are arranged radially around these discs in the edges of their peripheries, which face each other. The discs are made to open and close towards each other by an eccentric or cam motion operated by a hand lever. The discs are supported upon a hollow mandril, and can be revolved about their axis, so that any of the dies may be readily brought into action. The bolt to be screwed is preferably rotated, and the turret head slid up to it, but the turret head itself may be revolved and the work held stationary. Thirteen claims are made.—No. 15083. September 24th, 1889. *8d.*

MACHINERY FOR MAKING FLEXIBLE METALLIC COVERING.—*F. E. Plumb, Leeds.*—The flexible metallic covering is used for belts, bracelets, straps, dog collars, &c. The machinery produces spirally wound tubular casing from a continuous metal strip. The casing is afterwards flattened by means of suitable dies in a screw or hydraulic press. The metallic strip of metal is wound upon the bobbin C; from there it passes through a guide

D (Figs. 1, 6, and 7), which turns up one edge. From D it passes between the rollers E and F (Figs. 1 and 8), which give it a shape approximating its final shape. Having passed between the rollers E and F, the metal strip is led through another pair of dies G H, Fig. 3, which gives it its final shape, approximately that of an S, before being spirally wound. It is next attached by the slot J to the mandril I (Figs. 1, 2, and 3). The mandril I slides within a second mandril, but revolves with it, as a pin L passes through a slot in the outer mandril and is screwed into the mandril I. The outer mandril is geared by mitre wheels to the driving pulleys. The metal strip having been attached to the mandril I, the mandril is revolved, and the strip spirally wound upon it. As the strip is wound upon I, three dies, M N and P, interlock, and finally close the edge of one turn in the edge of the following. Claims: (1) In apparatus for producing spirally wound tubular casing the means of regulating and setting the finishing dies M N P; (2) in apparatus for producing spirally wound tubular casing, the employment of friction wheels O for the purpose of minimising the tensile strain upon the metal or composition strip during the finishing operation of spirally winding and closing; (3) flattening between suitable dies in a screw or hydraulic press spirally wound tubular casing to form a covering for belts, bracelets, dog and other collars, and harness ornaments; (4) in apparatus for producing spirally wound

tubular casing, the employment of the segmental collar R with internal projections to perform the office of a guiding nut to the metal strip as it passes to the dies M N and P; (5) in apparatus for producing spirally wound tubular casing, the employment of the set screw S for regulating the position of the primary shaping wheel A; (6) in apparatus for producing spirally wound tubular casing, placing the final shaping dies G H upon a bed to support the metal or composition strip and confine it within these dies which determine its final shape according to the relative position of the dies governed by the set screw B.—No. 1390. January 25th, 1889. *8d.*

RAILWAY SWITCHES.—*L. B. Stevens, London, & A. H. Johnson, New Jersey.*—The object of this invention is the better adjustment of switches in cases where more than one pair are actuated by one lever. This is done according to this invention by equalising the pressure given to each of the switches against the stock rails. The appliance for equalising the pressure is fixed in any convenient part of the rod connections between the lever locking apparatus and the switches. It consists of a cross-bar, which is pivoted at its centre to the rod leading from the operating switch. To the extremities of the arms of this cross-bar are pivoted the rods leading to the switches. With this arrangement when the switches are worked, if the tongues of one pair of switches strike the stock rails first, the lever rod, if pushed farther, continues to operate through the cross-bar the other switch rod until the pressure on the two switch rods are equal and the tongues of each switch pressed with equal force against the stock rails. If the rod leading to one switch should be a direct continuation of the rod leading from the operating lever, the end of the switch rod may be made hollow to receive the reduced end of the lever rod, and so form a lengthening and shortening joint whilst supporting the ends of the rods. The switch rod and the lever rod are in this case connected by a connecting rod. If one switch rod branches off from the direction of the lever rod, it may be connected to the lever rod by a bell crank lever and connecting rod. Instead of using a cross-bar, as described, the ends of the switch rods may be in the form of racks, and a pinion supported at the end of the lever rod to gear with the two, but free to revolve about its axis.—No. 5514. April 1st, 1889. *8d.*

CONVERTING RECIPROCAL INTO CIRCULAR MOTION.—*H. M. Lucas, Birmingham.*—Upon two parallel shafts are supported, free to revolve, two sector gear wheels with teeth around half their circumferences. Fixed to the shafts are clutches which engage with and lock the sector-geared wheels to the shaft at one point only. Two other gear wheels are also fixed to the shafts and connected by a chain which receives the continual rotary motion in one direction. Between the toothed surfaces of the gear wheels first mentioned works a double-toothed rack. The rack receives the reciprocal motion and imparts to the sector-geared wheels a backward and forward rotary motion of half a turn. As a consequence, one of the sector-geared wheels has, in the forward motion of the rack, the same direction of revolution as the other wheel has upon the backward motion of the rack. The clutches are therefore made to gear with one sector wheel in the forward movement of the rack and with the other wheel in the backward movement. Instead of using a double-toothed rack and sector-geared wheels, flexible bands may be employed and attached to smooth-surface wheels and to a bar working backwards and forwards between the two wheels. Claim: Mechanism for converting reciprocating motion into circular motion arranged and operating as described.—No. 5467. March 30th, 1889. 8d.

PURIFYING FEED WATER.—*J. Donaldson, Chiswick, London.*—According to this invention, the removal of impurities such as compounds of lime and magnesia from feed water is conducted in a steam generator as illustrated. Fig. 1 is a sectional end view, and Fig. 2 a sectional side view. The steam generator is of the type described in the specification No. 1404 of 1885. A is a horizontal cylindrical steam collector and separator fitted with a baffle

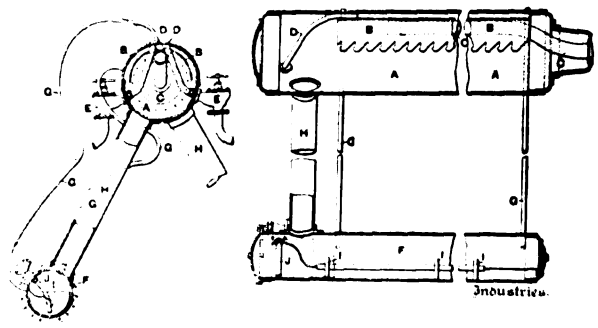


plate B, steam outlet pipe C situated under the baffle plate B, and inlet pipes D supplying feed water to be purified. The feed water supply is controlled by the valves E, and delivered on to the top of the baffle plate. The steam collector A communicates by the pipes G and H to water vessels F. With the construction described, when the feed water is turned on whilst the steam generator is under steam, the water will be directed by the inlet pipes D upon the baffle plate, where it will be intimately mixed with, and heated to a high temperature by, the steam that will also be discharged upon the baffle plate by the pipes G. The feed water, with its impurities thus rendered insoluble, will flow over the baffle plate to the bottom of the steam collector, and thence by the pipes H to the water vessels F, wherein the impurities will be deposited, whilst the steam escapes through the pipe C. The impurities may be blown off by pipes such as J, or collected in boxes placed in the water vessels under the pipes H and removed bodily. Zinc blocks I are placed in the water vessels to prevent corrosion, and assist in separating the impurities by acting as baffle plates. Claims: (1) For purifying feed water, the combination of a baffle plate, a feed water inlet or inlets arranged to discharge feed water above such baffle plate, an inlet or inlets for steam (or steam and hot water) to act upon the feed water above the baffle plate, these several parts being arranged in a suitable vessel connected with a second vessel through which the feed water that has been acted upon as aforesaid can pass and wherein any impurities rendered insoluble by the action of the steam or steam and hot water can deposit; (2) in a steam generator of the kind hereinabove referred to, admitting the feed water above the baffle plate in such a manner as to cause it to be there acted upon and purified by the entering jets or streams of steam or steam and hot water.—No. 4106. March 8th, 1889. *8d.*

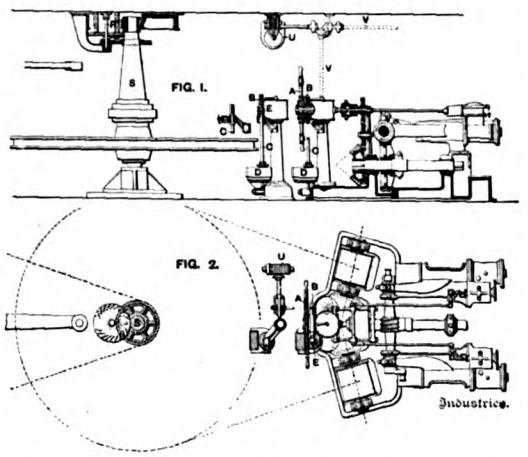

STEAM BOILERS.—*E. R. Joicey, Gateshead.*—This invention refers to the construction of the internal flues of boilers adaptable to boilers of the Lancashire and Cornish type. The flue has formed in it at intervals along its length two or more "mid-feathers" crossing at opposite angles and open at each end to the water in the boilers. These "mid-feathers" have a flattened elliptical cross-section, and are placed lengthwise in the flues. Between the flattened sides of the "mid-feathers" are inserted a number of tubes, through which the flames and gases from the furnace pass. The outside surfaces of the tubes are surrounded by water from the boiler. In order to make the flames and gases traverse the length of the flue in a serpentine or spiral direction, and to pass alternately over and under the "mid-feathers" and through the tubes, baffle bridges are provided made of refractory material. Claim: The construction of the internal flues of steam boilers with water mid-feathers at intervals along the length of flue, and crossing it in the manner of circulation tubes, said "mid-

Digitized by Google

feathers" having between their flat sides a number of fire tubes so arranged that by "baffle bridges" the flame and gases from the furnace are compelled to take a serpentine course through the flue, and so obviate the injurious effects of the upper portion of the flue only being traversed by the flame and gases as well as to increase the strength of flues to increase the efficiency of boiler.—No. 5382. March 29th, 1889. 8*d*.

ELECTRICITY.

ELECTRICALLY CONTROLLED STEAM STEERING GEAR.—*W. Clark, London.* (*Sigmund Schuckert & Co., Nürnberg, Germany.*)—The object of the invention is to control steam steering machines by means of an electromotor, and to replace the mechanical connections heretofore employed between the captain's bridge and the steering gear. Figs. 1 and 2 show a steering engine on Macfarlane Gray's system with the present invention applied. To the hand wheel A there is attached a small worm wheel B, with which engages a worm E on the armature shaft C of an electromotor D. To enable the engine to be worked by hand when required, the worm E is made to be disconnected from the shaft C of the armature. The electromotor D, and consequently the steam steering engine, is caused to rotate in the one or other direction by the operation of a hand lever of a switch situated on the bridge, and

to which are connected wires of a dynamo machine used to light the ship. This switch is shown in Figs. 3 and 4. F and G are the leads to the ship's dynamo. H is the lever, which is held in its normal position, as shown, by springs I J. When this lever is moved, the ends of the springs K L come into contact with the fixed contacts M and N or O and M. From these contacts wires lead to the brushes of the electromotor D, so that the steering gear is operated by the movement of the lever H. An electric rudder telegraph P indicates at all times the position of the rudder. The hand of the telegraph is operated by two pairs of solenoids Q electrified by a succession of contacts made by an arm upon the spindle R (Fig. 1) which is geared to the main shaft S. A device is constructed to prevent the electromotor working any farther in

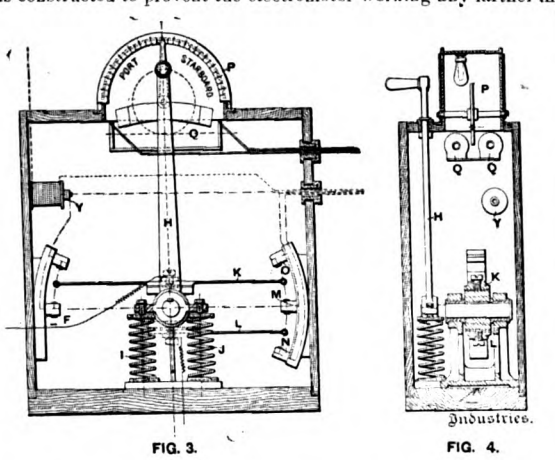

FIG. 3. FIG. 4.

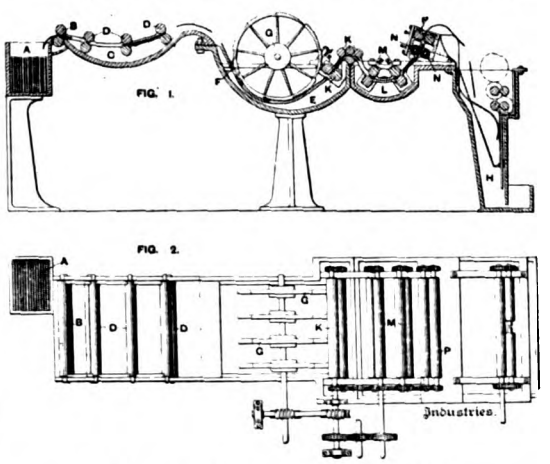
the same direction when the rudder is hard over, notwithstanding that the hand lever H is kept hard over. Claims: (1) In electrically controlled steam steering gear, the arrangement of an electromotor D acting on the starting valve of the steam steering gear as described, in combination with a switch arranged on the bridge (preferably included in the electric light lead of the ship) and an electric lead connecting this switch with the said motor, which is normally without current, but by the motion of the switch lever either way from its central position receives a current flowing in the one or other direction, and is caused to rotate and effect a movement of the starting valve in the corresponding direction; (2) the substitution, in lieu of the motor D referred to in claim 1, of an electromotor U which is movably coupled with the shafting V that connects the hand steering wheel on the bridge with the apparatus on the steering engine; (3) the arrangement of a contact device Y in the lead to the armature or to the magnet coils of the electromotor D (or U as the case may be), in combination with an electromagnet (or solenoids) which when brought into circuit on the rudder reaching either of its extreme positions breaks the contact at Y and thus prevents further rotation of the electromotor.—No. 17914. November 9th, 1889. 8*d*.

CONDUITS FOR ELECTRIC CONDUCTORS.—*F. King, London.*—The conduit is constructed of earthenware troughs, made in convenient lengths and jointed together in the manner of drain pipes. The troughs may be covered by earthenware or iron lids. Holes are provided in the sides of the troughs for the connection of other troughs for carrying the leading-in wires to premises, &c. The insulated cables for the high tension charging current are carried by brackets formed upon each side of the troughs. The bare or insulated copper bars for the purpose of supplying the low tension current are carried by oil or other suitable insulators fixed to bridges spanning the bottom of the trough. These bridges are provided to permit any water that becomes condensed to pass under them and not come into contact with the insulators fixed on the top of the bridges. The water flowing through the conduits may be carried off at various points to the street drains. Claim: A conduit or support for underground electric conductors, the said conduit or support being constructed or arranged as described.—No. 5433. March 29th, 1889. 6*d*.

HARDENING STEEL TUBES.—*W. L. Wise, London.* (*M. Kramer, Berlin.*)—To overcome the difficulties usually experienced in hardening internally tubes of small diameter, the inventor makes use of electricity for heating purposes in the following method: The tube to be hardened is connected to a vessel filled with water, cold air, or carbonic acid, or other liquid or gaseous cooling substances under considerable pressure. Between the tube and the vessel is provided a cock, that enables communication with the interior of the vessel to be opened and closed as required. On the tube to be hardened, near to each of its ends, is placed a collar or clamp; each of these are in electrical connection with one pole of an electric battery or other source of electricity. The hardening is effected by passing through the tube an electric current of sufficient strength to heat the tube to the temperature suitable for hardening. The current is then quickly interrupted, and the cock opened to admit a current of cold liquid or gas to flow through the tube. In this way uniform hardening of the interior of the tube is effected. Claim: The hereinbefore described method of internally hardening steel tubes of any diameter, the said method consisting in heating the tube by the passage through it of an electric current, and then suddenly cooling it by a suitable liquid or fluid, delivered under pressure, from a reservoir to which the tube is connected, the electric current being previously broken or shunted as described.—No. 13659. August 29th, 1889. 6*d*.



CHEMISTRY.

AMMONIUM CALCIUM PHOSPHATE.—*G. A. H. Gabet, Paris.*—The object of the invention is to manufacture a new manure—viz., ammonium calcium phosphate. For fixing the ammonia obtained by the distillation of urine or dung water, the inventor makes use of a concentrated acid solution of phosphate of lime, instead of sulphuric acid as is usual. A shallow cylindrical enamelled iron vessel is employed to receive the phosphate solution. This vessel is hermetically closed by a cover, and to its side is connected the pipe for conveying the ammoniacal gas from the distilling apparatus. The cover is provided with an agitator serving to mix the solution. Claims: (1) The employment of a solution of acid phosphate of lime for fixing ammonia to be used as manure, such application producing a product composed wholly of lime, nitrogen, and phosphoric acid, and of exceptional richness in the two latter substances; (2) the new product obtained as described in the preceding claim.—No. 5340. March 28, 1889. 6*d*.

COPPER AND ITS ALLOYS.—*G. G. Mullins, Los Angeles, U.S.A.*—The object of this invention is to refine copper and to render it more fusible. The copper is treated with a flux which is composed of purest native silica, fluor spar, carbonate of potash, and tungstate of sodium. These elements are first carefully crushed to a fine powder, and then all carefully compounded together in about the proportions of four parts of silica, three parts of fluor spar, two parts of carbonate potash, and one part of tungstate of sodium. On the bottom of the crucible, or on the bed of a reverberatory furnace, is placed from 1 to 10 per cent. of the mixture according to the character and weight of metal charged; when all is molten the bath is thoroughly stirred and allowed to remain quiet for a few moments. The scoria or dross is skimmed off, or 1 to 10 per cent. of the mixture, carried in paper bags, may be placed into the already molten metal. Claims: (1) The improvement in the process of cleaning, refining, and purifying copper and its alloys, which consists in adding to the metal a mixture of silica, fluor spar, carbonate of potash, and tungstate of sodium, in about the proportions set forth, commingling them by melting, skimming off the dross, and then proceeding in the usual manner; (2) the mixture of silica, fluor spar, carbonate of potash, and tungstate of sodium, in substantially the proportions set forth, to be used to cleanse, refine, and improve copper and its alloys.—No. 16,649. 1889. 4d.

ALUMINIUM.—*R. E. Green, London.*—This invention relates to the production of aluminium from the double fluorides of aluminium and sodium or potassium. The process is carried out in a suitable crucible which has an inlet at its extreme lowest part. Over this inlet are placed broken bits of charcoal, coke, or other refractory substance to prevent its being stopped up by the subsequent operations. Upon this charcoal is placed the fluoride of aluminium and sodium or potassium which has been mixed with silica, silicate of soda or potash, or other compound of silicon and finely powdered charcoal, and the whole is covered by a layer of newly-burnt lime. The mouth of the retort is closed with the exception of a small opening, and the retort is heated with its charge to a red heat. The retort is kept in this heated state for one hour, and during that time coal or other hydrocarbon gases are admitted through the small opening at the bottom. At the end of this time the decomposition of the fluoride is completed, and the gas is turned off and the slag removed. When the whole has been allowed to cool it will be found that the greater part of the aluminium is mixed with and absorbed by the charcoal and coke at the bottom of the retort, and can be separated therefrom by the ordinary methods. Good proportions are as follows:—Double fluoride of aluminium and sodium, 112lb.; silica (white sand), 48lb.: charcoal, finely ground, 28lb.; lime (freshly burnt), 38lb. Claims: (1) The production of aluminium in the manner as described; (2) in the production of aluminium from fluorides of aluminium and double fluorides of aluminium, and sodium or potassium, and the using of silica or silicates of soda or potash, or other compounds of silicon.—No. 5,914. April 6th, 1889. 4*d*.

COATING METAL SHEETS WITH TIN.—*E. Lones, Lydney, R. Davies, Lydbrook, J. Davies, Lydney, & B. A. Webb, Lydney, Gloucestershire.*—This machinery is designed to reduce the manual labour that is at the present time employed in the process of coating metal sheets with other metal. In the accompanying illustrations are shown (Fig. 1) a longitudinal sectional elevation and (Fig. 2) a plan of the machinery. The plate or sheet to be coated is taken from the water bath A and passed between the india-rubber covered rolls B to remove the water from it. It is next passed between a series of wooden rolls D in the

grease trough C, and led to the coating pot E. As it enters the coating pot it is held between corrugated shaped guides F, from which it is taken by the notches of the wheel G and conveyed through the pot as shown. The edge of one plate is made to overlap that of the preceding plate, to keep it in the notch. The plate is taken out of the coating pot and conveyed to the dipping pot L by a series of rollers, K and M; from these it passes between the brushes N supplied with oil. The plate is drawn through the brushes N by metal rollers P, which pass it on to the cradle O of an ordinary double grease pot H. It is afterwards finished in the usual manner. Claim: The method of and apparatus for coating metal plates or sheets with tin and other metals substantially as hereinbefore described and shown in the figures.—No. 4003. March 7th, 1889. 8*d*.

EXPLOSIVE COMPOUNDS.—*E. Liebert, Berlin.*—The inventor describes a new method of mixture for nitro-glycerine and dynamite in order to reduce their sensitiveness to blows and shocks without reducing their explosive force, and also to lower the temperature at which they congeal. Isoamylnitrate is the substance employed, and when added to nitro-glycerine presents all the advantages enumerated above. If 5 per cent. of isoamylnitrate be added to the nitro-glycerine the freezing point of the mixture is reduced to 35 degrees below zero, whilst its sensitiveness to blows or shocks is much less than that of pure nitro-glycerine. The isoamylnitrate is also completely decomposed by the explosion of the nitro-glycerine, and the gases produced scarcely differ from those produced by the explosion of pure nitro-glycerine. A suitable addition of isoamylnitrate is 3 per cent. In lieu of adding isoamylnitrate to the prepared nitro-glycerine an emulsion of glycerine and isoamylnitrate may be nitrated. Claims: (1) The improved process of preparing nitro-glycerine, which consists in adding isoamylnitrate to nitro-glycerine; (2) the improved process of preparing nitro-glycerine, which consists in nitrating a mixture of glycerine with isoamylnitrate or isoamylalcohol.—No. 5503. March 30th, 1889. 4*d*.

MISCELLANEOUS.

LINING BARRELS TO RESIST ACIDS.—*T. Bell, Lincoln.*—In order to overcome the well-known difficulties in providing acid-proof linings to barrels and other vessels used in the chlorination process of extracting metals, the following method has been devised:—The vessel is made of any suitable material, such as steel or iron, of the requisite strength, and into it is placed a lining composed of—firstly, a layer of lead, which may or may not be in metallic union with the vessel; secondly, a layer of gutta-percha, or similar substance, impervious to acids, which substance is by heat caused to unite with the lead; thirdly, a second covering of lead united to the gutta-percha by the same means as the first. As a modification, the gutta-percha may by heat be cemented directly to the barrel, and then a coating or covering of lead can be applied on or to the gutta-percha to constitute the lining. Claim: Lining barrels or other vessels with lead and gutta-percha, as above described, to resist acids for use in extracting metals by chlorination, or similar process, from their ores.—No. 2350. February 9th, 1889. 4*d*.

AIR VALVE.—*J. B. Dunlop, Belfast.*—This device consists of a short tube of caoutchouc or other elastic material, which is inserted and projects a short distance into the interior of the expansible article to be filled with compressed air. Within the inner end of this tube is placed a plug or short rod of hard india-rubber or vulcanite. The plug is cemented to part of the inner surface of the tube and constitutes the valve. The action of the device is as follows:—When air under pressure is forced into the article to be inflated, the elastic tube expands and permits the air to pass between the uncemented surfaces of the plug and india-rubber tube. When the pressure ceases, the elastic tube contracts and tightly embraces the plug or valve, the contraction being assisted by the pressure of air in the inflated article. Claim: The improved non-return air valve described.—No. 4115. March 8th, 1889. 6*d*.

Copies of the British specifications may be obtained on application to H. READER LACK, Esq., *Comptroller-General, Patent Office, Southampton Buildings, London, W.C. The published price must be remitted, together with a sum sufficient to cover postage, which may be reckoned at* ½*d. for every* 10*d. or fraction of* 10*d. Remittances exceeding one shilling must be made by Post Office Order.*

CARRIAGE WHEEL MAKING MACHINE.

The machine which we illustrate herewith has recently been made by Messrs. John Sutcliffe & Son, wood working machinists, &c., New Bank, Halifax, for a firm of carriage makers in America. This machine is characterised by its durability and strength, and by the variety of operations which can be conducted by unskilled hands. The centre holes of the naves are bored and the spokes bored and mortised. The spoke ends are tanged for the felloes after they are driven into the nave and the felloes are bored to suit the tang. Any other boring and mortising work required in carriage building can also be done upon it.

THE RECENT GROWTH OF TECHNICAL SOCIETIES.

II.

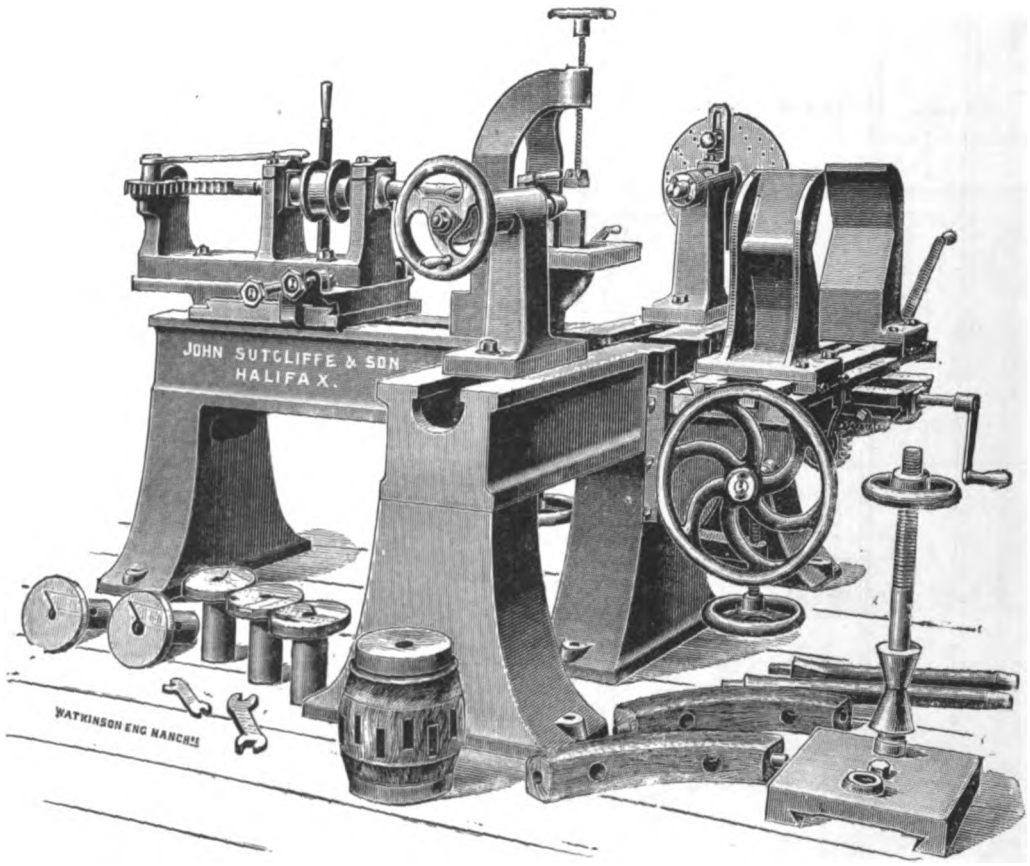
In a recent article on the scientific work of the year 1889, the *Times* justly observed that "to examine, sift, and estimate all that science has said and done in a year would require a society of specialists in itself, working day by day, all the year round." Some such conclusion must have struck everyone who has taken the slightest trouble to inquire into the growth of scientific societies within recent years, and the work that they have accomplished. There is not, unfortunately, any exact record of the numbers, names, characteristics, and membership of the societies that are carried on outside of the United Kingdom. An attempt to formulate such a list was made in the first annual issue of the Year-Book of the Learned Societies—a most useful work, which gives particulars of all the scientific associations carried on in the United Kingdom, and the titles of the papers read at each from year to year. The work of collating the particulars relative to British societies has, however, apparently been found sufficient for one year-book, so that the foreign societies are in danger of being overlooked or neglected in any attempt to estimate the development of this great movement and its results on the intelligence, industry, and progress of the present day. Not to speak of Germany, France, Italy, Austria-Hungary, and Scandinavia, which are apparently as rich in learned societies as the United Kingdom, we find that in the United States every different State or Territory has its own series of scientific bodies, while such cities as Philadelphia compare most favourably with any similar town in England in the number, variety, and importance of the bodies that carry on the good work. So also in South and Central America. Mexico, for example, has its societies for the advancement of medicine, of geography, of natural history, of statistics, and of mineralogy. In Buenos Ayres, again, we find the Academy of Sciences, the Societies of Entomology and Palæontology, the Geographical Society, the *Sociedad Cientifica Argentina*, &c. Our Australian Colonies, including New Zealand and Tasmania, have a good and increasing show of the same kind, and neither China, Japan, nor our Indian Empire are behind, while even Java can boast of six different bodies, established with the same end in view.

A statement was compiled by the late Professor Levi which included an interesting comparison of the numbers of members of the different societies representing the different departments of science as between 1867 and 1878. The Professor found that the number of members in each group of societies showed the following extent of progress or retrogression over that period:—

	Number of Members in 1867.	1878.	Percentage of Inc.	Dec.
Royal Societies of London and Edinburgh, and Royal Irish Academy	1,359	1,305	—	3·97
Societies representing the Physical and Mathematical Societies	3,616	5,406	49	—
Societies representing Biology and Natural History	16,186	16,534	2	—
Societies representing Archæology and Geography.....	3,930	5,038	28	—
Societies representing Applied Sciences	14,506	21,949	51	—

The last-named group, which, of course, included the Institution of Civil Engineers, the Institution of Mechanical Engineers, the Iron and Steel Institute, the Institution of Naval Architects, &c., has, as might be expected, made by far the greatest progress. The fact is that while such societies as those representing biology, natural history, archæology, &c., are carried on for the pure love of science by enthusiasts who are more or less hobbyists, if not also faddists, the sociology of applied science is a necessary part of professional training and connection, with but few exceptions. And the societies that have most closely held this ideal up before them have approached most nearly to the position of becoming an almost indispensable trades union. The Institution of Civil Engineers, for example, have increased their membership from 1,698 in 1867, to 4,739 in 1888, being an increase of about 180 per cent. in about twenty-two years. It has been the same, though not to such an extent, with such societies as the Institution of Mechanical Engineers and the Iron and Steel Institute, which provide pabulum in the form of papers and discussions which are of such solid and substantial advantage to the interests that they represent that they may be almost immediately turned to commercial advantage by the discerning and capable.

The arrangements of scientific bodies differ very much in the matter of the frequency of their meetings. The famous French Academy of Sciences, for example, meets every Monday throughout the year, while our own Royal Society only meets weekly during a session of six months. The Institution of Civil Engineers holds a regular meeting every Tuesday during the winter session, and occasional students' meetings besides, but the Institution of Mechanical Engineers only meets four times in the year, and either one or two of these meetings is held in the provinces or abroad. Others, again, like the Chemical Society, which meets on the first and third Thursdays of the session between November and June, meet only fortnightly, while a hybrid society like the Society of Arts finds sufficient materials to hold usually two or three different meetings (including the sections during the week) while the session lasts. Finally, there are societies, like the Institution of Naval Architects and the Iron and Steel Institute, which meet only twice a year or so, holding, however, their meetings during several days, so that they get over almost as much ground as the societies that meet weekly or monthly. The British Association is almost the only one that holds an annual gathering only.



Most of the learned societies have laid themselves out for the collection and arrangement of a library representing the special branches of knowledge that they were established to cultivate. The principal, and especially the older, bodies, have in this way secured libraries of great value, that are the habitual resorts and the indispensable aids and accessories of specialists. Thus, the Royal Society has a library of about 43,000 vols.; the Royal Institution, a library of 45,000 vols.; the Royal Society of Edinburgh, a library of 15,500 vols.; the Pharmaceutical, a library of 9,000 vols.; the Geographical, a library of over 20,000 vols., the Geological, some 17,500 vols.; the Civil Engineers, more than 20,000 vols.; the Mechanical Engineers, about 4,000 vols.; and so with many other bodies. In the constitution of many learned societies, "the formation of a library" is distinctly set out as one of the principal objects of their foundation, and by the majority of them this end has been kept steadily and successfully in view. The library of his society has become to the scientific man, or to the man who follows a professional career, whether chemistry, medicine, architecture, engineering, or some other, a necessary adjunct, and often an everyday resort.

The largest and, in many respects, the most important of the various societies representing applied and mechanical science in the metropolis is the Institution of Civil Engineers. The progress of this Institution is almost unique. Unlike the Royal Society, it has owed nothing to the favour of the State, or to the influence of the great ones of the earth. It has been a purely voluntary creation, and furnishes, perhaps, as good an example as it would be possible to furnish of the successful results of combination for a useful purpose. The Institution was established in 1818, and in 1828 it was incorporated by Royal Charter. The objects of the Society are stated to be "the general advancement of mechanical science, and more particularly for promoting the acquisition of that species of knowledge which constitutes the profession of a civil (*i.e.*, civilian) engineer." The standard of membership is so high that the position of a member is prized among the profession. In order to be eligible for membership a candidate must have been "regularly educated as a civil engineer, and have had subsequent employment for at least five years in responsible situations, as resident engineer or otherwise, of adequately important works." This phraseology, although it may seem to be fairly precise, is in reality such as to leave many loopholes for the admission of members whose claims are by no means high.

The Institution of Civil Engineers took forty-four years to reach a membership of 1,000. It took sixteen years to reach a membership of 200. The last twenty years, however, have seen the ranks of the Institution more than doubled, the present number of members and associates of all classes being upwards of 5,000. These figures are fairly illustrative of the growth of the engineering profession during the same period. Up to 1860 the profession had made slow progress, but since that date it has advanced "by leaps and bounds." This, however, is not all. There were many active and prominent members of the profession in the early days of the Institution, who did not deem it necessary or desirable to join its ranks, besides which there was for a time a considerable amount of rivalry offered by another body, known as the Society of Engineers, founded in 1854, and still carried on, although long since left far

(For description see opposite page.)

behind by the parent society. The latter has by far the finest range of premises of any scientific body in the world, not even excepting the Royal Society. It has a unique engineering library; and its "Proceedings," of which four large volumes are published annually, at a cost of between £7,000 and £8,000, may be truly said to cover the whole field of applied science, either in the papers read and discussed, or in the papers accepted and selected but not read, or in the "Abstracts" from foreign sources. The annual statement of accounts presented on behalf of this Institution is so voluminous a document that it would take a much greater amount of space to summarise it than we can afford; but it may be remarked, in brief, that as "none but itself can be its parallel," this is the less necessary for purposes of comparison. The subscriptions to the Institution have increased during the last twenty years from £5,060 to £14,575, and the admission fees and life compositions from £514 to £3,841. With an income of close on £25,000 a year, the Civil Engineers have really a valuable estate to control, and, its administration is, on the whole, satisfactory.

One of the youngest of the societies representing mechanical science on the electrical side is the present Institution of Electrical Engineers, founded in 1871 by the late Sir William Siemens and others, as the Society of Telegraph Engineers and Electricians. The growth of this association, like the growth of the science that it represents, has been phenomenal. It was so much of an infant that in 1879, when Professor Levi drew up a paper on the scientific societies of the United Kingdom, it was not thought worthy, apparently, of a place among them. It was, at all events, not named by the learned Professor. The Institution has now close on 1,600 members in all parts of the world; it has a splendid collection of works relating to electricity and the allied sciences, called the Ronalds Library; it holds frequent meetings, at which all matters affecting the progress of electrical science are discussed, and it has not a few other claims to consideration and to the influence which it wields. The financial position of the society is indicated by the following statement of the income in 1878 and 1888:—

Items of Income.

	1878.	1888.
Entrance fees	£19 18 0	£165 18 0
Subscriptions	752 3 6	1,510 14 0
Life compositions	71 0 0	86 0 0
Sales of "Proceedings"	204 14 1	121 6 3
Total income	1,431 16 6	2,012 6 9

The annual subscriptions, it will be observed, have practically doubled since 1878, and this is the great test of a society's solvency and health. There has, however, been a falling off in the sales of "Proceedings," which is not easily explained, seeing that the annual volume issued by the society is more bulky and valuable than it has ever been, as it naturally would be, having regard to the much more varied applications of electricity. The expenditure of the society has kept pace with the increase of income, but not to a larger extent than the growing importance of the society would appear to justify, the chief items being as under:—

Items of Expenditure.

	1878.	1888.
Salaries	£129 7 7	£587 8 4
Rent	129 6 7	241 15 9
Printing, &c.	239 11 11	708 10 10
Meeting expenses	35 2 8	88 7 4
Total expenditure	794 1 2	2,025 14 7

The Iron and Steel Institute is a somewhat older society than the Institution of Electrical Engineers, having been constituted in the North of England in 1869, under the presidency of the Duke of Devonshire. This society has also made remarkable progress, the membership having advanced within the first ten years to nearly 1,000, and being now about 1,600. The Institute has a more cosmopolitan character than most others, having a large number of foreign members, and being in the habit of holding meetings at frequent intervals on foreign soil. The Institute publishes two large volumes of "Proceedings" annually, which contain abstracts of matters affecting the iron and steel industries from foreign sources. The income of the Institute, as between 1878 and 1888, has varied as under:—

Items of Income.

	1878.	1888.
Entrance fees	£170 2 0	£176 8 0
Subscriptions	1,850 2 0	2,648 2 0
Sales of "Proceedings"	86 6 3	194 2 3
Interest on investments	——	188 12 4

Here there seems to be progress all along the line, notably, however, in the members' subscriptions and in the sales

Digitized by Google

of "Proceedings." Like the Electrical Engineers, the Iron and Steel Institute publish their *Journal* through Messrs. Spon, the well-known scientific booksellers, thereby differing from the Institution of Mechanical Engineers and the Institution of Naval Architects, who only publish direct from the offices, as well as from the Institution of Civil Engineers, who only sell their "Proceedings" to members, and do not offer them to the general public at all. As will be noted from the following statement of expenditure, the outlay on behalf of the Iron and Steel Institute has not increased so much as that of some of the kindred societies between 1878 and 1888: –

Items of Expenditure.

	1878.	1888.
Salaries and wages	£637 6 6	£854 0 0
Office rent	87 0 0	333 13 6
Printing and illustrations	807 10 10	890 0 5
Meeting expenses	250 1 6	191 2 4
Other expenditure	196 17 0	146 11 11
Total expenses	1,978 15 10	2,415 8 2
Balance on the year	679 15 10	791 8 5
Amount invested at end of year	——	5,995 16 2

One of the most financially successful of the societies representing applied science is the Institution of Mechanical Engineers, which was founded at Birmingham in 1847, and had George Stephenson for its first president. For a great many years this Institution had its headquarters in Birmingham, where it was originally founded, but some thirteen years ago it was decided to remove it to London. The Institution had 572 members in 1867, 1,146 members in 1878, and over 1,800 members in 1888. During the last-named period its annual income has increased from £3,801 to £6,121, as the following statement shows:—

Items of Income.

	1878.	1888.
Current subscriptions	£3,110 0 0	£4,634 0 0
Ditto in arrear and advance	——	316 0 0
Entrance fees	201 0 0	263 0 0
Sale of "Proceedings"	69 2 4	93 18 0
Interest	419 1 2	814 4 3
Donation to library	2 2 0	——
Total income	3,801 5 6	6,121 2 3
Capital	12,116 4 9	26,409 18 0

The remarkable increase of capital owned by this society between 1878 and 1888 is due in some degree to its having been the fortunate recipient of bequests and donations, the most important of which was contributed under the will of the late Sir Joseph Whitworth, one of its Past-Presidents. The Institution has now reached the point when its annual income exceeds its expenditure by about £1,000 a year, more or less. The expenditure has varied as under between 1878 and 1888, which is a period almost coincident with the life of the Institution as a metropolitan institution:—

Items of Expenditure.

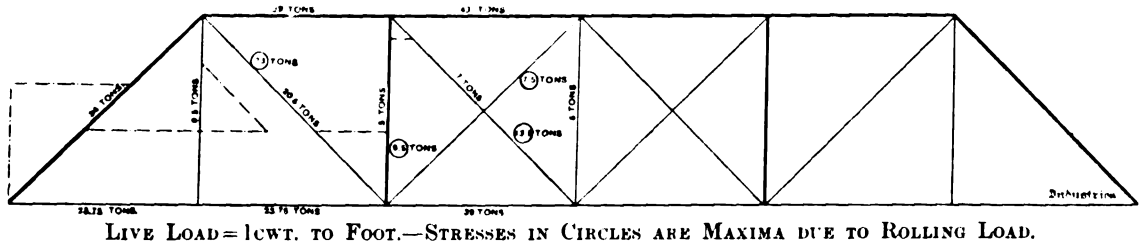
	1878.	1888.
Rent	£550 0 0	£550 0 0
Salaries, &c.	1,107 3 0	1,655 8 6
Printing, &c.	1,096 17 8	1,296 15 4
Meeting expenses, including travelling	430 12 10	535 4 5
Total	3,676 14 3	5,219 5 3

The expenditure for 1888, which would otherwise appear to be abnormally larger than in 1878, was swollen by an item of £490 11s. 3d. for "research" undertaken with a view to drawing up a standard system of marine steam engine trials, and by an item of £114 17s. 5d. for "dinner guests," showing that the Institution is not only intent on hospitality, but is not afraid or ashamed, by seeking to cloak this item under some other head where it would never be traced by members, of "letting its right hand know what its left hand doeth." The expenditure for printing in 1888 was also swollen by an item of £181 17s. 2d. for the revision and reprinting of the library catalogue.

One of the most important of the societies representing mechanical science in a country like our own, which depends so much upon its shipping trade and its naval supremacy, must necessarily be the Institution of Naval Architects, which was founded in 1860, "to promote the improvement of ships and all that specially appertains to them." If the measure of the labours of this society is to be the extent to which the shipping industry of England has grown since 1860, then it must be pronounced to have been very successful indeed. The tonnage of the British Register in that year was 4,586,000, as compared with about eight millions of tons at the present time, and the steam tonnage on the British register has in the same period advanced from 452,000 to nearly 5,000,000 tons. Again, in 1860 the tonnage of new shipping built in the United Kingdom was only 226,000 tons, whereas in 1889 it was nearly five times as much. Nevertheless, the Naval Architects are a comparatively limited, and perhaps exceptionally technical body, so that neither the membership nor the income of the society have grown, like those of some other bodies with a more extended area of operations. The income has varied as under:—

Items of Income.

	1878.	1888.
Subscriptions	£1,049 10 10	£1,807 0 6
Sales of "Proceedings"	92 13 6	161 10 11
Admiralty grant	250 0 0	250 0 0
Other receipts	264 0 0	——
Totals	£1,656 4 4	£2,218 11 5
Balance in hand	£266 13 8½	£1,294 11 11

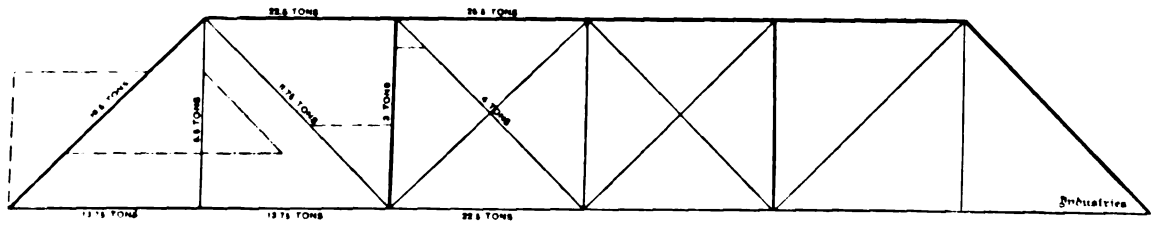


The Naval Architects have, after a long period of comparative impecuniosity and sailing near the wind, succeeded in obtaining a substantial balance to their credit. The actual income from members' subscriptions is less than that of any of the other societies occupying a leading position in mechanical science, but the membership, nevertheless, steadily increases, and now numbers between 700 and 800. As the following statement shows, the expenditure of the society has been kept within very favourable bounds, and in two items, at least, has actually diminished between 1878 and 1888:—

Items of Expenditure.

	1878.	1888.
Printing and illustrations	£652 9 10	£557 9 1
Salaries and wages	486 7 8	613 1 4
Meeting expenses	107 16 0	189 18 3
Rent	238 14 0	200 0 0
Other expenses	481 0 2	107 4 11½
Total expenditure	1,965 7 8	1,669 14 7½

A BRIDGE FOR CENTRAL AMERICA.



Diagrams of Stresses for 40 Metres Span.

Live Load = 1cwt. to Foot.—Stresses in Circles are Maxima due to Rolling Load.

Wind Load = 50lb. to Foot, Two Tons at Each Apex.—Diagram of Bottom Bracing.

Dead Load = 56lb. per Foot.—Superstructure and Flooring.

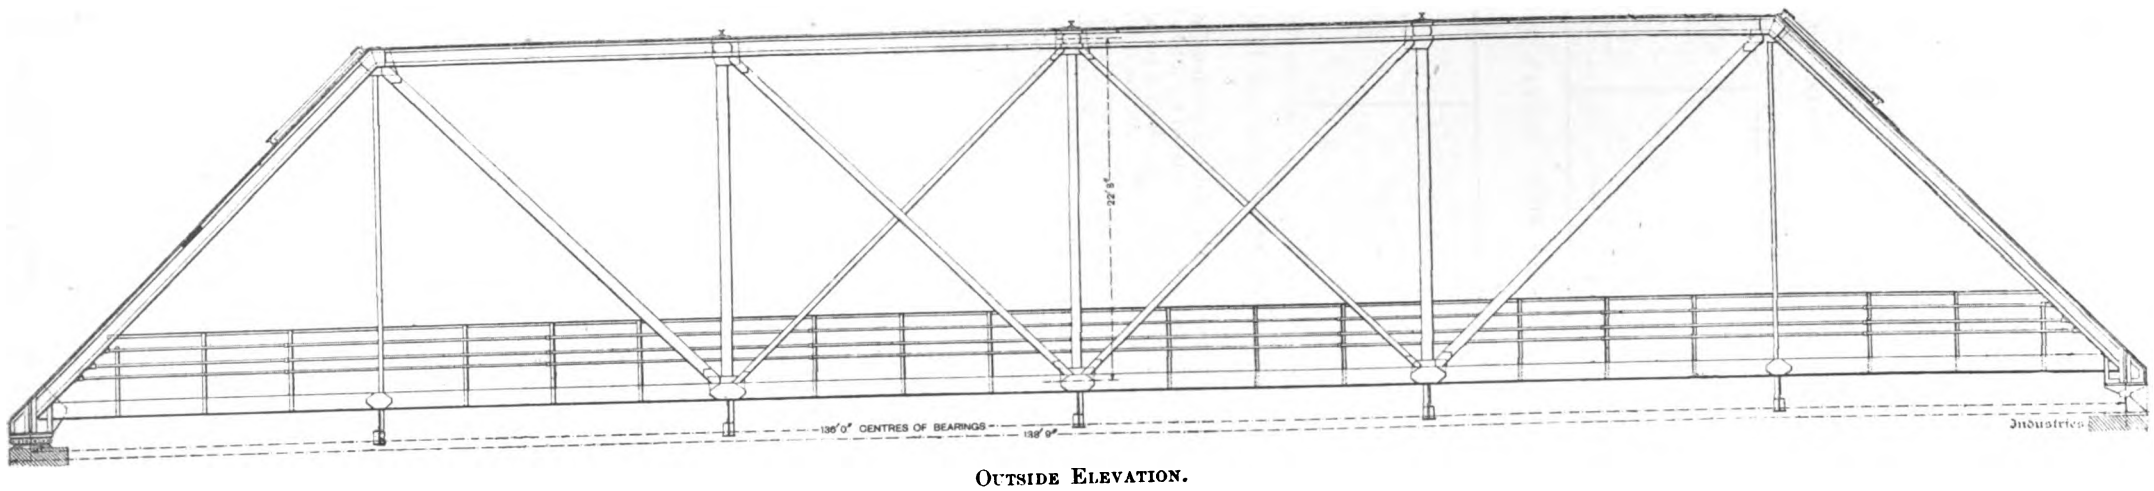
A BRIDGE FOR CENTRAL AMERICA.

The illustrations on pages 242 to 245 show a high-road bridge of 40 metres clear span that has recently been sent out to Central America. It has been designed by Mr. William Moore Angas, of Darlington, and built by the Darlington Wagon and Engineering Company. The general outline of the structure being different from the typical English design of bridge, a few words of explanation will be useful.

The bridge is intended to carry an ordinary high-road, and is calculated for a live load of 1 cwt. per square foot of deck area, which is certainly more than will ever come upon it. The stresses due to a live load of this density covering the entire structure are shown on the "live load" diagram above. The numbers in this same diagram in small circles are the stresses on certain members due to the most disadvantageous positions of the live load.

As the live load stresses are large in comparison with those due to the dead load, there is a considerable range of stress, and for this reason the various members are only lightly loaded. For example: The first main diagonal, consisting of two bars 8in. by $\frac{9}{16}$in., is stressed to only 4·3 tons per square inch of net area, and the other diagonals, in which the range of stress is greater, are not stressed to more than 3·8 tons per square inch.

The bottom boom is composed of two plates on edge. This member is nearly always in tension. Even when the bridge is unloaded, and when there is a wind pressure of 50lb. per square foot on the whole exposed area of both girders, there is only one panel of the bottom boom which is not in tension, and this panel is subjected to a total compression of only 2¼ tons, which is equivalent to 420lb. per square inch of gross area, on the iron plates composing the boom. These plates are, however, stiffened by diaphragms at intervals of 5ft. 8in., and are thus very efficiently stayed against compression, and may be safely relied on to transmit considerable compressive stresses. These bottom chord diaphragms carry posts for the handrail tubes as shown.



The various joints and connections to be made in the field are bolted instead of riveted. The bolts are all turned, and washers ¼in. thick are provided so as to give plenty of draw for tightening up the nuts without bringing the threaded portion of the bolts within the plates. The bolt holes were all drilled in position, whilst the complete girder was temporarily erected in the contractor's yard. All the plates through which any one bolt passes were drilled at the same operation. In this way very great accuracy is obtained, and the total load at any one joint is fairly distributed over all the bolts at that joint. Thus it is unnecessary to provide so large an excess of area in the cover plates and connections as is usual in riveted joints. The bolts are in double shear, and are stressed to not more than 3 tons per square inch; allowing nothing for their frictional grip, the iron behind them is loaded to about 6 tons per square inch of bearing area. The bottom system of wind bracing is composed of flat bars, but the upper system is of round rods tightened by right and left handed screws. Where these tension rods intersect there are small bolts in large oval holes, for the purpose of holding the two bars together and preventing rattling.

FOREIGN INDUSTRIES.

(From our own Correspondents.)

(FOR LATEST TELEGRAPHIC DESPATCHES SEE PAGE 249.)

PARIS, 11TH MARCH, 1890.

IRON.—A slack demand and weak prices are features which distinguish the iron market of the capital from those of the provinces. The Paris merchants are utterly wanting in unity of action, and, as they seek to win customers by underselling, prices have receded to 160s. for bars and 164s. for joists. These reductions have, however, failed utterly to tempt buyers out of their reserve. In the Haute Marne business continues active. The demand is strong for wire and wire nails, and founders report plenty of orders. For ironmongery, too, the market is animated. A moderately brisk current of business is reported from the Ardennes and the Nord. In the latter district prices are less firmly maintained.

THE PORT OF DUNKIRK.—The constant expansion of the trade of the port of Dunkirk is a circumstance favourable to French industry. The number of vessels entering in 1888 was 5,242, having an aggregate tonnage of 2,392,469. Last year the number was 5,071 vessels, representing a tonnage of 2,453,931, an aggregate that would have appeared larger had not the new regulations for gauging the tonnage come into force in the later months of 1889. The harbour improvements now approaching completion will tend to still further increase the trade of this port, and to make of it a formidable competitor with Antwerp.

FOREIGN TRADE.—The cry is everywhere for more protection. Each industry is confessing itself incapable of standing against foreign competition. Scarcely a day passes without some fresh fact, some new table of statistics being brought forward to prove the truth of this confession. What this signifies for the future of French industry we will not now attempt to divine; but it is instructive to examine some of these statistics which have reference to the relative developments of the export and import trade of this country. For example, the declared value of the manufactured goods was 1,428 million francs in 1860, and 1,556 millions in 1888. Absolutely considered this might be deemed a satisfactory degree of expansion, but relatively to the growth of the import trade in such goods it leaves much to be desired, for the value of these imports has increased from 124 millions in 1860, to upwards of 600 millions in 1888. It is clear from these figures that the economic conditions have materially changed, and that French industry is not holding its own against foreign competition. In the opinion of the vast majority of Frenchmen, the only remedy for this evil is to be sought in the system of protection.

BERLIN, 10TH MARCH, 1890.

ENGLISH COAL FOR THE PRUSSIAN RAILWAYS.—Two cargoes of English coal for consumption on the Hanoverian lines of railway have recently arrived at Bremen. The price paid is said to be 20s. a ton delivered on trucks. The fact that the State railway authorities are buying foreign coal shows that the supply of home produce is insufficient to meet current requirements. The imports of foreign coal are increasing.

PIG IRON PRODUCTION IN 1889.—The production of the German blast furnaces in 1889 was, according to the official returns just published, made up of 2,047,677 tons of forge and spiegel pig, 1,402,444 tons of Thomas pig, 405,490 tons of Bessemer pig, and 531,893 tons of foundry pig; the total was 4,387,504 tons, against 4,229,484 tons in the previous year, which shows an increase of 3·7 per cent. The increase would have been considerably greater had the supply of fuel not been interrupted by the strike in the coal mining industry. The total production in 1879 amounted to only 2,226,587 tons.

GERMAN IRON ABROAD.—The effects of high prices on the export trade in iron become more distinctly visible as old contracts run out. The total quantity of iron of all sorts sent out of the country in the first month of the present year amounted to 64,334 tons, against 70,846 tons in December and 90,235 tons in January of 1889. In the following classified list the figures within parentheses are those for the same month of last year: Pig iron, 8,632 (20,116) tons; old iron and scrap, 2,048 (2,062) tons; half wrought iron and steel, 1,505 (2,290) tons; finished iron and steel (in angles, bars, and plates), 14,947 (24,304) tons; wire, 9,609 (15,259) tons; wire nails, 3,131 (4,019) tons; rails, 8,581 (8021) tons; other railway iron, 4,717 (4,192) tons; heavy castings (except ordnance), 2,122 (1,237) tons; other manufactured goods (except machinery), 9,022 (8,732) tons; total, 64,334 (90,232) tons. The falling off is especially noticeable in pig, finished iron and steel, and wire. The shipments of wire and wire nails to Great Britain in January amounted to 3,327 tons for the former and to 984 tons for the latter. Japanese customers took 963 tons of wire nails.

THE GERMAN STARCH INDUSTRY.—From the report of the general meeting of starch manufacturers held here last week we learn that, with a potato crop of 21,000,000 cwt. Germany produced last year some 460,000 cwt. of starch, and Holland, with a potato yield of 500,000 cwt., produced 160,000 cwt. of starch. Professor Delbrück spoke of the use of potato starch mixed with rye or wheat meal for the manufacture of bread, and strongly recommended the practice, which he said was rapidly growing in public favour. A resolution was passed to make an appeal to the Government for a reduction of the railway rates of carriage for wet as well as for dry starch, to enable the German manufacturers to meet Dutch competition. The total exports of starch and potato meal in the first month of the current year amounted to 66,226 cwt., against 44,924 cwt. in the same month of last year. The principal customers are Great Britain and Spain. To the former the month's shipments amounted to 20,146 cwt., and to the latter 20,518 cwt.

NEW DOCKS ON THE RHINE.—It is proposed to build four large docks on the Hessian Rhine. One is to be built at Worms, and another at Bingen, a third near Oppenheim, and a fourth between Castel and Kostheim, in connection with the Main Canal.

THE INTERNATIONAL LABOUR CONFERENCE.—The following is the programme of the deliberations of the International Conference respecting the regulation of work in industrial establishments and mines:—I. *Regulation of Work in Mines.*—1. Shall the underground employment be prohibited: (*a*) of children below a certain age? (*b*) of females? 2. Shall a limitation of the hours of labour be provided for in mines wherein the work is particularly prejudicial to health? 3. Is it possible in the general interest to submit to an international regulation the work in collieries, so as to assure regularity in the output of coal? II. *Regulation of Sunday Work.*—1. Shall work on Sunday as a rule, and save in cases of necessity, be prohibited? 2. What exceptions may be allowed should such a prohibition be issued? 3. Shall such exceptions be determined by international convention, by Act of Parliament, or administratively? III. *Regulation of Child Labour.*—1. Shall children up to a certain age be excluded from industrial labour? 2. How is the age to be determined up to which the exclusion shall operate? The same in all branches of industries or differently? 3. What restrictions in the hours of labour and the kind of employment are to be provided in the case of children admissible for industrial labour? IV. *Regulation of the Work of Young Persons.*—1. Shall the industrial labour of youthful persons who have passed the age of childhood (12) be subject to restrictions?—2. Up to what age shall the restrictions take effect?—3. What restrictions are to be prescribed? 4. Shall exceptions to the general provisions be provided for in individual branches of industry? V. *Regulation of Female Labour.*—1. Shall the day or night work of married women be restricted? 2. Shall the industrial labour of all females (women and girls) be subjected to certain restrictions? 3. What restrictions are desirable? 4. Shall exceptions to the general provisions be provided for in individual branches of industry, and which? VI. *Execution of the Provisions that may be Agreed Upon.*—1. Shall measures be taken for the carrying out and supervision of the provisions to be agreed upon? 2. Shall repeated conferences be held of the representatives of the Governments taking part, and what tasks shall be assigned to them?

VIENNA, 10TH MARCH, 1890.

THE COAL MARKET.—The wintry weather which recommenced during the first days of this month has caused such a strong demand for coals in Vienna, that the Northern Railway will have its work set to supply all its customers. Special trains are fitted out to bring coals from the Ostrau district to Vienna. As the consumption is steadily increasing for both household and industrial sorts, the use of Bohemian brown coals will largely increase. The general manager of the State Railways has already commenced the calculation of special tariffs for the transport of Dux coals to the Vienna market. It is a question, however, whether the Bohemian works will be able to deliver all the necessary quantities, because the traffic in Bohemia is extraordinarily brisk. Last month the receipts of the Dux-Bodenbach Railway increased by 115,000fl., and those of the Prague-Dux Railway by 12,000fl., as compared with the same period of the last year. The Salgo-Tarjau coal works have issued the report for the last business year; it shows a clear profit of 432,000fl., and the company will pay a dividend of 16 per cent. At five of the Wolfsegg collieries near to Linz in Upper Austria a strike has broken out. Labourers demand an increase of wages and a reduction of the working time. Owners, however, are not willing to meet the claims of the labourers, and so the end of the strike is not to be expected.

THE IRON MARKET.—The iron market continues in the usual condition. The building season has already begun, and was followed at first by an increase of the demand for girders and rolled iron. Already the works have plenty of orders on hand. Bar iron has been raised 5fl. per ton in Bohemia. Machine makers cannot receive any further orders, and an import is being made from England in consequence. The Erste Brünner Maschinenfabriks-Actiengesellschaft of Brünn is enlarging its establishments, and a new machine manufactory is to be erected in the neighbourhood of that town. The Schick'sche foundry and machine manufactory of Budapest made a profit of 115,000fl. last year, and is paying a dividend of 12 per cent.

BRUSSELS, 11TH MARCH, 1890.

THE COAL MARKET.—The state of the coal market is becoming more regular. It will be remembered that at the commencement of the year the market experienced a succession of severe shocks, and ever since then the prices have been uncertain, and have depended entirely on momentary circumstances. In consequence all the large consumers refrained from entering into contracts, and confined themselves to hand-to-mouth transactions. Now, however, these feverish symptoms are passing away, and the prices may be fixed with some feeling of security for a considerable period ahead, and long contracts are again being entered into. Coke is steady at 35fr., and coking coal at 20fr. to 21fr. In *fines demi-grasses* 16fr. and 19fr. are maintained as the extreme prices. Close burning coal is very firm at 15fr., and screened and nuts are at 20fr. to 21fr. Briquettes are sold at 23fr., 24fr., and 25fr. Contrary to the hopes of most of the coal producers the special tariffs of 1886 for the carriage of coal by the State railways were abolished on the first of the month, and since then the Grand Central Railway has followed the example. The carriage of goods by the State railways has increased very much during the week ending the 2nd inst., as compared with the similar week in 1889. Most of the increase is due to the greater business in coal and coke.

THE IRON MARKET.—The most important event of the past week in the iron market has been the decision of the ironmasters' syndicate to maintain the present prices of bars and sheets. For some considerable time the demand for finished iron has been flagging, and it was thought by some that the prices should be reduced in consequence. On the other hand, it would be suicidal to lower the prices on account of the cost of labour and raw material. The difficulty of the position is all the worse on account of the fact that the foreign producers are ready to step in at any moment. Owners of rolling mills are considering the advisability of limiting their output. All the machine shops have sufficient work to keep themselves going for the present, but forward orders are not so plentiful as might be desired.

THE LINEN TRADE.—The sales of Russian flax and tow have been less important than those of a few weeks back; prices are weak, though no actual lowering has taken place. The Ghent market, on the other hand, has been well supplied, and the demand was bright; prices were raised all round, and the current sales in threads were satisfactory. The demand for cloths is good, but most of the houses have no stock.

DÜSSELDORF, 11TH MARCH, 1890.

COAL.—The demand for coal continues unabated, and production is being pushed to the utmost. The merchants are profiting largely by the recent rise in prices, which are fully 35 per cent. above those at which the contracts were made under which the colliery owners are now working. The situation is for the latter much less favourable than the general public are taught by the agents of the working men to believe. The trade with Hamburg and its neighbourhood continues to increase, the consignments to that district in the month of February being 55,780 tons against 52,680 tons in the same month of last year. Fresh orders are coming in freely.

IRON.—That the iron market has lost much of its life and vigour is a fact now reluctantly admitted. The action of the coal miners in disturbing the basis of trade has weakened the confidence, and interrupted the development of the business in the home markets. This slackening of the home demand has made the loss in the export trade more keenly felt, and, together, these influences have operated to change the aspect of the markets. Pig iron is now but little inquired after, and prices, in so far as they are made by the middlemen, are giving way. Manufacturers still maintain their rates. The Rhenish-Westphalian pig iron makers' syndicate has announced a production of 111,656 tons in February, against 117,778 tons in January of the current year, and 110,666 tons in February of 1889. The syndicate of rolled iron manufacturers has been prolonged till December 31st of the year 1893. Business in the market for finished iron is less active, and no transactions are now recorded above the syndicate minimum. Merchants have in some instances undersold this minimum. The tone of affairs generally is somewhat weak.

THE LABOUR QUESTION.—The agitation among the working men for an increase of wages and shorter hours of labour is extending to all classes, and is everywhere increasing in intensity. The movement has acquired such force that a general rise of wages may be regarded as inevitable. There is hardly a trade in which the operatives have not already agreed to demand better terms of their employers, and to enforce their claims by strikes as soon as the winter is wholly past. Before the end of the current year the cost of production in Germany will, for all manufactures, have been materially increased. A correspondent in Halle describes a state of things which is to be met with in all the industrial towns of Germany. He says that in his district the carpenters are asking for an average rate of 4¾d. an hour; the bricklayers demand to be paid 6d. an hour, against 4¾d. last year; the paperhangers, painters, and house decorators claim a maximum of 18s. a week for a nine hours day; and the tailors are agitating for a 20 per cent. rise. In some trades, in which work is plentiful, a considerable advance in wages has been already conceded.

LILLE, 11TH MARCH, 1890.

IRON.—The situation is not materially changed from what it was a week ago. There is a steady flow of fresh orders to the forges; but the market has lost something in strength of late. The bulk of the business transacted takes place on the basis of 160s. for bars; but some bargains have been recorded at 156s. Work is now carried on

Digitized by Google

more regularly, the supply of fuel being more abundant. Some of our manufacturers are sending iron to Germany, where the high prices now prevailing render it possible for the products of this district to be offered at rates considerably below those current there.

TEXTILE MANUFACTURES.—Business in linen goods at Armentières is considerably more active this week. Buying orders are coming to hand plentifully, and there is a prospect of continued activity for some time to come. The statistics of trade in February show that the turnover for that month was above the average. The Roubaix woollen trade is slack, but the tone of the market is good. It appears from the statistics of the trade of the Port of Dunkirk that the quantity of raw wool imported in 1889 amounted to 1,722,672 cwt. against 1,280,750 cwt. in the previous year.

FLAX AND YARNS.—There is an active market for home-grown flax, with prices tending in favour of buyers. Russian is a little more inquired after, and prices are somewhat weak. Such have been the distinguishing features of the flax trade in the week last past. Business in tows is restricted to the needs of the moment. Prices are a little lower. Tow yarns, too, have receded a point. The market is quiet for linen yarns. For jute yarns there is still a brisk demand—at least, for the fine and medium sorts. The commoner qualities are less inquired after. Prices remain practically unchanged.

AMSTERDAM, 10TH MARCH, 1890.

ACCIDENTS IN FACTORIES.—The new Association of Employers for the prevention and minimising of accidents in Dutch factories is now duly constituted, and its rules and regulations already framed and approved by a committee consisting of seven members.

RAILWAYS IN HOLLAND.—Among the new projects there is a line from Hellevoetsluis, the port of the German Ocean where William III. took sail in 1688 to Rotterdam, and a direct railway between the latter city and Amsterdam. Hellevoetsluis is well known among sailors as a splendid harbour, accessible at all times to all ships, and it would no doubt be used much more than at present if it could be easily reached by rail. As soon as the acquisition of the Dutch-Rhenish Railway by the State is an accomplished fact, and the States-General shall have passed the proposed agreements with the Holland Railway Company and the State Railways Company, the different stations at Utrecht are to be pulled down and replaced by one large central station, which will accommodate the large exchange traffic between the north and the south, the west and the east. Utrecht, being in the middle of the kingdom, will become its most important railway centre. Recently the giving way of the foundations of the Central Railway Station at Amsterdam has been referred to. Now a similar phenomenon is engaging the attention of the railway department at Feyenoord, on the other side of the Maas, at Rotterdam. The large railway embankment there shows signs of subsidence, and the Government, in conjunction with the town authorities of Rotterdam and the directors of the State Railways Company, has appointed a technical committee to inquire into the probable causes.

TOLLS ON CANALS AND ROADS.—The Government Bill for the abolition of the dues on the Amsterdam ship canal will shortly come on for debate in the Lower Chamber of the States-General. As soon as it is passed by both Chambers the Minister of the Means of Communication will take in hand the more comprehensive scheme of abolishing tolls on Dutch canals and highways generally. The Minister is in favour of such a measure, but the question is whether it may be feasible at the present moment. In order to ascertain this his Excellency intends to appoint a small committee of inquiry, with power of hearing evidence and preparing a scheme for acceptance. The chief difficulty to be met is, no doubt, to find the means of replacing the source of revenue to be sacrificed.

FRENCH ENGINEERS IN HOLLAND.—The Royal Institute of Civil Engineers of Holland will meet shortly to settle the programme of the next summer conferences. It is proposed to invite to these and Holland generally the leading members of the French Société des Ingénieurs Civils in Paris, particularly Messrs. Eiffel and Decauville.

CO-OPERATION AT DELFT.—The Co-operative Society of Delft, whose 309 members chiefly beiong to the artisan class, has done well in 1889, and a dividend of 5½ per cent. is available for distribution among the shareholders.

TIN IN THE DUTCH EAST INDIES.—The success of the Singkeb Tin Company has stirred the ambition of explorers and promoters in other directions. There is little doubt but that numerous other islands of the Archipelago, besides Banca, Blitong, and Singkeb, contain either tin ores or alluvial tin, and small syndicates are being formed to explore several of them, of course with a view of bringing out companies if the trial borings and washings should prove successful. The Dutch-Indian Government is encouraging these efforts of private enterprise as much as possible by sending out its own engineers for the purpose of assisting in the work of exploration. That such work is not always without its dangers was shown the other day on the large island of Flores, mainly a dense jungle inhabited by savages, over whom the Dutch hold a merely nominal sway. A party, formed by the Government engineer, Van Schelle, was attacked by a large number of Malays armed with klewangs, or swords. Many were shot down by musketry fire, but Mr. Van Schelle and his assistant received dangerous klewang wounds in the back. The Government is sending a small expedition to punish the islanders for this outrage upon its officials.

COPENHAGEN, 8TH MARCH, 1890.

A RAILWAY FOR RUGEN.—The island of Rügen in the Baltic is to have a railway, which will, naturally, be of modest proportions. Its length will be only a little over 8 kilometres, and the whole cost is calculated at £3,000. It will connect the two seaside places, Ahlbeck and Heringsdorf, with Swinemünde. It is expected to be a great boon to the fishing people, but it may, however, obtain its greatest importance through its possibly becoming a link in a new connection between Sweden and the Continent, which is under contemplation.

FISHING IN NORWAY AND SWEDEN.—Great efforts are being made in both Sweden and Norway to advance this important and lucrative industry. A number of fishing smacks have been purchased in England, new steamer and railway communications are being opened out, the construction of boats, carriages, and utensils is being improved, ice depôts are being erected, &c. All along the Norwegian coast the cod fishing is going on; the results are satisfactory and the prospects are hopeful. The fish are mostly large and the livers good. Last season's herring fishing in Sweden has not been quite so good as the previous one. The quality of the salted herrings is, however, generally excellent. The following figures will show the increase of the Swedish export of fish during the last few years:—

	1886.	1887.	1888.	1889.
Fresh fish ... kilogs.	22,131,000	34,098,000	38,251,000	55,783,000
Salted, dried, smoked, &c.:				
Herrings... ,,	1,192,000	2,598,000	5,526,000	20,507,000
Other fish. ,,	488,000	325,000	877,000	664,000

THE INTERNATIONAL EXHIBITION AT STOCKHOLM, 1892.—In two years' time the Swedish capital is going to hold a large Exhibition, which is sure to attract considerable attention.

NEW PETROLEUM STEAMER.—A new petroleum tank steamer was launched on the 27th ult., from the Kockum Engineering and Shipbuilding Company, Malmö, Sweden. Its capacity is 600 tons. The building of tank steamers has of late been a very important specialty in Swedish shipyards, and orders continue to be forthcoming, especially from Russia.

MADRID, 10TH MARCH, 1890.

ACCUMULATORS IN SPAIN.—Accumulator works have lately been established in this country, though on a very moderate scale. It is surprising, however, that the accumulator works at Madrid have to pay much heavier prices for lead, sulphur, &c., than in London, and as coals are also dearer, the accumulators made in this locality are as dear as those which are imported. The central telegraph station at Madrid has adopted accumulators. These accumulators have a great future before them at Madrid on the tramways.

TAR DISTILLING IN SPAIN.—The well-known house of Messrs. Burt, Boulton, & Haywood have established a branch house with riverside front at Bilbao for carrying out the business of tar distilling. They supply already by far the largest quantity of pitch used in Spain for patent fuel, and their Bilbao establishment will be a great aid to coke making.

SPANISH PIG IRON.—Some English papers have been questioning whether it can pay to ship to England pig iron instead of iron ores. If the Asturian mines could give coals in proportion to the demand, and if good coke ovens were in existence at Bilbao, hematite pigs could be made for less than 42s.

DEATH OF THE MARQUIS OF MUDELA.—The second Marquis of Mudela, Don Francisco de las Rivas, died on the 5th inst. at a comparatively early age. He inherited only eight or nine years ago one of the largest fortunes of this country. He owned the largest wine business in Spain or in any country in the world, and was also interested in four blast furnaces at Bilbao. His usual crop of vines yielded 12,000,000 bottles every year, and his make of hematite pig iron came up to 80,000 tons.

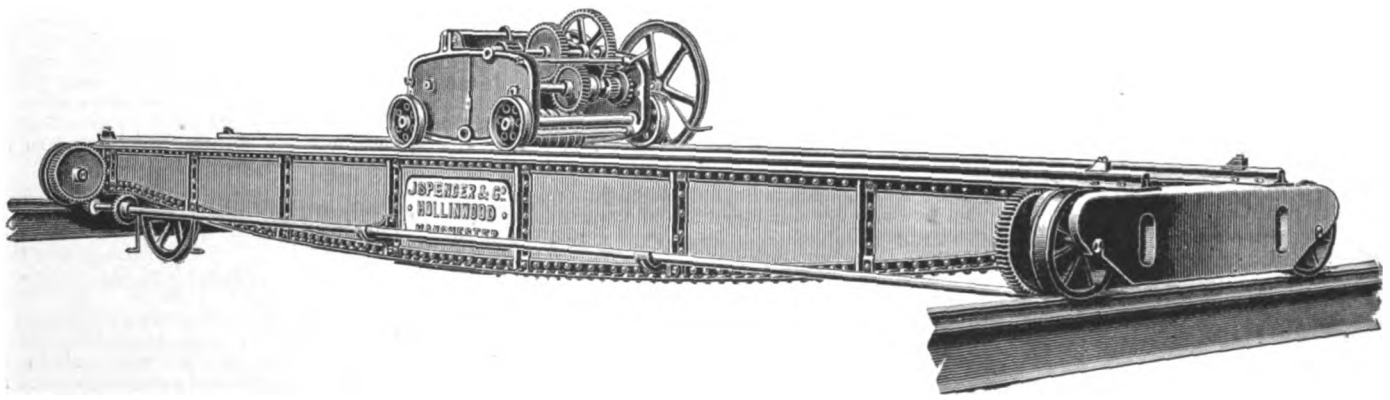
NEW YORK, 1ST MARCH, 1890.

THE COAL MARKET.—The anthracite coal trade remains dull and depressed. The production of coal even at 2,000,000 tons per month is probably greater than the consumption, and but little more than that was used in January. The demand for pea and buckwheat coal is very large, and prices are a shade higher, and are now better than for two years back. Furnace sizes are well taken, but the domestic sizes are very dull. Up to date the amount of coal sent to market is about 360,000 tons less than in 1889. The present restrictive process is costly, and a large part of the trade is still in favour of the entire closing down of the mines. The powers in the trade believe that the present and future restriction which will be ordered will, before the end of the spring months, put the trade in fair condition. The cutting of rates has caused three of the largest shippers of anthracite to cut down the nominal rates of all sizes above pea from 10 cents to 25 cents per ton. There is considerable coal to be had, however, at even lower rates.

AMERICAN TIN ORE.—The Sioux Reservation having been at last opened for settlement, the famous tin mines in the Black Hills will be worked to their fullest extent. Besides the railroad lines, which have already been surveyed and will be laid as soon as possible, to cross the reservation, there are a number of important additions to the roads in the Black Hills district which will open up the richest of the mines. The railroads and miners of the Hills have determined to turn their first attention to the tin. None of the gold mines are to be abandoned, but, with the proposed tariff to give them a start, they will, within a few months, be prepared to furnish all the tin needed in the United States.

AN INLAND SHIP CANAL.—A delegation from Delaware and Maryland have appeared before the River and Harbour Committee of the House to advocate the construction of a ship canal between Chircoteague and Delaware Bay. This is an old project, but is to be pressed with renewed vigour during the present House. The breakwater at Lewes, Delaware, is an altogether insufficient protection during severe weather, many vessels being lost there every year. The ship canal can be constructed, it is estimated, at a cost of only $300,000, and Congress is asked to appropriate one-third of it this year to begin the work. This canal, when finished, will afford shelter for vessels in the harbour of Lewes, and will also be of great commercial value as a waterway. It would also be of immense strategic value in time of war as one of the chain of inland water communications along the Atlantic Coast. Plans for the canal have been approved, and the appropriation is recommended by the Chief of Engineers.

THE SEAL FISHERIES.—The Secretary of the Treasury has opened the bids for the Alaska fisheries. There were twelve altogether, and they were all put in on the last day. Any one of these bids more than trebled the amount the Alaska Commercial Company is now paying. This company pays now $65,000 per year, and $2·61¼ per skin taken, and the same company bids $50,000 per year and $6·74 for each skin taken, besides doing the other work required by the Government. In the old contract there was a clause requiring the payment of 55c. per gallon for all the oil extracted from the seals, but on the representation that this oil was valueless the payment was, by some authority unknown, remitted. That the oil is worth a great deal the bids just opened show, as amounts varying from 25c. to 55c. per gallon are offered. The following are the principal bids:—The American Fishing and Trading Company of San Francisco, $305,000 per year rental, $4·12 for each skin, and 25c. per gallon of oil; Alaska Commercial Company, $50,000 per year, $6·75 for each skin taken, or to pay the United States any larger amount offered in good faith, besides establishing dwelling-houses, schools, hospital, regular mail service, &c. The North American Commercial Company of San Francisco offers $55,200 per annum, and $10·75 for each skin, with the express understanding that the catch shall not be limited to less than 100,000 after the first year; or they will give the Government 45 per cent. of the gross receipts for the sale of the seals; or they will pay 10 per cent. more than offered by any other company. The contract will not be made until sufficient time has been given to thoroughly study the different bids.



RAILROAD PROSPERITY.—The railroads of the country were never earning more money than at present. In January the increase in gross earnings over last year was more than $4,000,000. It is likely that the net earnings will also be very large, as, except on a few Western roads, the weather has been such as to make expenses light for the season of the year. In January, 1889, returns from 154 roads, operating 82,040 miles, showed $30,289,211 gross earnings, while from the same number of roads in 1890, operating 83,983 miles, the gross earnings were $34,292,250. The increase—over 13 per cent.—is the largest ever made in January, and is the fourth successive January increase. The business of railroads is not only heavy, but, in the opinion of railroad men, it will continue heavy during the entire year.

THE IRON AND STEEL TRADE.—There is nothing new in the iron market. Consumption is still heavy, but there are no attempts to make new contracts. Buyers are holding off until forced to come in, and sellers are equally slow in making any concessions in prices. In pig iron there is little change. The entire output is absorbed generally in small lots, but there is no disposition to buy large quantities at ruling rates. The Western markets are weaker because of the increased competition of Southern iron, which will be shortly increased by the blowing in of several of the larger furnaces. This will, probably, affect the entire market, unless consumption increases again shortly. No. 1 foundry is selling at $20 to $20·50 per ton, No. 2 at $18·50 to $19, and grey forge from $17·50 to $18 delivered. The market for manufactured iron scarcely holds its own. Prices are nominally unchanged, but the trade is dull, and the week's sales are only sufficient to cover the week's production. Mills are still busy on old orders. Steel rails are quiet. Prices are firm at $35 per ton at mill. Although there is not much demand at present, there are some fair-sized orders in prospect, and it is likely that a good deal of business will be placed during the next month. Steel in other forms is dull and unsettled.

IMPROVED TRAVELLING CRANE.

CONSTRUCTED BY MESSRS. J. SPENCER & CO., ENGINEERS, HOLLINWOOD, NEAR MANCHESTER.

IMPROVED TRAVELLING CRANE.

THE above illustration shows an improved travelling crane made by Messrs. J. Spencer & Co., engineers, Hollinwood. It is specially designed to give the quickest speed of lifting with a minimum expenditure of power. The weight of the various parts is reduced as far as possible consistent with the provision of the necessary margin of strength. The cross girders are bow-shaped riveted plate girders, sustained at the ends by cast-iron carriages. The crab is provided with single and double spur gearing, the change being made by a claw-clutch. In order to avoid overlapping of the chain the barrel is grooved, and is sufficiently large in diameter to wind on the entire length of the chain. All the motions are controlled by hand chains from below, but crank handles are also fitted to permit of control being obtained from a platform. In the smaller sizes—that is, up to 10 tons lift and 30ft. span—the main girders are made of rolled iron.

INSTITUTE OF MARINE ENGINEERS.

A MEETING of the Institute of Marine Engineers was held on the 4th inst., when Mr. W. J. Nowers Brett read a paper on the "Friction of Screw Propelling Engines." The paper dealt with the losses due to friction in various parts of the marine engine and shafting from the pistons to the propeller blades. The question of rough surfaces and lubrication was first referred to, also the small bearing surfaces sometimes found in engine shafting and the consequent trouble. The forms of steam admission valves in use and the rejection of the slide for piston valves in more recent types of engine were noted, and the advantages of the piston valve pointed out. Reference was made to the different kinds of material used for bearing bushes—*e.g.*, lignum vitæ for the propeller shaft in the stern tube; brass, white metal, or phosphor bronze for the various other bearings. It was suggested that it would be an advantage to use roller bearings for some of the shaft journals, and a model of roller bearings suitable for tunnel and other shafting, made and patented by Mr. Leslie, one of the members, was exhibited.

A passing reference was made to shafting being out of alignment, and the advantage of having flexible couplings fitted to the tunnel shafting to obviate the trouble frequently experienced, whether due to original lining off or to the alterations which take place from time to time in the hulls, due to the loading of varying cargoes or to structural weakness. The best material to use for propeller blades was considered, and reference was made to the extensive corrosion or pitting found to take place at the points of the blades in both cast iron and steel after a few months' running.

In the discussion the question of the most suitable form of packing rings for pistons was considered, and several members expressed opinions favourable to a series of narrow cast-iron rings as being economical and least liable to cause excessive friction. The once common practice of giving packing rings too much compression was commented upon strongly, as this led frequently to a system of packing being unjustly condemned on account of undue compression being placed on the rings.

The great unbalanced weight of the slide valves fitted to many engines—especially the high pressure valve of compound engines—was remarked upon as obviated to a certain extent in more recent types of engines by the piston form of valve, which cannot, however, be looked upon as perfect, as regards keeping steam tight for a long period. The arrangement of a balanced or equilibrium slide valve patented by Mr. Church was highly commended by several present who were acquainted with its merits. The introduction of phosphor or manganese bronze and Delta metal for propeller blades was considered by those who had had experience of them to be a very great improvement as compared with cast iron or steel, although expensive in first cost. The improved speed of the ship, the reduced drag on the engines, and the fact that the action of the water at the periphery of the propeller does not cause any pitting action such as is found in the cases of iron, and especially steel blades, involving frequent renewal, all tended to the view that in the end the new alloys were the more economical.

The principles of friction on moving surfaces were discussed, and an interesting series of remarks on this subject, with data gained from experiments, were given by Mr. McFarlane Gray.

The proceedings were brought to a close by votes of thanks to the author of the paper and the Chairman. It was decided to continue the discussion at a future meeting early in April.

The annual general meeting will be held on the 28th March, when the financial and other reports for the first year of the history of the Institute will be submitted and the result of the voting papers for the election of the new Council declared. We hope, now that the Institute has gained confidence and is fairly established, the time is not far distant when it will have premises of its own, and rooms for educational and other purposes worthy of the name.

LONDON ASSOCIATION OF FOREMEN ENGINEERS.

UNDER the presidency of Mr. J. E. Bartle, Professor W. C. Unwin, F.R.S., gave on Saturday, the 1st inst., at the Cannon Street Hotel, before the London Association of Foremen Engineers, a very interesting lecture on the "Objects and Methods of Steam Engine Trials." In the course of his remarks the Professor said that it was to engine tests having for their object the investigation of the thermodynamic actions which went on in the engine that they owed every real improvement in the steam engine. In such tests—tests that went beyond the simple testing of the feed water and coal—some theoretical calculations of a somewhat recondite character were necessary, and it was by that means that they were able not only to know how much coal was burned, and how much power was developed, but also to measure how much heat was developed in the furnace, how much got into the steam, and where the loss occurred, and thus to ascertain what losses were important enough to be worth trying to diminish. Beyond the immediate commercial advantage of a thorough engine test, it was an addition to the sum of knowledge available for further improvement of the steam engine. And, in connection with the question that was agitating the engineering world at the present moment, as to whether jackets were useful or useless, he ventured to say that if a few complete marine engine tests had been made there would have been no room for doubt at all, and a considerable sum annually would have been saved. The prime object of an engine test was usually to determine the cost of power, and for that purpose a combined engine and boiler trial must be made. But such a trial always left an element of uncertainty, as they might have a good engine and a bad boiler, or a good boiler and a bad engine, and they were therefore unable to tell how much credit or discredit attached to the engine maker and how much to the boiler maker. For a single boiler trial the most accurate plan was to draw the fires and weigh them at the beginning and the end of the trial. Steam was got up and the fires got into average condition, the test being taken to begin the moment the fire was put back and the steam valve opened. At the end the fire was again drawn and cooled down; it was then separated by sifting into ash, cinders, and clinkers, the cinders which did not pass through a $\frac{1}{2}$in. sieve being treated as unburned coal and the ash and clinkers as incombustible refuse. Such trials, however, were unsatisfactory if they were not continued for twelve, and, if possible, for twenty-four hours. The lecturer usually noted the water level at the beginning and brought the water to the same level at the end. The amount of air used was the next important measurement, and this he generally accomplished with the aid of anemometers at the mouth or openings in a wooden box in front of the furnaces. Perhaps a better way, however, was to analyse the furnace gases. Knowing how much carbon had gone in the furnace gases it was easy to find how much air had gone into the chimney. A very few ounces of gas, however, had to be taken as sampling a very large quantity—perhaps 50 tons of furnace gas. The measurement of the temperature of the furnace gases presented also some difficulty, and in this connection he had used Murrie's pyrometer, and had found it satisfactory so far as he had had opportunities of testing it. A calorimeter for estimating the carbon value of the fuel would be very useful if there was a reliable one, but they could to a great extent get over the difficulty of not having a quite satisfactory fuel calorimeter by using a standard coal such as Nixon's navigation in all boiler trials. An engine test, when tolerably complete, was more difficult and required more preparation than a boiler test. In the first place it was necessary to cut and blank flange as far as possible every connection through which leakage could occur. The principal measurements to be made were the measurement either of the feed or condensed steam, or both, and from this the weight of the steam used was determined. Next came the measurement of the indicated power; then the heat rejected must be determined by measuring the volume and rise of temperature of condensing water; and lastly, the amount of jacket drainage must be measured as a means of determining the heat given to the cylinder from the jackets. The lecturer concluded his address by exhaustively describing the measuring arrangements adopted at the Central Institution.

In the discussion that followed the lecturer was asked his opinion about steam jackets. Professor Unwin, in reply, said that a jacket was always, in every case, useful. He had taken the trouble to go through fifty experiments of a parallel character with and without the jackets, and in only one case did he find that there was not a very distinct economy gained by the use of the jacket, and that he attributed rather to an experimental error.

NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS.

Mr. C. Furness, Mr. Henry Withy, and Mr. R. W. Vick, the principal members of the firm of Edward Withy & Co., West Hartlepool, have recently given a sum of money to this Institution for the founding of a Gold Medal Fund, so that a valuable gold medal, with a certificate, may be given each year for the best paper on Engineering and for the best paper on Shipbuilding. It is hoped that the giving of these medals will very greatly stimulate the advancement of engineering and shipbuilding in the North-East Coast ports. We understand that all members are eligible to compete for these medals with the exception of the Executive Council, who have the awarding of the medals. The above-named Institution is in a flourishing condition, having nearly 1,000 members, who are nearly all heads of departments. The result is that the papers read are generally of great practical value to shipowners, engineers, and shipbuilders. The Institution has also the election of two members upon the Expert Committee of Lloyd's for the consideration of all plans, new designs, &c. The Institution has extensive offices in Newcastle-on-Tyne, which contain a good library, but although the offices are in Newcastle the Institution does not restrict the reading of papers to that town alone, but arranges for some to be read at Sunderland and Hartlepool.

Notices of Meetings.

THIS WEEK.

South Staffordshire Institute of Iron and Steel Works Managers.—Saturday, March 15th. Mr. Herbert Pilkington, F.C.S., M.Inst.M.E.. "On the Manufacture of Basic Pig Iron."

NEXT WEEK.

Institution of Civil Engineers.—Ordinary meeting, Tuesday, March 18th, at 8 p.m. Paper to be read: "Lough Erne Drainage," by James Price, Jun., B.E., M.Inst.C.E. Students' meeting, Friday, March 21st, at 7.30 p.m. "Economy Trials of a Compound Mill Engine and Lancashire Boilers," by L. A. Legros, Stud.Inst.C.E.

Society of Arts.—Wednesday, March 19th, at 8 p.m. Fifteenth ordinary meeting. "Commercial Geography," by J. S. Keltie. Sir Frederick Abel, C.B., F.R.S., will preside. Saturday, March 22nd, at 3 p.m. "The Atmosphere," by Professor Vivian Lewes.

Chemical Society.—Thursday, March 20th, at 8 p.m. Lecture by Professor Judd, F.R.S., on "The Evidence Afforded by Petrographical Research of the Occurrence of Chemical Change under Great Pressures."

The Institution of Electrical Engineers.—Thursday, March 20th, at 8 p.m. "Alternating *v.* Continuous Currents in Relation to the Human Body," by H. Newman Lawrence and Arthur Harries, M.D. (if discussion on previous papers allow).

Physical Society.—March 21st, 1890. Papers to be read: 1, "On the Villari Critical Point of Nickel," by Herbert Tomlinson, F.R.S.; 2, "On Bertrand's Idiocyclophanous Prism," by Professor Silvanus Thompson.

Royal Institution.—Friday, March 21st, at 9 p.m. Professor G. F. Fitzgerald, M.A., F.R.S., on "Electromagnetic Radiation." Saturday, March 22nd, at 3 p.m. Lord Rayleigh, on "Electricity and Magnetism."

PRICES CURRENT, 12th March, 1890.

Quotations at per ton, unless otherwise specified.

PIG IRON—BRAND "CARRON."

Present prices of "Carron" Pig Iron are as follow:—

	No. 1.	No. 3.
Prices, per ton ...	77/-	66/6

F.O.B. Grangemouth or F.O.R. Carron Works, Stirlingshire.
Terms: Cash on 10th of Month, following delivery.

	Per Ton Extra.
Delivery at Leith or Granton	1/9
Do. at Broomielaw, Glasgow	2/-
Do. at London (over ship's side in Thames)	6/-
Do. at Liverpool (alongside export vessel)	—
Do. at do. (traders' dock)	—
Do. at Hull (on quay)	5/-

„ Ship and Girder			8 15 0	„

Market quiet.

Messrs. Carrick & Brocklank, Manchester, report as follows:—

Copper: The fluctuations in Chili bars during the past week have been but small, quotations to-day being slightly lower. The market is still inactive, consequent on the continued depression in pig iron, and but a very limited business is being done. The demand for manufactured continues slack, and prices to-day are £62 sheets, £65 bottoms.

Tin: A steadier feeling has been noticeable during the week, and prices of foreign have advanced about £1 per ton. To-day's quotations are £90 17s. 6d. to £91 5s., with moderate business doing.

Lead continues very quiet, although values are a shade higher.

Spelter is lower, the demand being very slack. At the same time there is no pressure to sell, the stocks everywhere being small.

Messrs. S. W. Royse & Co., Manchester, report as follows:—

Chemicals.—The course of business in chemicals continues quiet. In alkalies especially there is little being done, and only for spot delivery, the labour troubles making the position forward very uncertain. Crystals and crude carbolic are very dull, but liquid carbolic is in rather better demand. Sulphate of copper is somewhat firmer for both present and forward delivery. Foreign white sugar of lead has been advanced, though it is difficult to see any reason for this.

FOREIGN TELEGRAPHIC ADVICES

(From our own Correspondents.)

Paris, March 13.—*Iron.*—Market hesitating. Buyers hold aloof in expectation of lower prices. Merchants quote bars at 160s. and joists at 164s., but concessions are easily obtained on orders of some importance. Prices are maintained in the markets of the provinces, but the current of business is slackening. In the Nord especially the market is quieter.

Metals.—The metal markets are dull and depressed. Copper is still quoted at the prices current a week ago; but the amount of business done is very small, so that prices are little more than nominal. These remarks apply also to tin. The supply of lead exceeds the demand, but the rates are too low to allow of any further decline. Spelter has lost the advance reported last week.

Berlin, March 13.—*Bourse.*—The market for industrial securities has recovered briskly from the extreme depression which characterised it a week ago. The recovery is in part due to the closing of "bear" accounts; but in part also it is real. Confidence has in some measure been restored, and as weak holders have been shaken out, the market is steadily regaining strength. The rise in colliery shares is from 6 to 7 per cent. There were some fluctuations yesterday; but to-day the market opened with an advance.

Iron.—The market is quiet, but there is a better tone due to greater confidence. More favourable accounts from the Westphalian coal-mining districts have raised hopes of a peaceful settlement of the wages dispute. Prices are moderately firm at 205s. a ton for Silesian bars. Founders report business brisk. Foundry coke in strong demand at 41s. 6d. to 42s. 6d. a ton delivered in Berlin.

Metals.—Business in metals is very slack. There is not much doing in copper, but Mansfeld refined maintains its position firmly at from £59 to £60. English brands a little weaker at £56 to £57. Tin dull at last week's prices: Banca, £100 to £101. Lead is less inquired after, but prices are firm: Clausthol refined, £15 10s. to £16. The market is stronger for spelter: Silesian, W.H. brand, £25 15s. to £26 10s.; ordinary, £25 to £25 10s. Antimony regulus unaltered.

Breslau, March 13.—*Coal.*—The merchants have again advanced the prices of coal 4d. to 5d. a ton, and 6d. to 8d. has been added by the retail dealers. The demand continues very brisk. The requirements of the iron manufacturers are not yet fully satisfied.

Iron.—The market is active both for crude and for finished iron. Grey pig, 85s. to 90s.; English foundry pig offered at 83s. to 84s. Demand brisk for joists, both for home consumption and for export. Hoops are much inquired after. Good business in plates, wire, and wire-nails. Prices are firm at 210s. for bars, 230s. for common plates, 250s. to 260s. for boiler plates, and 265s. for thin sheets, manufacturers' base prices; merchants' rates from 15s. to 20s. more.

Metals.—The market for zinc is still flat. Good ordinary Silesian brands are offered at £22 7s 6d. to £22 10s. There is but little stock in second hands, so that a further relapse is not to be apprehended. The tone of the market has somewhat improved. Lead is in fairly brisk demand.

Düsseldorf, March 13.—*Coal.*—The coal market is extremely animated, the demand continuing unabated, but prices remain steady. There is disunion among the colliers relative to the threatened strike; hence hopes are entertained that the conflict may be averted.

Iron.—The market for pig iron is very quiet. Both buyers and sellers are waiting for clearer indications of the course of events. Prices, which have receded a little from their highest point, are firm at the present rates. The demand for finished iron and steel has fallen off a little, wire having suffered most. The foreign demand for wire is very slack. Joists are more inquired after. Prices unaltered.

Ghent, March 13.—*Flax and Yarns.*—The market has further improved for home-grown flax; the demand being very brisk and the quantity on offer not large, prices are very firm. In Russian flax there is but little doing. There is a fairly strong current of business in yarns, the demand being chiefly for the finer numbers. Prices remain unchanged. Coarse tow yarns are utterly neglected.

HOME INDUSTRIES.

LONDON 13TH MARCH, 1890.

THE MONEY MARKET.—The money market has now assumed an aspect of ease, with money in plentiful supply and lendable at about 3 per cent. The fear of gold withdrawals to New York is not altogether over, seeing that the bullion stock of the Associated Banks in New York has been steadily increasing; but the rate of exchange between the two countries renders the export of gold from London to the States improbable for the present. The stock markets, after a fit of depression, have improved greatly in tone this week. The Stock Exchange is disposed to take a hopeful view of the outcome of the wages dispute in the coal districts, and consequently home railway stocks fairly maintain their prices. North-Easterns, which are always most sensitive to influences of the kind, are as strong as any railway security in the list. Among American railways there is no striking feature, but London is inclined to be steadier and more "bullish" in tendency than New York. Foreign stocks are firm on the whole. Argentine securities fluctuate considerably in sympathy with the rise and fall of the premium on gold at Buenos Ayres, and confidence in them has been greatly shaken. Gold mining shares have been in greater favour than for some time past. The more substantial of the Transvaal mines are showing improved prices, and the shares of the Indian mines have also been freely bought. There has been no movement of significance in industrial shares, save a drooping inclination among the securities of the electrical companies. The nitrate group has not yet returned to favour in the market.

COMPANIES.—The following companies have been registered since our last report:—Thomas & J. S. Turner, Ld., with a capital of £20,000, to carry on the business of gunmakers, &c.; The Newcastle Breweries, Ld., with a capital of £400,000; The Jersey Mill Co., Ld., with a capital of £2,000, to carry on the business of spinners, bleachers, &c.; R. & W. Wilson & Sons, Ld, with a capital of £25,000, to carry on the business of iron and tinplate workers, japanners, &c.; The Jersey Tinplate Co., Ld., with a capital of £20,000; The British Standard Manufacturing Co., Ld., with a capital of £5,000, to carry on the business of rubber stamp pad manufacturers; The Liverpool and Galway Steamship Co., Ld., with a capital of £10,000; Smith Patent Engineering Co., Ld., with a capital of £7,000, to carry on the business of engineers; The Morgan Crucible Co., Ld., with a capital of £300,000, to carry on business as crucible manufacturers, &c.; The Saline Syndicate, Ld, with a capital of £10,000, to carry on business as brine owners, salt manufacturers, &c.; The Trevennick Mining Syndicate, Ld., with a capital of £3,525; The British Mexican Exploration Syndicate, Ld., with a capital of £25,000, to carry on mining operations in Mexico; The Chorley Colliery Co., Ld., with a capital of £15,000; The Tewkesbury Brewery Co., Ld., with a capital of £100,000; The London Graving Dock Co., Ld., with a capital of £40,000; The Watts Steel and Iron Co., Ld., with a capital of £250,000; The Oxford Mill Co. (Rochdale), Ld., with a capital of £60,000, to carry on the business of cotton manufacturers; Varley, Bros Ld., with a capital of £8,400, to carry on the business of dyers and finishers.

BOARD OF TRADE RETURNS.—The prominent feature of the Board of Trade returns for February is the general decrease in the imports, which amounted in value to £31,018,842 for the month as compared with £32,340,096 in February, 1889, being a falling off of £1,321,254. The decrease is largely due to smaller importations of cotton from Egypt and of wool from Australia. The exports are again very satisfactory, amounting to £21,084,228 as compared with £18,670,352 in February, 1889, an increase of £2,413,876. Machinery and millwork were exported to the value of £1,179,616 as against £981,378 in the same month last year; hardware and cutlery to the value of £212,430 against £237,328; implements and tools, to the value of £106,737 against £74,946; and telegraph wires and apparatus connected therewith, to the value of £201,594 against £32,086. The exports of yarns and textile fabrics amounted to £9,553,871 against £9,063,994 last year, and chemicals to £725,887 against £603,427.

LONDON CONCILIATION BOARD.—We have already dealt very fully with the scheme which has been proposed by the London Chamber of Commerce for arbitrating upon labour disputes. They are now issuing circulars to all the labour organisations in London with a view to these associations sending delegates to represent them at a meeting to be held on the 16th proximo. Twelve representatives of labour will then be elected to sit on the London Conciliation Board. It is also proposed to form separate committees for the various trades.

THE GRINNELL SPRINKLER.—Messrs. Dowson, Taylor, & Co. have just published two circulars relative to the performances of the Grinnell Sprinkler. It appears from them that up to the end of last year 593 fires were extinguished by the sprinklers, and that the average loss as stated by insurance companies has been £49. These facts show the great utility of these extinguishers.

FIRE ENGINES ON THE THAMES.—The London County Council, having dealt with Captain Shaw's request for more escapes and more men, is now giving its attention to the fire engines, and it has been decided to accept Messrs. Shand, Mason, & Co.'s tender to supply two powerful steam fire engines for use on steel rafts on the river. The joint capacity of the new engines will be 2,700 gallons per minute.

THE ROYAL METEOROLOGICAL SOCIETY.—At the ordinary meeting of the Society, to be held at the Institution of Civil Engineers, 25, Great George Street, Westminster, on Wednesday, the 19th inst., at 7 p.m., the following papers will be read:—"A Brief Notice respecting Photography, in relation to Meteorological Work," by G. M. Whipple, B.Sc., F.R.Met.Soc.; "Application of Photography to Meteorological Phenomena," by William Marriott, F.R.Met.Soc. After the reading of these papers the meeting will be adjourned, in order to afford the fellows and their friends an opportunity of inspecting the Exhibition of Instruments illustrating the application of Photography to Meteorology, and of such new instruments as have been invented and first constructed since the last Exhibition. The Exhibition will, at the request of the Secretary of the Institution of Civil Engineers, be open in readiness for the meeting of that Institution on Tuesday evening, the 18th inst., and will remain open till Friday, the 21st inst.

THE ROYAL INSTITUTION.—The following are the lecture arrangements after Easter:—The Hon. George C. Brodrick, three lectures on The Place of Oxford University in English History; Mr. Louis Fagan, three lectures on the Art of Engraving; Mr. Andrew Lang, three lectures on the Natural History of Society; Professor C. V. Boys, three lectures on the Heat of the Moon and Stars; Professor Dewar, six lectures on Flame and Explosives; Captain Abney, three lectures on Colour and its Chemical Action; Dr. Charles Waldstein, three lectures on Excavating in Greece; the Rev. S. Baring-Gould, three lectures on the Ballad Music of the West of England (with musical illustrations). The Friday evening meetings will be resumed on April 19th, when a discourse will be given by Sir Frederick Bramwell, Bart., on Electric Welding; succeeding discourses will probably be given by Sir John Lubbock, Bart., M.P., Mr. R. Brudenell Carter, Professor Raphael Meldola, Professor A. C. Haddon, Professor Boyd Dawkins, and other gentlemen.

MANCHESTER, 13TH MARCH, 1890.

THE ENGINEERING TRADES.—There is hardly so much new work coming forward as was the case a few weeks ago. The drooping condition of the iron market is probably keeping back a large number of orders. Generally there is a feeling that lower rates are likely to be obtained shortly. At the same time, engineers are generally so occupied with work on old contracts that they are rather indifferent about accepting new business except at full rates. There is also a probability of a movement for an advance of wages throughout the trade—in fact, the moulders have already struck work in Bolton for an advance. Thus, unless there is a considerable falling off in demand, the position of engineers will be such as to compel them to resist any reductions of price. Millwright work is generally good, and boiler makers are as full of orders as they can be. Locomotive engineers are also busy, and in this department there is plenty of work in hand. Machine tool makers have not as yet found any diminution in the demand, and are still working at the highest pressure. Some heavy tools are being made for marine work, and a number of special tools for railway purposes. Among the latter may be mentioned a lathe for a railway repairing shop, just constructed by Messrs. Hetherington & Co. It can be used as an ordinary sliding and screw-cutting lathe, and may, by the removal of the rests and the substitution of a special chuck fitted to the saddle, be also employed for boring out axle boxes. In textile machinery there is a full tide of prosperity, and everyone is employed to his greatest capacity. Ring spinning and mule spinning machinery appear to be in about equal demand, and preparation machinery of all classes is also sold in large quantities. No sign of any falling-off is to be seen in the call for spinning machinery, and makers are disposed rather to discourage than to encourage new business, except where a long term is given for delivery. Loom makers are generally well employed. Coppersmiths and brassfounders are a little quieter generally, and there is scarcely so brisk a demand existing.

THE COAL TRADE. There is some excitement in the market in consequence of the threatened general strike of miners, but it is by no means certain that this will actually take place. For all classes of manufacturing coals there is a strong demand, and the output is not more than sufficient to meet it. Indeed, in some cases manufacturers are finding it difficult to obtain supplies, while others are making strenuous efforts to lay up stocks, so as to tide them over the period during which the strike may last.

THE MANCHESTER LINEN AND JUTE TRADES.—Considerable inconvenience has been caused of late in dry goods circles here, owing to the prevalence of the malady which it has become customary to misname "influenza." Many large houses, such as that of Messrs. S. & J. Watts & Co., have had a section of their employés laid up owing to the ailment. Shipments of textiles from Lancashire centres to foreign ports have been delayed in consequence of the Liverpool dock strike, which affects a much wealthier and more important district than that which suffered when the dockers of the metropolis were struggling for their "tanner." The linen trade, notwithstanding these drawbacks, however, has been fairly brisk in the home trade sections, although, as far as export business is concerned, little of interest can be recorded. Fine linens, such as fronting varieties, are slightly dearer in certain quarters, but the tendency for general descriptions of such goods is steady. Lower qualities are unchanged. In jute goods there is a steady trade.

NEW SALT DEPOSIT.—A large deposit of salt and brine has been found at Middlewich, a small town on the borders of the Cheshire salt field. It is of good quality, and the depth of the shaft is about 100 yards.

GLASGOW, 13TH MARCH, 1890.

PIG IRON.—The pig iron market was further depressed last week by realising sales on a large scale, and as low as 50s. cash was accepted on the 6th inst. The downward course, however, seems to have been arrested for the time being, all the business done since then having been in the neighbourhood of 50s. 6d. cash. Although the cry still is that there is no business doing, the deliveries from store are going on at a great rate, with no corresponding increase of stock, as far as can be ascertained, in makers' hands. Cumberland seems to be the district most immediately affected by the very great cost of coke and raw material and wages; and at a conference of makers there a few days ago arrangements were entered into for blowing out or damping a number of furnaces.

MANUFACTURED IRON AND STEEL.—The lower prices have been attracting orders from abroad, and it is understood that during the past few days considerable contracts have been made for malleable iron for the Colonies.

THE COAL TRADE.—The uncertainty as to the action of the miners is unsettling the market to a certain extent, but there is rather more business doing, prices being firm. Export trade has been good, and the home demand for domestic and also for steam purposes has been very steady.

STRIKES. The surfacemen on the North British Railway are out on strike. They demand 2s. per week of an increase in their wages.—A strike has taken place in the shipbuilding yard of Messrs. Scott & Co., Greenock. The fitters' helpers have left work owing to a demand for an advance of wages not having been complied with.

THE FORTH BRIDGE. The inhabitants of North Queensferry are very indignant that, by the erection of the bridge, with its approach line high above the level of the town, they have been deprived of their railway accommodation. There is no station on the new line, and the old station is to be shut up. The townspeople base their claim for a station upon the terms of transfer of the old Queensferry and Dunfermline line to the North British Railway Company. At an indignation meeting held there to protest against being deprived of railway accommodation while the crowning triumph of railway engineering was at their very doors, though high above them, one speaker said that he had travelled from North Queensferry to Edinburgh in the old coaching days in a coach-and-four in an hour and twenty minutes, at a cost of 2s. 6d. He had travelled third-class, by the new route by the Forth Bridge over the same journey in an hour and three-quarters, and at a cost of 2s. 6d. This is an amusing comment upon the march of science.

EDINBURGH ELECTRICAL EXHIBITION.—The tender of Messrs. A. Macleod & Co., 98, Mitchell Street, Glasgow, for supplying the main driving and other pulleys required in the Exhibition has been accepted by the Executive Committee.

(From our own Correspondents.)

LIVERPOOL, 12TH MARCH, 1890.

THE DOCK LABOURERS' STRIKE.—This strike has unfortunately assumed large proportions, and over 20,000 men are now affected. The dispute now is not so much the amount of wages as the terms dictated by the Union men, which the steamship owners stoutly resist. Large numbers of men have been drafted from other towns, and the ships are being discharged, but there is now undoubtedly a delay, and serious inconvenience is being felt by the shippers. They are now advising their customers abroad not to ship their goods to Liverpool, but to London, Cardiff, and other ports. The men are thus practically driving the trade from the port.

THE MERSEY BAR.—The Mersey Docks and Harbour Board have instructed the well-known manufacturers of dredging plant, Messrs. Simons & Co., of Renfrew, on the Clyde, to design and construct powerful sand pumping appliances to be fitted to one of the steam hopper barges constructed by them some time ago for the Board. When completed the apparatus will be employed to cut a deep channel through the outer bar of the Mersey.

LEEDS, 12TH MARCH, 1890.

THE IRON AND STEEL TRADES.—There is hardly so much firmness in the finished iron and steel trades as was the case a few weeks ago, and the reason of this change may be found in the declining state of the warrant market, and in the agitation on the part of the miners for a 10 per cent. advance of wages. Inquiries from consumers of iron are fewer, and though, with regard to the steel trade, much business is being done in plates, there is a falling off in the demand for ingots and forgings. The demand for marine work has also fallen off somewhat lately, but it is antici-

Digitized by Google

pated that the decision of the Government to add to the fleet will give a large amount of employment in Leeds during the year. Railway material of all descriptions is wanted on a large scale for home and foreign customers, and patent steel frames for rolling stock have been ordered by several important railway companies. Although inquiries are not so numerous as at the beginning of the year, the branches of the engineering trade interested in the production of locomotives and materials used in the construction of engines and electric lighting plant, are very busy. General engineering tool makers are actively engaged, but agricultural implement makers are quieter just now. A good deal of hydraulic machinery is being got out of the shops, both for home and abroad. Leading firms have conceded an advance to moulders and boiler makers.

THE COAL TRADE.—The threatened crisis in the coal trade monopolises a vast amount of attention in commercial circles and among the public. All along the masters have contended that the prices realised for coal do not justify the granting of the 10 per cent. demanded, and last Friday they expressed a readiness to have the dispute settled by arbitration. The suggestion, however, has not met with support from the miners' leaders, and a strike on an extensive scale is imminent. The West Yorkshire coalowners, like those in the southern part of the county, are firm in the attitude which they have taken up since arbitration was suggested at the Coalowners' Federation. The bulk of the men's notices terminate this week. Meanwhile, coal is advancing in price, and manufacturers are trying to add to their stock of fuel. The Yorkshire Miners' Union, at the end of September last, had a banking account to the amount of £11,082 12s. 6d.

SHEFFIELD, 12TH MARCH, 1890.

CRISIS IN THE COAL TRADE. A meeting of the coalowners of Yorkshire was held on Monday afternoon at Sheffield, and after a long discussion on the wages question no decision was arrived at. On the whole colliery owners are decidedly against giving an advance of wages, and unless some compromise is made between owners and miners there is every likelihood of a lock-out. House coal was advanced on Monday by 1s. 6d. per ton. In the export trade, viâ Hull, the well-known Denaby Main Colliery heads the list with 12,064 tons. All local manufacturers are stocking coal to the fullest possible extent with a view to contingencies.

IRON AND STEEL TRADES. A much quieter tone has prevailed here during the past week. Few new orders have been placed on the books, and unless orders come in soon quotations must be lowered. At present there is plenty of work for all, and never at any time have Sheffield manufacturers done better work.

THE SHEFFIELD TECHNICAL SCHOOL.—The Sheffield Corporation have granted £3,800 in aid of the Technical School, where it is proposed to erect a small Siemens furnace in addition to the crucible furnace, which is almost ready. A new 50-ton Buckton testing machine of latest pattern is almost ready for erection at the school.

NORTH STAFFORDSHIRE, 12TH MARCH, 1890.

THE IRON TRADE.—There is great diversity of opinion amongst business men as to the immediate prospects of trade. Some think that the lull is but a temporary one and that prices will become firm again, and others have theories of a pessimist character. Certain it is that the demand for local brands of iron is quiet, and that as a result some concessions are being made to consumers in the matter of price. This applies to both the crude metal and the finished material.

THE COAL TRADE.—Notices have been handed in at all the collieries of the district, which terminate on Saturday next. The final result of the negotiations between the Coalowners' and the Miners' Federations is being awaited before any definite local decision is arrived at. It is hoped and believed that a strike will be avoided.

CARDIFF, 12TH MARCH, 1890.

COAL AND COKE.—The colliers' usual monthly holiday last week had the effect of reducing the total shipments, but there seems no abatement in the demand, which, in view of possible labour difficulties in the Northern districts, is exceedingly strong. Prices are firm, with, if anything, a slight advance on last week's figures. First quality is quoted at 15s. 9d. to 16s. 6d.; second, 15s. 3d. to 15s. 6d.; inferior, from 14s. 6d. No. 3 small for smiths and coking is very scarce, and for house coal the demand is still large, so much of this quality being used for bunkers.

IRON AND STEEL.—The pig iron trade continues flat, with no prospect of an improvement until the warrant market recovers itself. Steel bars show a sign of weakness, and although nominal quotations are about £7 10s., it is said that £7 has been accepted. The inquiry for rails is moderately brisk, but quotations are lower.

TINPLATES.—The tinplate trade is in a very unsatisfactory condition, and arrangements are almost complete for a week's general stoppage. The production seems to be excessive, and makers are unable to produce without loss. Iron ore continues in poor demand, but as sellers in Spain are well sold no lower prices have been accepted.

BATH AND WEST AND SOUTHERN COUNTIES SOCIETY.—This old-established Society will this year hold its annual exhibition at Rochester on June 5, 6, 7, 9, and 10, and money prizes amounting to nearly £3,000 are offered for horses, cattle, sheep, pigs, poultry, cheese, butter, cream, hops, wool, preserved fruits, &c., in addition to several gold and silver medals and plate. The display of implements, machinery, and articles of general utility is always a very large one, and among other attractive features will be exhibitions of manufactures, paintings, fruit-packing appliances, &c. The butter-making contests, which have been such interesting features of the Society's recent shows, will be again carried out, together with other interesting demonstrations of dairy practice. The regulations, &c., can be obtained of the secretary (Mr. Thos. F. Plowman, Bath), and further particulars will be found in the Society's advertisement. The Society's gold medal is offered for the best appliance for determining the amount of butter fat in milk, and also for the best method for testing the acidity in milk.

BARROW-IN-FURNESS, 12TH MARCH, 1890.

RESTRICTION OF HEMATITE OUTPUT.—The decision of the makers of hematite pig iron to blow out five or six furnaces with a view to checking speculative influences has been carried out, but there has not yet been any marked improvement in prices. Warrants are only 1s. per ton above last week's prices, but the stocks have been sensibly reduced, not only in makers' yards but in the warrant stores. The latter have been reduced to the extent of 5,302 tons during the past week, and they are now 6,512 tons less than they were in the beginning of the year. One furnace at Carnforth, one at Millom, one at Lowther, one at Harrington, and one at Maryport will be blown out before the end of the month, and it is quite possible that a sixth furnace will be put out of blast. The output will thus be reduced by 4,000 tons, and only 50 of the 79 furnaces in the district will be left in blast. Prices are difficult to quote, as makers cannot do business with the price of warrants so much below the actual cost of production.

STEEL.—The steel trade is busy industrially both in the Bessemer and the Siemens-Martin departments, but the orders coming to hand are comparatively small, and buyers of rails, ship qualities of steel, tinplate bars, and other products are evidently holding back for cheaper prices. Rails have gone down to £6 per ton, ship-plates to £8 5s., angles to £7 15s., and tinplate bars to £6 10s., but local makers are not doing business at these prices, as they have several months' work in hand.

CHEMICAL WOOD PULP. Although the new Kellner-Partington Pulp Company have not yet got their works at Barrow into full operation, they are beginning to make large deliveries of the manufactured pulp, which is in brisk demand at good prices. The sample manufactured is highly spoken of, and as a material for papermaking purposes it is in growing demand. There are indications of a very large trade in this class of material, and the success of the new works at Barrow is an already assured fact.

MIDDLESBROUGH, 12TH MARCH, 1890.

PIG IRON.—After considerable fluctuation the market has settled down at lower prices than last week. Yesterday No. 3 G.M.B. was offered by merchants at 50s. 6d. per ton, but more than 50s. 3s. could not be obtained for delivery this month. At present there is no business done for future delivery. Makers will not break their price, and are content to hold on for a better price, which they anticipate will come with the opening of the shipping season. Buyers prefer warrants, and thus it happens that, whilst makers' stocks are accumulating, the warrant stocks are decreasing. The stocks in Connal's stores on Monday, the 10th, amounted to 171,914 tons, against 176,866 tons a week ago.

SHIPMENTS OF PIG IRON.—The shipments are very poor indeed, being only about half of what they were at the same time last year. For the current month up to Monday, the 10th instant, they amounted to 12,943 tons, as against 23,824 tons for the first ten days of March last year. The shipments have fallen off all round.

MANUFACTURED IRON AND STEEL.—Finished products are flatter than last week, and the prices have fallen. There are few inquiries and no new orders. Iron ship plates are at £7; angles, £6 15s.; common bars, £7 per ton, less 2½ per cent. on trucks at works. Steel ship plates, £8 5s.; angles, £8 2s. 6d.; rails, £6 12s. 6d. per ton f.o.t. at works.

SUNDERLAND, 12TH MARCH, 1890.

SHIPBUILDING AND ENGINEERING.—The dispute between the employers and workmen in the engineering establishments has come to a crisis. The original demand of the employés was for a second shilling advance and one hour less work on Saturdays. Notices to cease work, unless the latter point was conceded, expired on the 8th inst. Fortunately, at a conference between the representatives of the two parties, on the 7th inst., it was decided that the notices should be extended to the 15th inst. A ballot is to be taken among the workmen as to whether they would accept the shilling per week increase; as to whether in such establishments where the men desired particularly to cease work at twelve o'clock on Saturdays this arrangement be conceded provided the hour was worked up during the week; and as to whether they would forego the rise of wages, and insist merely on the fifty-three hours week, stopping work at midday on the last day of the week. The Tyne, Wear, and Tees districts are all intended to be placed on the same basis, but only the decision of the Wear workmen has as yet been arrived at; it was as follows: 1,582 voted for the twelve o'clock Saturday; 18 for the employers' modified offer; spoiled votes, 3. There can scarcely, it is anticipated, be a strike now, but, in any event, it is doubtful whether it would be general, as the lesson learnt by the engineers' employés during the last strike on the apprentice question has left permanent effects.

SHIPPING.—The freight market has been unchanged during the last week or ten days. American rates, hitherto favourable to shipowners, have eased somewhat, owing to a rise in the prices of wheat in the United States and to forward fixing. The Baltic and White Sea trades are opening on less favourable terms than last year, and the Black Sea market still keeps low. Outward coal rates to the Mediterranean have slightly improved. Local coal shipments are by no means steady: during the last week, 65,231 tons were shipped, as against 78,647 tons, 56,962 tons, 75,402 tons, and 60,961 tons in the immediately preceding weeks; 38,667 tons went coastwise, and 26,564 tons to foreign ports. Coastwise shipments included 450 tons of patent fuel, 9,000 dozen bottles, 200 loads of timber, 223 tons of iron plates, 56 tons of steel plates, and 95 tons of lime.

NEWCASTLE, 12TH MARCH, 1890.

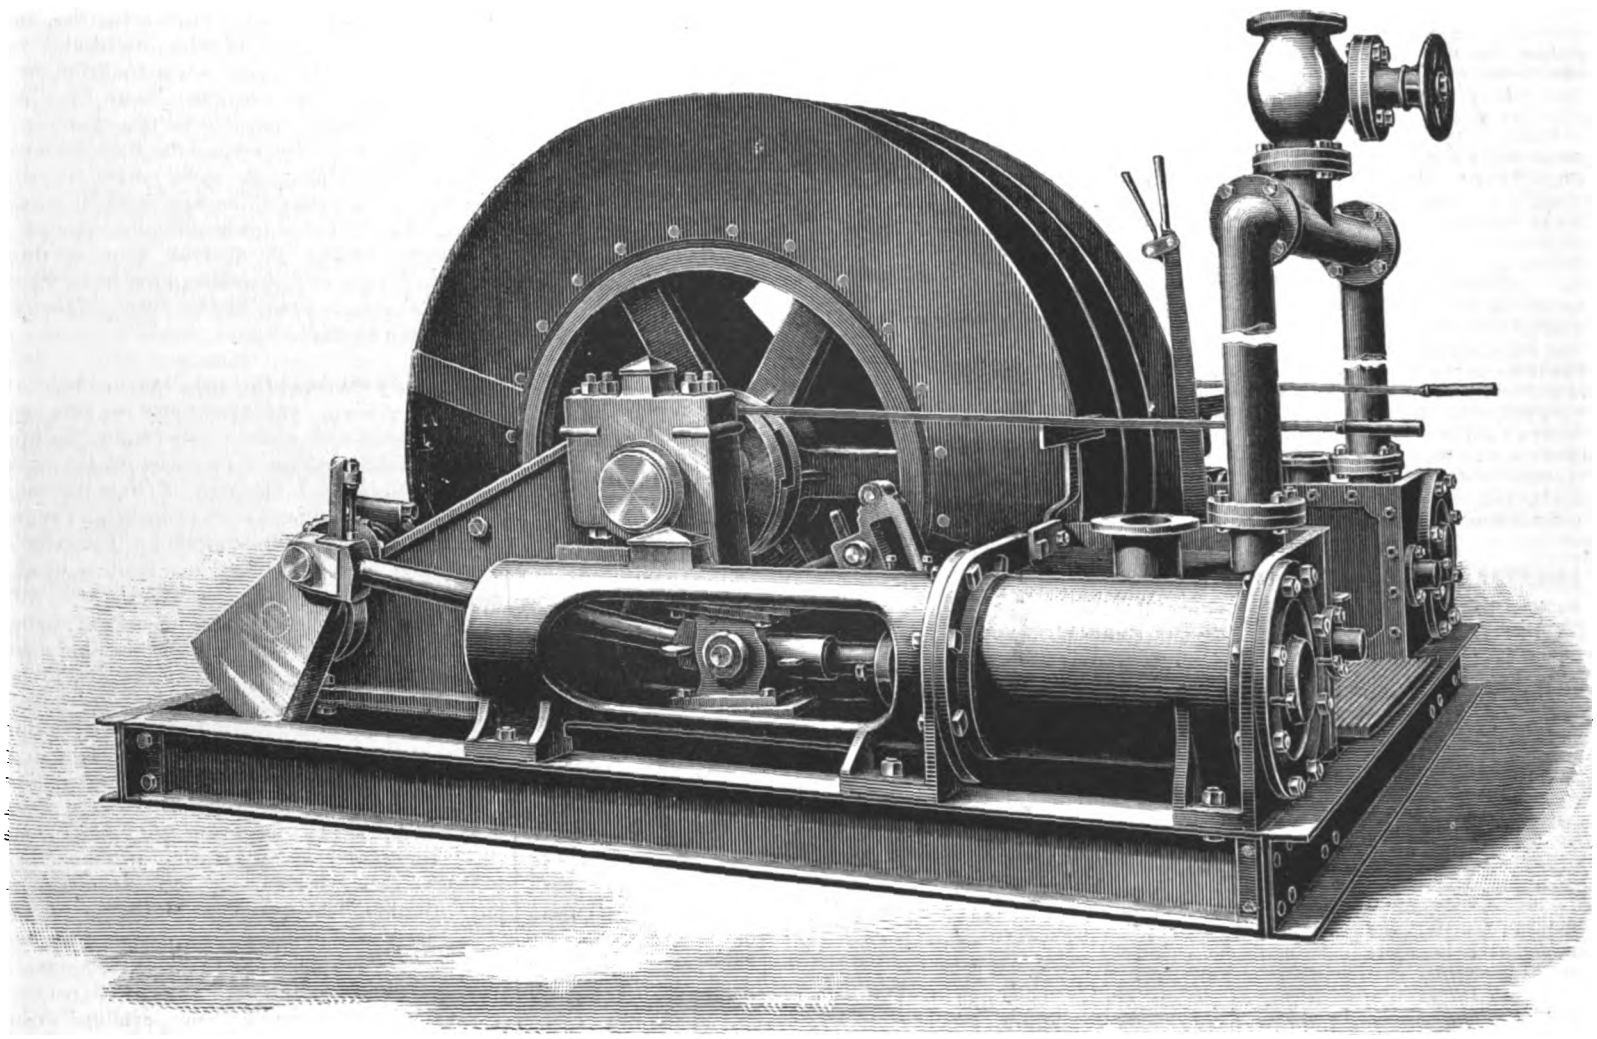
SHIPBUILDING.—The announcement has been made that a firm of shipbuilders have, through Messrs. Snowball & Co., Side, Newcastle, acquired possession of the shipbuilding yard at Scotswood, which was formerly occupied by Messrs. Campbell, McIntosh, & Bowstead, and that they intend re-starting the establishment at an early date. The yard is a very spacious one, and is fully fitted up with first-class modern machinery. We hope to be in a position to give fuller particulars respecting this very important undertaking in the course of a week or two.

DISPUTES IN OTHER TRADES. A section of the quay labourers are on strike against what they term a reduction of wages, but which is described by the employers' representatives as a rearrangement of the rates on a more liberal scale than that which existed six or seven months ago. The strike is causing some inconvenience, but this is daily being lessened by the starting of new hands. In the building trade considerable inconvenience is also felt, through a strike of the same class of workmen, for an advance of one halfpenny per hour.

THE COAL TRADE.—The shipments of coal and coke from Tyne Dock for the week ending March 8th amounted to 104,836 tons, being an increase of 9,936 tons as compared with the shipments for the corresponding week last year.

CHEMICALS.—The chemical manufacturers are actively employed in shipping goods, but stocks, with the exception of crystals of soda, are being rapidly cleared out. The lading of the steamers for Dantzig and Stettin, together with the shipment orders which have come here in consequence of the dock labourers' strike at Liverpool, are the causes of the increased activity. There is a considerable amount of inquiry going on respecting future deliveries of bleaching powder and soda ash, but manufacturers are exceedingly careful about committing themselves while so many labour difficulties appear in the way.

IRON AND STEEL.—In the pig iron trade quietude continues to prevail, holders being somewhat reluctant to sell at the rates now current. In the manufactured iron trade a fairly active business is being done, but prices have declined to the extent of nearly 20s. per ton from the highest point attained during the recent period of exceptionally brisk demand. In the steel trade values have also decreased, with the result that orders are said to be coming in more freely.



DUNDEE, 12TH MARCH, 1890.

FLAX AND JUTE TRADES.—The trade here in both branches continues quiet. Business in flax is limited both for spot goods and on contract. There is a demand of a hand-to-mouth character for flax yarns. Transactions have been carried through at low prices, but it is thought that quotations have now touched their lowest point. Manufacturers of linens are well employed, and orders are coming in with satisfactory steadiness. The finer goods are most in demand. Prices are steady. There is a steady inquiry for sailcloth at late rates. Jute of good quality is meeting with a satisfactory sale, but coarser kinds are not at present much inquired after. The demand for jute yarns has, if anything, improved during the fortnight, and prices are a shade firmer. Orders for Hessians are coming in pretty freely. The New York market is steady, and 40in. 10½oz. burlaps are quoted at 5¼c. per yard. The jute crop of 1890, it is now estimated, will exceed 2,500,000 bales. Statistics have been published giving particulars of the export of flax from St Petersburg in 1889. It appears that there was a decrease of 15,000 tons flax and 4,000 tons of codilla, compared with the exports of the previous year. The totals for the year were:—Flax, 12,723 tons, and tow and codilla, 6,829 tons. Dundee was the largest importer, taking 2,863 tons flax and 1,234 codilla. Dunkirk came next with 5,946 tons of flax and 925 tons of codilla. Montrose imported 1,458 tons flax and 738 tons codilla; Lubeck, 1,147 tons flax and 289 codilla; and Antwerp, 170 tons flax and 2,312 codilla.—It is reported that one of the largest firms in this district, that of Messrs. Cox Bros., is about to be converted into a limited liability company. The capital, it is said, will be three-quarters of a million.

SEMI-PORTABLE HAULING ENGINES.

CONSTRUCTED BY MESSRS. JOHN WILD & CO., ENGINEERS, FALCON IRONWORKS, OLDHAM.

SEMI-PORTABLE HAULING ENGINES FOR COLLIERIES.

WE illustrate above a pair of semi-portable hauling engines which have been made by Messrs. John Wild & Co., Falcon Ironworks, Oldham.

These engines have been specially designed for underground work, and are the outcome of a long practical experience with mechanical engineering work in collieries. The larger sizes of this type of engine are intended for main roads and inclines, whilst the smaller sizes are more especially intended for hauling from the workings to the main roads. The engines are mounted on a strong framework composed of wrought-iron girders and channels, whilst the drums are fitted with wrought-iron cheeks which are secured to the body of the drum by bolts. The brake consists of a cast-iron ring turned and fitted into a prepared recess in the drum. When pressure is applied to the brake lever the cast-iron ring is expanded so as to come in close contact with the drum.

In the engine illustrated above the cylinders are 12in. diameter, and have an 18in. stroke. The pistons are of the "Mather & Platt" type, 4¼in. wide. The piston rods are of the best mild steel, 2in. diameter. The stroke of the slide valve is 3¼in. The slide-valve spindles are of the best mild steel, and the outer end is carried by an adjustable slide to receive the strain due to the angularity of eccentric rod. The connecting rods are of the best hammered iron, 3ft. 9in. long, 2in. diameter at their small ends, 2⅝in. diameter at their large ends, and 2⅝in. diameter in the centre. The crank shaft is of the best mild steel, 4½in. diameter; and the cranks are of good cast iron and of the balanced type. The crank pins are of the best mild steel, 2⅝in. diameter, and 4¼in. long between collars. The drum shaft is of mild steel, 6½in. in diameter, and the bottom step of its bearings is of gun metal. The drums are 4ft. in diameter, and 12in. wide between the cheeks. The cheeks are 9in. deep, and are made of wrought-iron plates 2in. thick. The body of each drum consists of one casting. The brakes consist of cast-iron expansion rings fitting inside the drum, and they can be operated without the engineman leaving his place. All materials used are of good quality, and are adapted to their several requirements. The workmanship is of the best class throughout.

LLOYD'S COMMITTEE OF SHIP-BUILDING.

OWING, doubtless, to the continued pressure of public opinion, Lloyd's Committee have agreed to the very necessary reform of admitting representative members of the scientific societies concerned in shipbuilding and marine engineering to assist them in their deliberations. Such help will be very valuable in connection with the numerous points that arise in connection with the framing of the rules of the Society. By this recent decision the whole question of the way in which the technical department has hitherto been administered comes, therefore, prominently to the front. Up till now the Committee have necessarily been largely in the hands of their permanent employés upon professional matters. The system has worked fairly well, but not without complaints on several occasions, which the efforts of the staff have not always quite allayed. By the adoption of the change the Committee will be competent to act for themselves as regards engineering details, independently of the officials. This is a considerable gain, and one which will be much appreciated. It is a curious feature that, with the vast amount of work to be got through by the Society's surveyors, and the great interests at stake in the formation of rules to guide the building of the country's mercantile marine, the staff has been permitted to compete for essentially outside work. The primary object for which the register exists is to class ships therein so that they may pass readily from hand to hand, the class being a certificate of value. It would have been thought that the task of keeping abreast of the engineering science of the day and taking account of new developments was a sufficiently arduous one. In the course of time the original purpose for which the Society was established seems to have been somewhat overlooked. It has now come to be recognised that a person who wishes to buy a ship may call in one of the Society's surveyors to pronounce a special opinion upon her, the fees therefor going, presumably, to the Society. Surely such duties and others undertaken by the staff were never contemplated at the outset. In a competition with a public body like Lloyd's, the mass of shipbuilders and engineers must suffer. Individual experts cannot hold their own in the open market against a Society that makes the laws which govern ship construction. It has, practically, the monopoly as regards the classification of ships. The position of Lloyd's, as far as the general public is concerned, remains unique, and their certificates are invaluable. Our point just now is that the Committee ought to take a different stand and confine themselves to their proper sphere of action. We should suppose that for a powerful society to take fees, as they do, below those required by independent members of the profession, is of doubtful advantage. There has hitherto been no appeal from this state of things, the Society being a ring within itself. Now, however, that extra-professional members are to be included on the Committee, we may reasonably anticipate that they will exercise their powers to do away with any anomalies that may exist. If we take the Board of Trade, or Admiralty, which, though Government Departments, have each technical staffs, we find there is a rigid rule in each case against the employment of any of the officials on outside duties. Were it otherwise, a "leakage" of information acquired in regular hours might follow, and the Departments represented become a byeword in the country. The same objection applies to a body having functions of the nature of Lloyd's Register. To the previous want of an engineering section on Lloyd's Committee we must ascribe the state of affairs that has supervened. Now that weakness on the technical side has been admitted, any errors that have crept in will probably be soon put right and undue latitude will be partly restrained. The Society has frequently been at open war with the prominent builders of the country, the latter from their power and number never really bowing to decisions in which they had no voice. It may now be reasonably expected, with the concessions made, that the Society's action will be brought up more to the latest requirements in all the minutiæ of their very important work.

Advertisements intended for insertion in the current week's issue should reach our London Offices not later than first mail delivery on Thursday morning. Scale of charges for displayed advertisements on cover and inside pages will be forwarded on application. Orders for single advertisements must be accompanied by payment in order to insure insertion, the charge for which is 2s. 6d. for the first four lines or under, and 8d. for each additional line. Situation advertisements (Vacant or Wanted) 1s. for two lines or under, and 6d. for each additional line—which averages eight words. While all practical regularity in the insertion of serial advertisements will be observed, it can only be absolutely guaranteed in the case of those ordered to appear weekly.

As we go to press early with certain of our advertisement pages, all Alterations to Standing Advertisements should reach the Publisher not later than 2 o'clock on Wednesday afternoon in each week.

All accounts are payable to GEO. CAWLEY, 358, *Strand, London, W.C. Cheques should be crossed Manchester and Liverpool District Banking Co., Limited, 75, Cornhill, London, E.C. Post Office Orders should be made payable at the Post Office, 369, Strand, London, W.C.*

To Correspondents.

All communications intended for insertion in this Journal, or relating to Editorial matters, should be addressed to "THE EDITORIAL DEPARTMENT," at our London Offices, 358, Strand, and must, in all cases, be accompanied by the name and address of the writer. No notice will be taken of anonymous letters.

We cannot undertake to return manuscripts or drawings, and must request correspondents to keep copies.

BOUND VOLUMES OF **Industries**,

In half calf, gilt lettered, may be obtained at our London, Manchester, and Glasgow Offices, Price 20s. each.

Industries:

FRIDAY, 14TH MARCH, 1890.

THE INDUSTRIAL OUTLOOK.

THE falling off in business announced in reports from many districts in England and Scotland is not to be accounted for on any very simple grounds. The wave of good trade which arose in the late autumn of 1887, and which increased in volume all through 1888 and 1889, seems to have reached its culminating point about the close of the past year; for since 1890 began there have been in many of the leading districts distinct evidences of decline. The falling off in the placing of shipbuilding orders, though not immediately affecting the shipbuilding districts, owing to the large amount of work booked during the period of strong demand for ships, must ere long begin to tell upon shipbuilders. This diminution in shipbuilding orders is due, no doubt, to the excess of tonnage in the market seeking employment, and to the serious depression of freights in consequence. In some instances freights have fallen to about 50 per cent. of their amount a year ago. This decrease in earning power has unquestionably led to hesitancy in placing orders for new ships; but since this cause has hardly yet begun to operate upon industry directly, the causes of the depression, such as it is, must be sought elsewhere. It may be suggested that these causes may be found to exist in part in the mode in which the capital saved during the past two or three years has been invested. A very large portion of that capital has been invested in undertakings many of which are not yet, and some of which may never be, productive. A reasonable time at least must elapse before a new industry or a new company can be expected to become a good dividend-paying concern, and thus for a year or more after the foundation of a company its shareholders do not receive any income. More than this, not a few of the companies registered are conducted, within two years after promotion, with due formal solemnity through the Court of Bankruptcy, their promotion money having been in many cases squandered in a circle of unsound undertakings. Some of the companies formed within the past two years are even now exhibiting symptoms of non-productivity, to say the least. This non-fulfilment of expectations must have led to the restriction of expenditure among certain classes, and must thus have tended to depression. But perhaps a more potent influence in the alleged decrease in the volume of trade is to be found in the investment of so much of the capital in permanent and practically unrealisable forms. Should the investment result in increased production, all may come out right in the long run; but meanwhile the cost of the unrealisable investment must be met out of the produce of the year, and this may only be effected by disturbing the economic balance. Again, during the past three years there has been a steady advance in high class securities, and thus a falling off in the rate of return to capital. Some of the railway stocks have advanced from 98 and 100 to 120 and 130. Consols also are at a high price. Thus the interest payable to shareholders has been low, and their income has been to some extent reduced, while during the same period prices of many of the commodities ordinarily used in consumption have risen. The fund holder and interest receiver benefited largely by the fall in prices during the years of depression which expired in 1886, and they are now simply compelled to return the advantage they gained then. This, however, causes them to restrict their expenditure, and thus to depress demand and influence business adversely. Again, as regards the wages of labour, the rise of wages affecting the prices of certain articles, by placing a drag upon production, has been accompanied or followed by an increase in the cost of living owing to the advance in the prices of some at all events of the articles of common consumption. Thus the working class have been prevented from doing more than temporarily adding to the demand for commodities. In accounting for an apparent downward tendency in trade, there is another element in the case whose influence is so obvious that it is apt to be overestimated. This it the element of speculation. All businesses where buying forward is the rule must be more or less speculative. The temptations in a rising market, with a favourable outlook, and no apparent insurmountable labour troubles, are very strong, but a faint breath of suspicion that things are not what they seem is sufficient to kill speculation for the rise and to transform it into speculation for the fall. Although the mere gambling in foreign and home speculative stocks has comparatively little influence outside a narrow circle, saving when a new "lamb" is drawn in and fleeced, and his business, whatever it may have been, perhaps destroyed, speculation in such a commodity as pig iron, indulged in so largely at certain times by outsiders, does unquestionably affect, often seriously, the course of ordinary industry. It is clear that some portion of the downward tendency of the curve of trade is due to speculation in metals, not so much owing to the actual increase in prices brought about by speculation, as to the violent fluctuations and uncertainties of a market so influenced. It is an experience which has been met with in the recent history of the iron trade, that, contemporaneously with alterations in supply and demand for industrial purposes, which would have had the effect of raising or lowering prices as the case might be, speculative transactions entirely reversed what may be called the natural order, and caused price movements of a precisely opposite character to take place. In addition, however, to temporarily or permanently disadvantageous investments, to the element of speculation, to the checking of consumption of the bulk of the people by the rise in prices, and to the diminution in the return to capital resulting in a check to luxurious consumption, there is another element which at this time is thrusting itself very prominently forward. This element is the disturbance caused to industry and the actual loss inflicted by what are alleged to be excessive demands by labourers, and their result—strikes. That this is a real and widely influential cause of the decline in the wave may be held as proved. Waste of time, waste of resources, carried to an extent so enormous as was the case in the London dockers' strike, cannot but find economic retribution. Never before in the history of industry in this country had the labourer so much actual power as he has now, and he is roundly charged with using that power in a short-sighted and intensely selfish manner. There can be no question that there have been pretty ample grounds for such charges. The anathemas that, on the part of labour, have been hurled against the

Digitized by Google

capitalist and employing classes, even if they had been justified, might now simply be returned with interest. But of what avail would be a mere bandying of words? The main point is to arrive at a *modus vivendi*. Admitted that the practice of combination among labourers—simply a fair counterpart to combination among owners of capital—has acquired a footing so secure that any attempt on the part of Parliament to define its limits more than they are now defined by law would inevitably fail, what is to be done to prevent the occurrence of fluctuations in trade due to labour disputes and strikes is really the crying question of the moment.

If disputes between employers and employed cannot be prevented, how can they be settled so as to prevent the culmination of a strike? There can be no doubt that some of the newer trades unions, especially those which are attempting to consolidate the lower grades of labour, are managed in as selfish and short-sighted a manner as it is possible to conceive. Yet even they must be dealt with wisely, if firmly. Some patience must be exercised during their transition from wild inexperience and tutelage under professional agitators, whose influence over the men is often in inverse proportion to its wisdom. Hitherto the men have been incohesive, and frequently have suffered from being at the mercy of those who bought their labour at the lowest rate, and cared not whether they lived or died by their earnings. Thus, when one comes forward, even though he be a self-seeking charlatan, to champion them, his profession of the potency of combination and action under his guidance is easily believed, and, so long as the benefits he secures are substantial, he is caressed; when benefits cease to be secured, he is kicked. This is the history of nearly every labour combination in its early stages. Until men learn that their wages and the mode in which they spend them are integral parts in a cycle, and that alteration unwisely effected is fatal to themselves as well as to those whom they seek to strike, there can be little hope for trades unions, left to themselves, to regulate industry and commerce with advantage to society. Looking at the matter from as impartial a standpoint as one may pretend to assume, it is quite obvious that the egotism of the working class is no whit less worthy of condemnation than the egotism of the classes above it. If, as some politicians say, the industrial safety of the country cannot wisely be left to the class of landed proprietors, or, as others say, it cannot wisely be left to employers or capitalists alone, the idea which seems to be held in some quarters, that the lower ranks of labour may, by combining together and dictating terms to the rest of society, efficiently and wisely manage the terms of industrial distribution, is surely as slenderly based as any of those. As an actual practical step towards a solution of the problem of how to tide over the transition stage which must intervene before we have reason to hope that a less selfish and more reasonable spirit may pervade all classes, it is surely advisable, ere we sink into another well of depression like that from which we have so recently escaped, to try a series of experiments in arbitration. Let the dock strikers in Liverpool and the shipping companies involved submit their dispute to arbitration, rather than disorganise the trade of the port, and in effect inflict a fine upon almost everybody in the city. It is conceivable that a few days' bombardment would inflict less serious damage upon Liverpool than such a strike. With a fall in prices probably imminent, without indulging in too gloomy forebodings, there is strong reason to believe that strikes will become more and more frequent, since employés are necessarily unwilling to realise the necessity of a reduction. It is to be pointed out that strikes against a reduction of wages very rarely succeed; because a movement for reduction of wages on the part of the employers is generally dictated by the imperious necessity of a falling market. It is in the interests alike of workmen, employers, and society generally, to settle disputes which have such wide-reaching influences by reference to independent parties rather than by recourse to a war in which the onlookers are hardly the least sufferers.

AMERICAN AND ENGLISH PRACTICE IN ELECTRICAL ENGINEERING.

American practice radically differs from English in several points, and sometimes our electrical engineers are a little apt to condemn without examination anything which does not chime in with their preconceived notions. Let us, however, examine some of the more important differences, not with the view of showing that the Americans are wrong, but to see whether we are always right ourselves.

Everyone condemns the rough-and-ready way in which work is frequently put up in the United States; but it is not really a question of whether the work should be put up in a temporary way at a moderate cost or in a manner calculated to withstand the wear and tear of a century or more, but whether it is to be put up roughly or not put up at all. In our permanent work do we not spend a great deal too much in making it far more permanent than there is any need? To make anything too strong is only a less fault than making it too weak. If it is too weak it may break some day and do some damage, and money will be spent repairing it; if made too strong, capital has been foolishly sunk, and extra interest and depreciation have to be paid. If anyone proposed to lay tram lines on a macadamised road in England, and to run electric tramcars over them at twenty miles an hour, he might be laughed at; but in America they do this. There is, therefore, no room for laughing at such a plan, as it works, and what is still more important it pays, and pays well. In England, promoters would ask for capital to do the work in what would be called a permanent, solid, engineering manner, but, as we have pointed out, part of the capital may be wasted, or sunk foolishly, and it will then be more difficult to pay a good dividend. In many cases the larger capital necessary is not forthcoming at all, and so, because we cannot get the work done according to our British prejudices, it is not done at all.

The most remarkable difference is in the system of supply. In this country a maker of dynamos, for instance, does not turn out hundreds of the same size and type; he makes them of all sizes, to go at all speeds, and give all sorts of outputs. This is not because the makers like this mode of manufacture, but because the customers demand it. The maker may perhaps charge an extra price, and thus make a little more on each machine, but the price is increased, and increased price means decreased total profits to the business, though the profits per machine may be greater. Why, it may be asked, is the customer not content with the stock sizes? The customer is a small contractor, in all probability, and suffers from a weakness which seems almost universal in the electrical industry. Every electrical engineer thinks he is an inventor. Even if he does not want the plant to be made so as to work in some invention of his own, he may have a lot of little fads which have to be considered. He probably likes the dynamo to run absurdly slow or ridiculously fast, or he likes it coupled direct to some favourite engine, which, he thinks, is superior to all other engines. If the installation is large, the engineer insists on pushing in some product of his own brain, and the whole thing is called his "system." This evil becomes greater the more important the station. In the whole of the United Kingdom there are, probably, no two installations alike. In America the contractors supply the machinery of the type found by them, after considerable experience, to be good, and that machinery is put up in exactly the same way as exactly similar machinery for exactly similar purposes has been put down before, and it works without a hitch just as it worked before. The people who put it down do not settle what machinery to use, or interfere with the design in any way; they merely carry out the designs of experienced engineers, who have, under a very perfect system of division of labour, perfected every detail. Of course, the difference is that in America the plant is supplied by large contractors, and the engineers who erect it are practically the contractors themselves. The American arrangement of business tends to the development of enormous companies, and these absorb all the engineers, and the man who in England would be a small contractor is a member of the staff of a large concern. It would be exceedingly difficult for an electrical firm to begin business on this principle in England now. We believe the Westinghouse Company are going to try, and we wish them every success, and hope they will not only help to develop the electrical industry here, but that they will also show us how to do business on the wholesale interchangeable principle.

The consulting engineer seems to be non-existent in America, and we believe this is a point of great importance. In lighting a town here, for instance, the contractor, or the various contractors, are naturally at the mercy of the consulting engineer. The consulting engineer may be in a position to keep the contractor in order through his superior knowledge, but in many cases he is a drawback. Very often he has never had any practical experience, and has simply pushed himself forward by a judicious form of advertising. If electric work were more centralised, so that there were only a few large companies, those of the present consulting engineers who are really men of practical knowledge and experience would be employed by the companies, and the rest would perhaps be able to find some work they could do to advantage. The consulting engineer is now in an anomalous position: he has power to control the contractor, but if the installation does not work properly the blame is somehow or other generally thrown on the contractor. If it goes well the consulting engineer probably reads a paper on it, and is retained by the next town requiring lighting plant.

The American attitude towards science is radically different from ours. In this country we have too much respect for what is called "pure science." The measure of value of science is its immediate or probable future applicability to useful purposes. It must be distinctly understood that by pure science we do not mean what many people loosely term theoretical knowledge. Theoretical knowledge has a value that cannot be underrated. It is not merely useful, it is indispensable. If a man investigates the composition of Sirius his results are of no practical value. His work may be extremely engrossing, and the account of his researches may be very interesting reading, but it cannot well be regarded as work of practical value. An investigation of the tides, on the other hand, is a different matter; it is immediately useful. Now if a man spent a large portion of his time in studying the composition of Sirius, and evolved a number of speculative theories about it, he would be made a member of a number of learned societies and would become a distinguished authority at once. If another man of equal ability spent the same time in examining the properties of various insulating materials under various practical conditions, and found out enough to help electrical engineers out of all the difficulties that are dimly seen in the future, he would remain a nobody unless he chanced to procure a patent; and a section of the public would infinitely prefer to intrust the care of the lighting of a town to the astronomer than to the insulation inventor, because the former would be considered a distinguished scientific man. The Americans perhaps go a little too far the other way in their idea of what an electrical engineer ought to be, but they judge a man by his practical success.

There is still another important difference between American and English practice. In America they really understand the subdivision of labour. In England the same man has often to design machinery, manage shops, look after correspondence, superintend outside installations, canvass for orders, and work up the business generally. This evil partly arises, of course, from our system of comparatively small companies. In America there is a staff for each of these departments. Here we do not experiment in a systematic way. Every maker of any importance should have a special experimental department with a special experimental staff. At present most people would regard all that as reckless extravagance. We think quite the reverse, as the experiments must be done some time or other, and they are done, but they are done on machinery which is already on order, and this is the most expensive way of making experiments.

The last point is that there seems to be some difference in the matter of "push." If the electrical business was carried out more on American lines, is it not likely that such branches as mining work, electrical tramways and railways, and motor work generally, would be farther forward than they are?

THE OPENING OF WESTERN CHINA.

The Chinese Government has just given another illustration of its way of looking at things, and of doing things, which to Western minds, which will not take the trouble to study all the circumstances, may seem strange and possibly stupid. When fully considered, however, it will be seen that this way is possibly, on the whole, the best which the conditions of things will admit. Some time ago we mentioned the arrangements which had been come to with Mr. Little about the navigation of the Upper Yang-tse, and we pointed out that these in no way lessened the rights of British subjects generally under the Chefoo Convention, and that probably some would take advantage of these rights. The Chinese Government evidently recognised this, and now they have proposed to Lord Salisbury to modify the terms of the Convention. As originally drawn up, it was provided that Chung-King, the principal commercial city in the province of Szechuen, was to be constituted a

Digitized by Google

treaty port, and thrown open to the residence of foreign merchants so soon as a foreign vessel should have succeeded in reaching it. Yet when Mr. Little and his company made arrangements for doing this, they bought up his vessel and stipulated that he should not make another attempt for at least ten years. They now propose to open Chung-King, which is the great emporium of the trade of Western China, at once to foreign trade and to the residence of foreign merchants, but still subject to the restriction that the navigation of the river by foreign vessels be not attempted for the same time as arranged with Mr. Little. This may seem a piece of fooling, for all goods will require to be carried by junks from Tchang, taking in many cases months to go up, and costing much for insurance, for the dangers of navigation are very considerable. No doubt, people in this part of the world will say, if the Chinese are really in earnest about the matter they ought at once to get steamers suited for the navigation of the rapids, but they forget that in this country vested interest and narrow prejudices hinder for a very long time many needed reforms. Let them therefore put themselves in the place of the Chinese Government, and they will see how necessary it is to have a transition period, in which the changes may be carried out gradually. During that time foreign merchants will have the right of residing in Chung-King, and they will have opportunities for studying the requirements of the wealthy province of Szechnen, with its population of about 70,000,000, and no doubt, notwithstanding the impediments to transport, will be able to do a considerable amount of trade. At the same time the various vested interests will be able to adapt themselves to the changed conditions, and especially the provincial governments to the very serious loss of revenue from *likin* duties which would arise if direct and easy communication could be established in British vessels between Tchang and Chung-King. The junk-owners and haulers who make their livelihood out of the present system of navigation would also be able to turn to other work, although in any case we do not anticipate that the change would be so rapid as to dispossess these for a considerable time, and many of them would no doubt find occupation in the steamers. We trust that Lord Salisbury will agree to what seem to us to be reasonable proposals, and that opportunities will be afforded to our merchants of making themselves acquainted with the requirements of an immense population. If good use be made of their opportunities, we doubt not but that at the end of the transition period proper arrangements will be made for improved transport, and thus an immense outlet be afforded to British goods.

WORDS AS TRADE MARKS.

There is an increasing desire in the commercial world to have words instead of devices as trade marks. There are strong reasons for this departure. Words are more easily brought to the notice of the public and more easily recollected by them than devices, and some newspapers and periodicals object to advertisements containing anything beyond type.

The Patents and Trade Marks Acts, 1883 and 1888, point out what are the essential particulars of a trade mark, and particularly mention, sec. 64:—"(*d*) An invented word or words, or (*e*) A word or words having no reference to the character or quality of the goods and not being a geographical name."

This section has no reference to marks in use before August, 1875, technically known as "old marks." Old marks consisting of words are not rendered invalid because they transgress the above definition. The real object of a trade mark is to identify the goods of a particular manufacturer.

Words as trade marks possess certain disadvantages. The trade mark may have some connection with a patent, in which case the trade mark is of little or no avail after the expiration of the patent. The courts will not sanction the use of a trade mark which in any way tends to lengthen the monopoly of Letters Patent. To show the length to which the courts, here and also in the United States of America, have gone, we need only refer to the cases of the Wheeler and Wilson sewing machine and the Singer sewing machine. It was held in each case that, where a machine has acquired a name, other persons can, after the patent has expired, construct the machine and call it by that name; but such other persons may not place on such machines any mark which would lead the public to suppose that they were made by the original manufacturers. Independently of patents, we can state another objection to words as trade marks. The word may not be descriptive of the article at the date of registration, but it may subsequently become so. There has been no decision on this point, but any rights in the word will be very limited. To illustrate our meaning, a chemical manufacturer brings out a new compound (not protected by a patent), and for which the true chemical name is (say) methyl-diphenylamine, $C_6H_5NCH_3,C_6H_5$. He christens this "roslyn," registers the word "roslyn" as a trade mark, and then introduces the article into the market. It will be seen that this is a perfectly good trade mark. It is an invented word, and, at the date of registration, not descriptive. It would, of course, have been impossible for him to register the word "methyl-diphenylamine," as that is descriptive. In the ordinary course of events the manufacturer advertises the existence of the article, and after a few years the word "roslyn" becomes the popular equivalent of the more technical word "methyl-diphenylamine." Under these circumstances can it be supposed that the chemical manufacturer has the exclusive right to the word "roslyn," which word he has invented? In all probability it will be found that in his advertisements and trade lists he has used the word "roslyn" to describe the article, and not as a trade mark to identify his make from that of other manufacturers.

On this will depend the extent of his rights. If, as a fact, the word "roslyn" represents his manufacture, and his manufacture only, no other person will be allowed to make use of the word in advertisements or price lists. If, on the other hand, the word has, since registration, become descriptive of the article itself, other manufacturers would be entitled to make use of the word to describe the article; such other manufacturers could not, however, use the word as a trade mark. In this latter case the owner of the trade mark has very narrow rights. In another column will be found a report of a case of Barlow and Jones *v.* Johnson & Co. The case had reference to the word "Osman," which the defendants contended was descriptive of the particular article, and that there was no other word than "Osman" to represent that article.

Mr. Justice Chitty, however, held that the word "Osman" was not descriptive of a new article, and that it represented the plaintiffs' manufacture only; and he thereby deprived the public of a legal decision on a subject of great importance to the commercial world. If words as trade marks lead to inconsistent results, the time will not be far distant when words will no longer be available for registration except in the case of a firm's name.

THE LATE WILLIAM HENRY SNELL.

It is with great regret that we have to announce the death of Mr. William Henry Snell, the editor of the *Electrician*, which took place on the 5th inst., in the thirty-second year of his age. Mr. Snell was born at Tiverton, in Devonshire, on the 6th of November, 1858, and commenced life as a science teacher in his native town. He afterwards studied at the School of Electrical Engineering, Hanover Square, London, and from there he went to be chief electrician to the Cunard Steamship Company. He was subsequently a sub-editor on this journal, and his services were most valuable. In 1886 he joined the staff of the *Electrician*, and in the following year became editor of that journal. He was a man of great abilities and an incessant worker, and his minute knowledge of the various branches of science that he had to deal with was extraordinary. Those who knew him privately have lost a friend such as can ill be spared, and a man who was otherwise worth knowing on account of his general ability and information. He was one of the first to discuss alternating currents so as to make his work intelligible to non-mathematical readers, and had also written papers on distribution and other matters. He was also well known as one of the co-patentees of the Kapp and Snell transformers. An editor, however, is better known as a sort of embodiment of his paper, and all readers of the *Electrician*, whether they knew him personally or not, will feel the loss of his individuality.

THE LATE SIR PETER COATS.

By the death of Sir Peter Coats, which occurred at Algiers on Sunday last, in his eighty-second year, Paisley has lost one of its most esteemed citizens.

Sir Peter was born in Paisley on the 18th of July, 1808. His father, Mr. James Coats, was the founder of the great thread firm of Messrs. J. & P. Coats. When the firm was first established it engaged in the production of textile goods, but in the year 1824 its attention was turned to the manufacture of thread, which ultimately became its sole business. The sons of James Coats served their apprenticeships as engineers, and no doubt this laid the foundation of the success which attended their work, as they were thus able to take advantage of all the improvements which were made in machinery. The three sons—James, Peter, and Thomas—were all partners, and the business very soon became largely developed. On the death of their father, in 1857, the management fell upon Peter and Thomas, and the trade rapidly became almost world wide. Addition after addition had to be made to the works, until at the present time they form a group of buildings in which employment is found for 6,000 people. But even the immense works at Paisley were soon found insufficient to meet the demands of the firm's trade, and equally large works were started in America, so as to leave the Scotch works free to supply the home and continental trade. So much has the thread trade been concentrated that it may be said that a very few firms practically have a monopoly of it.

Sir Peter and his firm took a high view of their social duties, and devoted large sums to the improvement of the town of Paisley and the elevation of its inhabitants. The work with which Sir Peter's name is most likely to be connected was his gift of the Free Library and Museum Buildings, costing, with the site, about £18,000. In April, 1871, the library and museum were formally opened, and since that time they have been of the greatest possible advantage to the people of Paisley. Mr. Coats received the honour of knighthood in 1869. About twelve years ago Sir Peter bought the estate of Auchendrane, in Ayrshire, and his last years have been chiefly spent there and in Algiers.

THE LATE MR. ALAN BREBNER.

Our readers will regret to hear of the death of Mr. Alan Brebner, C.E., of the firm of Messrs. D. & T. Stevenson, civil engineers, Edinburgh, whose name has come before the public rather prominently recently in connection with the proposed Forth and Clyde Canal. Mr. Brebner had been connected with the firm of Messrs. Stevenson for a long time, first as a pupil, then as resident engineer on works, and latterly as a member of the firm. Before beginning work as a civil engineer he had served his apprenticeship as a mason, and thus laid a good practical foundation for his after work. In early life Mr. Brebner had considerable experience on railway work, chiefly in Fifeshire. Thereafter he returned to Messrs. Stevenson's employment, and was connected with the design and construction of many important works, especially those relating to harbour and lighthouse construction, and river improvement. He paid special attention to lighthouse apparatus, and devised several important improvements, and on the subject of lighthouses generally he was considered one of the foremost authorities. As a Parliamentary and legal witness he always gave his evidence in a clear and concise manner, and he spared no pains in making himself acquainted with the details of the case in hand. He was not much given to writing on professional topics, but the few papers he has left show a thorough grasp of the subject under discussion, and a clear method of expressing his views. He was gifted with a most retentive memory, and was an expert in all engineering calculations. Mr. Brebner was in his usual health until about a month ago, when he was attacked with hemorrhage, and he died somewhat suddenly on the 5th inst. He was in his sixty-fourth year, and leaves a widow and family. Of a quiet and reserved disposition he seldom came prominently before the public, but he made a large number of personal and professional friends to whom his death will be a matter of deep regret.

Letters to the Editor.

THEN AND NOW.

To the Editor of "Industries."

Sir,—Your special account of the Forth Bridge affords a most excellent idea of this enterprise from an engineering point of view, but its advantages to the ordinary traveller have not been made so evident. Though now resident in London I used formerly to live in Edinburgh, and the journey to and from Dundee and Aberdeen almost baffles description under the old state of affairs. There were two ferries to cross, one between Granton and Burntisland, and the other between Tayport and Broughty Ferry. The first, I think, is about three miles, and the second about one mile, but the delays occasioned were vexing to the soul. On one day, some six years ago, after the old Tay Bridge had broken down, and before the new Tay Bridge had been erected, I started from Aberdeen early in the morning to keep an important engagement in Edinburgh. The train kept very good time till we got to Broughty Ferry. On reaching that spot it was discovered that one of the ferry boats was laid up for repairs, and that the other had burst one of the steam pipes leading to the boiler. The result was that none of the passengers could progress on their journey. They wired to Dundee for a tug, but would or could not inform us when it would arrive, and we had to shiver in a bitter east wind on the pier in the month of February for, I think, some two hours. When we had crossed Fife the connection was, of course, lost at the Burntisland Ferry.

Digitized by Google

Altogether the run from Aberdeen to Edinburgh took about as long as the express train between Edinburgh and London.

All the trains from Fife to Edinburgh used to be as notoriously late as are those of the South-Eastern here. All this is now done away with, and local travellers have reason to congratulate themselves on the engineering enterprise of the present century.

I am also well acquainted with the usual Queensferry passage, which seems to have but slightly altered for many a long day, with the exception that a steamer took passengers across instead of a pinnace. The first chapter of Scott's "Antiquary" gives an account of how Lovel and Mr. Oldbuck had, firstly, difficulties with the coach from Edinburgh to South Queensferry, and how they had to dine at the Hawes Inn, which still exists, mainly depending upon cyclists. The date of the story is 1816, but it applies very considerably to the routine of a dozen years ago, only that then the coach was put bodily on board the ferry boat on its way to Dunfermline.

The new way of getting north will prove a boon, more to the Scotch on the North British lines, than to those who are going from London to Aberdeen, who have hitherto gone by Perth.

Yours, &c.,

A Scot in London.

BLASTING GELATINE PATENTS.

To the Editor of "Industries."

Sir,—Some statements made by Mr. MacRoberts in a paper read the other day before the Glasgow Section of the Society of Chemical Industry are instructive, as indicating that the fact of a patent having been granted has a deterring effect upon would-be imitators even after its expiration. He said the only firm making blasting gelatine was the Nobel's Explosives, and, though the patents expired last year, any competition was unlikely. He gave as a reason that the difficulty of obtaining a suitable site, the difficulties with the local authorities, with the Home Office, and, lastly, the difficulty of obtaining suitable technical management, made it improbable that the monopoly would be disturbed. The reasons adduced are weighty, but they are not conclusive. The obstacles referred to have been overcome by the Nobel Company, and, that being so, they could also be surmounted by any other company. If, therefore, Mr. MacRoberts' opinion that there will be no competition proves to be correct, the cause is rather to be found in the fact that the protection afforded by the patent has allowed the company to obtain such a firm hold of the market that a newcomer could not venture to oppose them. This should prove encouraging to other owners of patents about to expire.

Yours, &c.,

Patentee.

Newcastle-on-Tyne, 8th March, 1890.

LOCOMOTIVE PRACTICE.

To the Editor of "Industries."

Sir,—I find in your American contemporary, the *National Locomotive and Car Builder*, a statement the object of which is to show that English locomotives are far more expensive than those made in America. It is asserted that "a British locomotive building company, noted for the fine equipment of tools used and the advanced system of production followed, built two hundred locomotives last year, while employing on an average 2,500 workmen; a well-known American firm in the same time built three hundred locomotives while employing 1,400 workmen." It would have been far more satisfactory if we had been told the names of the firms, so that the figures given might be tested, but accepting them without question, it appears on the face of it that the American paper has not discovered the proper application of the facts. Dearness is purely a relative term, and a locomotive at a certain price may in the long run be more expensive than one of which the prime cost is 50 per cent. higher. The true deduction to be made from the foregoing statement is, that the English locomotive, upon which far more work has been expended, is the superior article.

Yours, &c.,

Loco.

THE STEEL OF THE FORTH BRIDGE.

To the Editor of "Industries."

Sir,—As some few thousand tons of that part of the steel that Sir John Fowler told the assembled guests at the recent inaugural ceremony, "had come from dear little Wales," were manufactured under my management, you will perhaps kindly allow me to make a few observations on the nature of the material that the inspecting engineers call throughout their final report just presented to Parliament "Siemens-Martin" steel.

In a general sense it matters little what name is given to a material that has amply proved its excellence by successfully undergoing the most searching and rigorous tests, and it is besides quite a common thing to designate open-hearth steel of any kind as "Siemens-Martin." Still, in these days, when a mere change in the position of the tuyeres in the Bessemer converter has been found so to modify the conditions of manufacture as to constitute a new process, it will not be thought hypercritical to distinguish between "Siemens-Martin" steel properly so called and "Siemens" steel pure and simple, which, as a matter of fact, is what Sir John Fowler referred to.

In the earlier, or "Siemens-Martin" process, malleable iron, wrought scrap, or scrap steel is melted in a bath of pig iron, from which the impurities are eliminated solely by the action of the flame and the addition of spiegel or ferro-manganese. Wrought metal, or steel scrap, is an essential element of the process, and no ore is used. In the "Siemens" process, on the other hand, a much larger relative quantity of pig iron is employed, and, although scrap is also generally worked up, the process can very well go on without it. Then, again, the impurities are driven out from the pig iron by the addition to the bath of a properly selected iron ore, which becomes reduced, whilst its oxygen carries away the carbon and assists in the formation of a siliceous slag. Both processes require Mushet's addition of ferro-manganese at the end, a common need of most steel-making operations. It will require little further explanation to show that the "Siemens" process lends itself more readily than the "Siemens-Martin" does to the continued production of large quantities of a high-class material of uniform nature, as pig iron and iron ore of the necessary quality can readily be obtained in any quantity, whereas wrought iron scrap and scrap steel are always difficult to procure when the amount needed is large.

At a time when not Britain alone, but the entire world, rejoices over the accomplishment of one of the greatest feats of engineering skill that dignifies the human race, it may not be inopportune to call to mind that it was at the Landore Steel Works that those methods were perfected which have furnished 51,000 tons of suitable material to build the giant structure that now spans the Forth. May its endurance for many centuries keep the name of Sir William Siemens in grateful memory, even as the design and construction of the bridge already ensure this meed of fame for the names of Fowler, Baker, and Arrol.

Yours, &c.,

F. J. R. Carulla.

Derby, 8th March, 1890.

Legal Proceedings.

BARLOW AND JONES (LIMITED) *v.* JOHNSON AND CO.

This case related to a trade mark, and occupied seven days before Mr. Justice Chitty. The plaintiffs and defendants were manufacturers and sellers, at Manchester, of Turkish towels. The plaintiffs claimed the exclusive user of the term "Osman" in connection with such towels. The defendants contended that the word was descriptive of a new article, that it was common to the trade, and that the plaintiffs could have no exclusive monopoly in the word.

Mr. Justice Chitty said that it appeared that the plaintiffs in 1879 commenced to make a superior quality of Turkish towels possessing a greater power of absorption than any hitherto introduced, and that in 1886 they registered their label as a trade mark under the Patents, &c., Act, 1883, bearing upon it the term "Osman," and also the head of Osman Pasha. The label thus registered had been from the commencement used by the plaintiffs for the special goods sold under it. To go through the voluminous evidence produced upon this trial would be an impossibility. He should therefore merely state the result of such evidence, and that was that the name "Osman" in reference to Turkish towels denoted in the market goods of the plaintiffs' manufacture, and had no other meaning. The defendants, however, said that the plaintiffs' title to the name "Osman" must depend on their right as existing at the date of registration (as was admitted), and that the plaintiffs had no right to the name, because the law was that if a man produced or invented a new article of manufacture, and gave it a new name by which it became known in the market, the name became *publici juris* and could not afterwards be recaptured and appropriated for exclusive use. The defendants said that where an article for which a patent was obtained became known by a name connected with the patent, exclusive property in the name was not permitted because there was no other designation for the article, and to hold otherwise would operate as an elongation of the patentee's term of monopoly under the patent. In support of this view the defendants relied on the Wheeler & Wilson sewing machine case and the "Gem" gun case. These authorities were not applicable to the present case. The plaintiffs never had any monopoly. It was open to the whole trade to make precisely similar goods and call them by any name they pleased. The defendants, however, also urged that where a new article was produced not under a patent and given a new name by which it became known, and which, when examined, was descriptive of the article, the name could not be appropriated by means of registration or by any other means. Cases were cited in support of that proposition, but the *ratio decidendi* of these cases was that the word in question was or had become descriptive of the new article with which it was connected. He, however, found upon the facts that the Turkish towels manufactured by the plaintiffs were not "new articles" in the sense contended for. All that the plaintiffs had done was to make certain improvements in the quality of the towels, and to this superior quality of towels they gave the name "Osman" by means of labels affixed to the goods. The name denoted nothing more than that the articles were of a particular quality and that the plaintiffs were the makers. The question whether the name denoted the article or the particular manufacture was a question of fact. In the present case he held upon the evidence that the term denoted the manufacture. Therefore the questions of law contended for by the defendants did not arise. His Lordship then dealt at length with the other arguments of the defendants, and gave judgment for the plaintiffs, and granted a perpetual injunction restraining the defendants from using the word "Osman" in connection with Turkish towels.

SHIPBUILDING NOTES.

On the 6th inst. Messrs. Short Bros., Pallion, launched the steel screw steamer "Enchantress," built to the order of Messrs. Taylor & Sanderson, Sunderland. The vessel is of the spar-deck type, with cellular double bottom and six water-tight bulkheads. The principal dimensions are: Length between perpendiculars, 292ft.; breadth, moulded, 40ft.; depth of hold, 27ft. 6in. The deck machinery is specially complete, and is provided with steam from a large multitubular boiler placed on deck. The vessel will be provided with quadruple expansion engines by Messrs. Allan & Co., Scotia Engine Works, Sunderland.

On the 6th inst. Messrs. J. L. Thompson & Sons, of North Sands, Sunderland, launched the steel steamer "Poh Ling," which has been built to the order of the China Shippers' Mutual Steam Navigation Company. The principal dimensions are: Length between perpendiculars, 378ft.; breadth, moulded, 41ft. 6in.; depth of hold, 25ft. 3in.; and measurement capacity about 5,000 tons. In every respect the vessel is most completely fitted and finished for the tea trade. At each hatch double derricks are fitted, and the cargo arrangements generally are specially designed for rapid handling of cargo. The engines are of the triple expansion type and indicate 2,800 h.p. The cylinders are 32in., 49in. and 77in. diameter, by 48in. stroke. The engines and boilers have been constructed by Mr. John Dickinson, Palmer's Hill Engine Works.

On the 7th inst. Messrs. Richardson, Duck, & Co. launched from their yard at Stockton-on-Tees a steel screw steamer named the "Montebello," of the following dimensions:—Length over all, 287ft.; breadth, extreme, 35ft.; depth, moulded to awning deck, 25ft. 9in. This steamer has been built to the order of Messrs. Thos. Wilson, Sons, & Co., of Hull, and is intended for their passenger trade between Hull and Norway. The awning deck extends fore and aft, and on it a large deck-house has been erected amidships containing dining saloon for 70 first-class passengers, &c. She will be engined by Messrs. Amos & Smith, of Hull.

On the 7th inst. Messrs. Bartram, Haswell, & Co., South Dock, Sunderland, launched the steel screw steamer "Benedick," built to the order of Messrs. C. Howard & Son, London. The vessel has a raised quarter-deck, partial awning deck forward of engine-room, full poop aft, cellular double bottom, and web frames and intercostals. The principal dimensions are: Length between perpendiculars, 300ft.; breadth, moulded, 39ft.; depth of hold, 21ft. 7¼in.; and gross register, 2,460 tons. The deck machinery includes six steam winches, Davis's hand and steam steering gear, Hastie's steering gear aft, &c. The vessel will be schooner rigged, with telescopic masts to suit the bridges of the Manchester Ship Canal. The engines and boilers have been contributed by Mr. John Dickinson, Palmer's Hill Engine Works, Sunderland.

On the 8th inst. the Strand Shipbuilding Company, North Sands, Sunderland, launched the steel screw steamer "Oxus," built to the order of the Oxus Steamship Company, of London. The principal dimensions are: Length between perpendiculars, 216ft.; breadth, moulded, 28ft. 3in.; depth of hold, 18ft; and tonnage, about 910 tons gross register.

On the 8th inst. Messrs. William Doxford & Sons launched from their yard at Pallion a steel steamer, built to the order of Messrs. William Ross & Co., of East India Avenue, London. Its dimensions are: Length, 365ft.; breath, extreme, 44ft.; depth, moulded, 30ft. The engines are of the triple expansion three-crank type, by Messrs. Doxford; the cylinders are 27in., 44in., and 72in. in diameter, by 48in. stroke. They are supplied with high-pressure steam from two double-ended boilers. She is fitted throughout with electric light by Messrs. J. H. Holmes & Co., Newcastle; steering gear amidships by Messrs. Bow McLachlan & Co., Paisley; screw gear aft by Crawford Brothers, Monkwearmouth; steam windlass, by Messrs. Emerson Walker & Thompson Brothers, Gateshead; and five 7in. by 12in. winches, by Welford Brothers, of Pallion.

On the 8th inst. Messrs. Laird Brothers, Birkenhead, launched from their works the torpedo gunboat "Almirante Condel" for the Chilian Government, a sister vessel in every respect to the "Almirante Lynch," which was launched from the same yard on the 10th ult. These vessels are an enlarged form of the well-known "Rattlesnake" of our own navy. They have a length over all of 240ft., with 27ft. 6in. beam, and a maximum draught of 9ft. to 10ft. They will be fitted with two pairs of triple expansion surface condensing engines, with four boilers of the locomotive type, and when working under forced draught will be capable of exerting 4,500 h.p., with which a speed of 21 knots is expected.

On the 8th inst. there was launched from the yard of the Tyne Iron Shipbuilding Company, Limited, of Willington-Quay-on-Tyne, a steel screw steamer, which has been built to the order of Messrs. Kinghorn Brothers, of Liverpool, agents for the owners, Messrs. Wm. Howard Smith & Sons, Limited, of Melbourne. The vessel is of the following dimensions, viz.:—Length, 300ft.; breadth, 41ft.; and depth, 23ft. She has water ballast right fore and aft on the cellular system, and will be fitted with all modern improvements for the rapid loading and discharging of cargo. The engines are to be supplied by Messrs. Wigham Richardson & Co., and are of the triple expansion type; the cylinders are 23in., 37in., and 62in. in diameter, by 42in. stroke. Steam is supplied by two large boilers constructed throughout of steel. On leaving the ways the vessel was named the "Time."

SAYER'S PATENT AIR PROPELLERS AND BLOWERS.

CONSTRUCTED BY MESSRS. BENNETT & SAYER, ENGINEERS, DERBY.

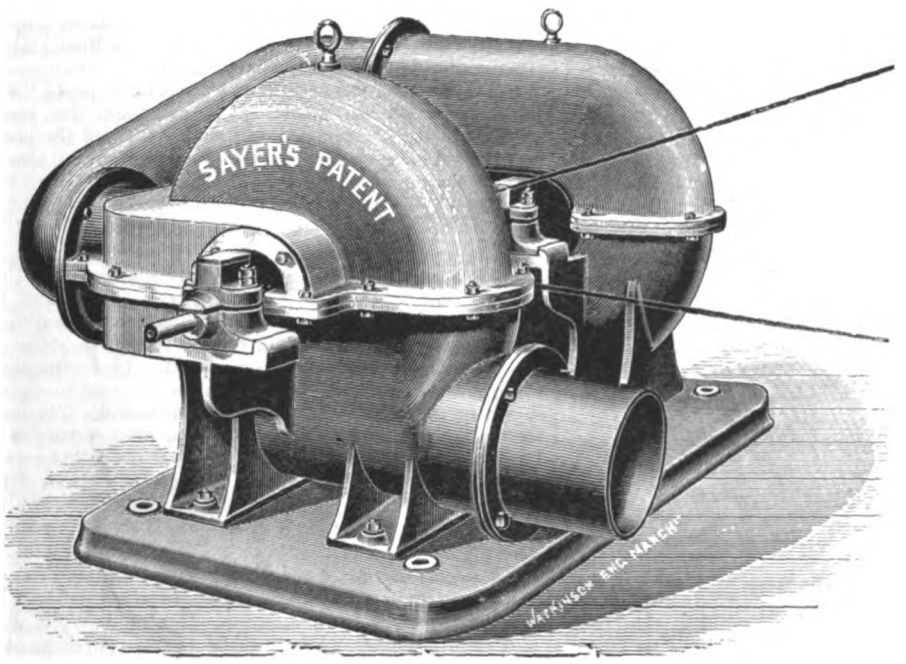

FIG. 1.—COMPOUND HIGH-PRESSURE FAN.

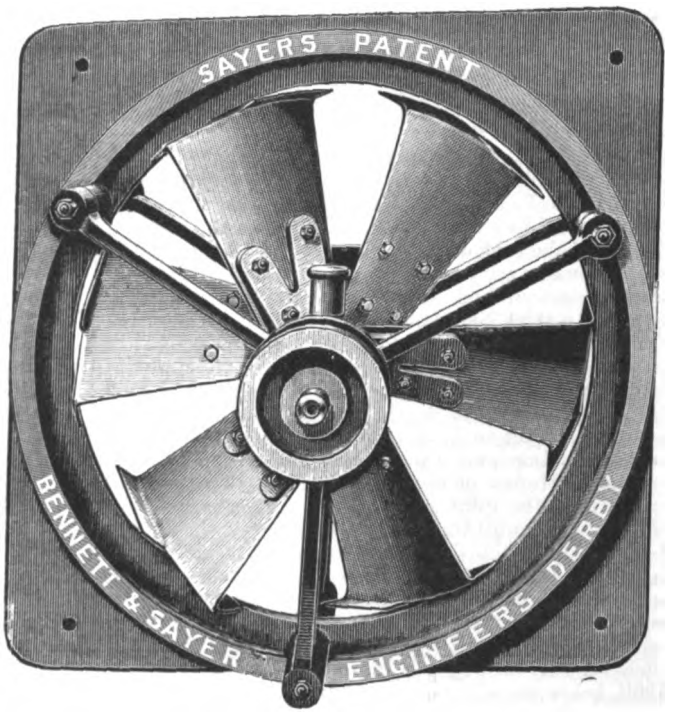

FIG. 2.—REVERSIBLE AIR PROPELLER.

SAYER'S PATENT AIR PROPELLERS AND BLOWERS.

IN Fig. 1 we show Sayer's patent compound high pressure fan, which is intended for use in iron foundries. In addition to its use for the foundry cupola, it is found efficient for sand-blast machines, pneumatic despatch, and for forcing air through long distances in pipes. These fans give 25in. water pressure at very moderate speeds.

In Fig. 2 we illustrate Sayer's patent reversible air propeller. The special point of the construction of this fan is that it can be used for forcing air in either direction with equal efficiency without any rearrangement of parts.

Fig. 3 shows one of the smaller sizes of Sayer's patent blast wheels, with one steel side plate removed to show its construction. A blast wheel similar to the one illustrated, 30in. in diameter, will pass, through a 15in. outlet, 15,000 cubic feet of air per minute, at a speed of only 1,000 revolutions per minute.

The makers of these various types of blowers are Messrs. Bennett and Sayer, engineers, Derby.

THE INSTITUTION OF CIVIL ENGINEERS.

AT the fourteenth ordinary meeting of the Session, on Tuesday, the 4th inst., Mr. Berkley, Vice-President, in the chair, three papers were read on Railway Bridges:—

I.—THE HAWKESBURY BRIDGE, NEW SOUTH WALES, by Mr. C. O. Burge, M.Inst.C.E.

The railway system of New South Wales had hitherto consisted of two separated divisions—the one starting from Sydney and branching thence in a westerly, southerly, and south-westerly direction, while the other originated at Newcastle, on the sea coast, about 100 miles north of Sydney, and communicated with the northern part of the Colony and with Queensland. The Hawkesbury Bridge was situated upon the connecting link of railway which was designed to unite these two systems. It crossed the main channel of the Hawkesbury between Long Island and Mullet Head, at a point where the channel had a width of about 2,800ft., and a maximum depth of 77ft., while its bed consisted of a deposit of mud extending to a depth varying from 60ft. to 170ft. below high-water mark, and overlying the sand. For the construction of this difficult work, the Colonial Government invited tenders accompanied by competitive designs, and took steps to make the competition world-wide. A committee, consisting of Mr. W. H. Barlow, Past President Inst.C.E., Mr. G. Berkley, Vice-President Inst.C.E., and Captain Douglas Galton, R.E., Assoc.Inst.C.E., was appointed to adjudicate on the tenders; and when the report of this committee had been supplemented by others from Sir John Fowler, Past President Inst.C.E., and Mr. John Whitton, M.Inst.C.E., Engineer-in-Chief for Railways, New South Wales, it was finally decided to accept the tender of the Union Bridge Company, of New York, who undertook to complete the bridge within two years and a half, for the sum of £327,000. The accepted design consisted of seven spans of 415ft. (from centre to centre of the piers), the foundations being carried down in steel caissons filled with concrete, while the upper portions of the piers and the whole of the abutments were of masonry. The girders were formed of built steel compression members, and solid steel eye-bar tension-rods, all the connections being made by steel pins. The cross-girders and rail-bearers were of riveted steel plate. The two main girders of each span were 410ft. long from end pin to end pin, and 58ft. deep at the centre, and were placed 28ft. apart from centre to centre, the bridge carrying two lines of railway. In the execution of the foundations, it was found very difficult to sink the caissons in a truly vertical position through the great depth of mud that had to be penetrated before the sand could be reached. The tendency of the caisson to assume an inclined position, and to draw away from its true place during the process of sinking, gave rise to a great deal of trouble and delay, and in some cases could not be entirely overcome; and the author was of opinion that this difficulty was in great measure due to the form in which the caissons were constructed. In plan, the caisson formed a rectangle with rounded ends, its length, transversely to the bridge, being 48ft., while its outside width was 20ft. The outer shell of the caisson, having this contour, formed a vertical prism for the greater portion of its height; but in the lowest 20ft., the walls were splayed 2ft. outwards at the base by inclining them at a batter of one in ten at the sides, and also at the rounded ends. Each caisson contained three circular dredging wells, 8ft. in diameter, placed along its axis at distances of 14ft. from centre to centre, the wells being splayed outward at the base in conical form, so as to meet the outer shell, and to come to a cutting edge at the periphery of the caisson and also between the wells. The lower part of the caisson was built on shore, and, being temporarily fitted with a false bottom, was floated out and sunk to the bed of the river. The space between the wells and the outer skin was then loaded with concrete, and the caisson was sunk through the mud by dredging the material from the bottom of the three wells. If the caisson showed any tendency to cant transversely to the bridge, it could be righted by dredging one or the other of the wells in advance of the remainder; but when it canted transversely to the axis of the caisson, the central position of the well precluded the use of any such means of righting it. It was also believed that the

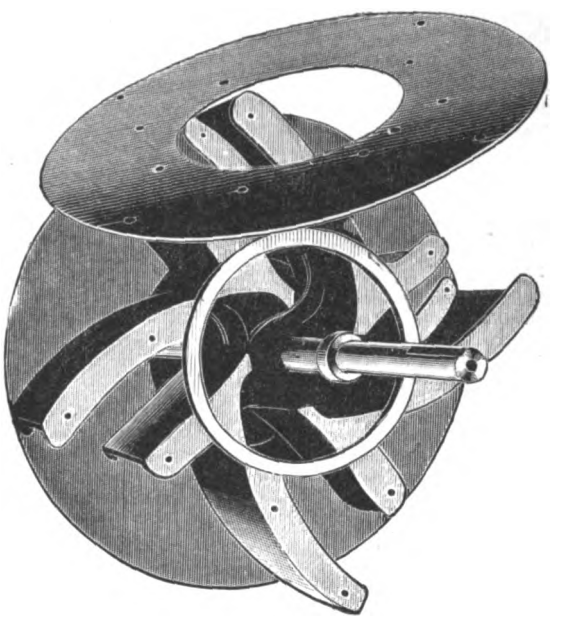

FIG. 3.—BLAST WHEEL.

splayed form given to the base of the caisson enhanced the tendency to cant over, as the sinking of the splayed shoe would leave around the walls of the upper portion an empty space, which would afterwards become filled up in an irregular manner, depending upon the consistency of the mud. For the work of erecting the main-girders, a pontoon was constructed of sufficient size and stability to carry a complete span of the superstructure elevated above the deck upon staging high enough to command the piers, whose summit was 40ft. above high-water, the range of tide being 7ft. At a convenient point on the shore, a gridiron was built at a distance of about half a mile from the bridge, and on this gridiron the pontoon was scuttled and allowed to remain, while the steelwork of a complete span was put together upon the top of the elevated staging above the deck. For the voyage of this craft out to the bridge, a favourable conjunction of tide and weather was selected, and, the scuttling valves of the pontoon having been closed at low-water, the vessel floated off the gridiron at the rise of the tide, and was warped out to the bridge by 6in. hawsers worked by steam windlasses, the operation being facilitated by the assistance of steam-tugs and by the flow of the tide. At the top of the tide, the pontoon was in place between the piers, the ends of the main-girders being then a few inches above the bearings on the piers, and the vessel, being moored in this position, was allowed to fall with the ebbing tide until it left the

Digitized by Google

girders supported upon the piers. In some cases the process was hastened by partially scuttling the pontoon. The author described the numerous vicissitudes of the voyage, which was repeated in similar manner for each span, and also the endeavours that were made to correct or to remedy the canting of the caissons. It was worthy of remark that although the successful tender was made by an American firm, yet the whole of the steel and ironwork was provided and manufactured in the United Kingdom, excepting only the swelled heads of the eye-bars.

II.—The Construction of the Dufferin Bridge over the Ganges at Benares, by Mr. F. T. G. Walton, C.I.E., M.Inst.C.E.

The Dufferin Bridge was constructed by the Oude and Rohilkund Railway Company, in order to connect their line with the East Indian Railway, and was the fourth bridge erected by the same company across the Ganges. The site of the bridge was immediately below the ancient city of Benares, where the river was confined in a comparatively narrow and deep channel, the left bank being formed of a thick bed of clay which resisted the abrasion of the stream, and which extended below the river bed as far as the middle of the channel, while the remainder of the bed and the right bank were formed entirely of sand extending to a great depth. In the rainy season the river was subject to floods rising 50ft. above lowest river level, and submerging the district on the right bank for a distance of five or six miles inland. But from the cessation of the rains in October the stream generally fell gradually, until the recommencement of the rains in June. During the dry season the current lessened by degrees, until its velocity was not more than one mile an hour, and the channel then silted up considerably; but during the rains the velocity of the current was occasionally fifteen miles an hour, and the bed was sometimes scoured to a depth of 70ft. below low-water, or 120ft. below flood-level. The bridge consisted of seven spans of 356ft., and nine of 114ft. (from centre to centre), and was built for a single line of 5ft. 6in. gauge. The railway was carried between the main girders of the large spans, and on the top of the girders of the smaller spans. The height from low-water to rail level was 79ft., and the clearance under the main spans at highest flood was 25ft. A metalled road, 22ft. in width, was provided at rail-level, and was used for cart traffic between the passage of the trains. A footway, 5ft. wide, was carried on cantilevers outside the main-girders on each side. Both abutments were built as block-houses to contain troops for the military defence of the bridge. The river piers carrying the 356ft. spans were each founded on a single well of elliptical shape, 65ft. across the major axis, and 28ft. across the minor axis. For each well an iron caisson, of similar elliptical form, was provided, the height of the caisson varying from 10ft. to 50ft., according to the depth of water in which the pier had to be built. The caissons were constructed with three internal excavating chambers divided by cross walls 5ft. in thickness, and surrounded by the elliptical wall of caisson which was also 5ft. in thickness. The outer shell was vertical throughout, while the inner skin inclined inwards from the base at an angle of 45°, thus forming a cutting-edge which was strengthened by a cast-steel shoe 1½in. thick. Three of the piers were situated on, or very near to, the dry bank of the river, and these wells were sunk to a depth varying from 48ft. to 133ft. below low-water. The remaining four caissons were built on pontoons and lowered to the bed of the river; and were sunk by means of Bruce and Batho's dredgers worked from staging erected on the pontoons, the depth of these foundations varying from 62ft. to 141ft. below low-water. The wedge-shaped portion of each caisson, above the cutting-edge, was filled in with cement concrete; and above that height the space between the inner and the outer shells was filled with brickwork in mortar. Above the top of the caisson, the brick well and cross walls were carried up in similar elliptical form, and the work was bonded with the brickwork below by an iron crate of angle-bars contained within the thickness of the walls. In sinking through the great depths above mentioned, it was frequently found that the well exhibited a tendency to cant over in one direction or another; but this tendency was corrected without any great difficulty, and the wells were successfully got down in their true positions with no greater divergence than 6in. in any case. Two of the wells, when passing through a hard stratum, canted over considerably from the vertical. No. 6 was 4ft. 9in. out of perpendicular when 109ft. in the ground, and No. 7 was 5ft. 3in. out when 135ft. in the ground. To right these wells a weight of about 1,000 tons, in rails, was first brought on so as to cause the greatest pressure on the high side. The earth outside the well was then excavated, on the side towards which the well was leaning, leaving the slope of the excavation at 1 to 1. This slope was covered with wooden sleepers, on which rails were laid in the direction of the slope 6ft. apart. Again, on these rails were laid cross-sleepers close together, and the whole excavation was then filled in with bricks, forming a wedge-shaped mass which pressed continuously against the side of the well as it sank. In this way No. 6 was brought upright while sinking only 5ft. 8in., and No. 7 was righted in sinking 20ft. The main-girders were entirely of steel, the allowed working stress being 6½ tons per square inch. They were 355ft. 6in. in length, with a uniform depth of 35ft. 4¼in. The lattice-web consisted of vertical posts and inclined ties crossing three bays at an angle of 45°. The weight of a pair of main-girders was 491 tons, and of the complete span 746 tons. For the erection of these girders, the smaller girders for the 114ft. spans were used to form a temporary bridge of three spans extending across each opening, and carried upon two temporary piers consisting of twelve iron screw-piles driven into the bed of the river. The piles were braced together above water-level; but in some cases they were situated in 65ft. depth of water, and to ensure the stability of the temporary pier the group of piles was embedded in a raised mound of sand contained between walls of sand-bags. The cost of erecting one of the large spans was Rs. 57 per ton. The execution of the works gave employment to a large number of natives, as many as seven thousand having been employed at one time. The bridge was the joint design of Mr. Hederstedt, the Company's Chief Engineer, and Mr. Batho, their Consulting Engineer in England, Mr. W. H. Barlow, Past President Inst. C.E., having been consulted in the first discussion and arrangement of the design.

III.—The New Bridge of the London, Chatham, and Dover Railway Company over the Thames at Blackfriars, by Mr. G. E. W. Cruttwell, M.Inst.C.E.

The new bridge, which had been erected by the London, Chatham, and Dover Railway Company, across the Thames at Blackfriars, immediately alongside their older bridge, together with the new station in Queen Victoria Street, formed an important extension, which was long needed for the increasing traffic of the railway. The bridge was designed to carry, in all, seven lines of railway, and had a clear width of 81ft. between the parapets; but this width was increased to 123ft. at the northernmost span, where it was necessary to provide space for the platforms as well as for the lines of way. In consequence of the great width, and the occurrence of numerous cross-over roads upon the bridge, it was impossible to adhere to a construction like that of the older bridge, consisting of main girders rising above the rail-level; and it was considered preferable to adopt a series of arched ribs placed entirely beneath the rails. The bridge had five spans: the shore span on the Surrey side being 183ft.; the centre span and the Middlesex shore span, 185ft. each; and the second and fourth spans, 175ft. each; the lengths of the three middle spans being fixed so as to correspond with those of the old bridge alongside. The foundations of the abutments were carried down to a depth of about 25ft. below Trinity high-water, the work being executed within cofferdams composed of a single row of sheet-piles of sawn pitch-pine. The foundations of the river piers were all carried down to 46ft. below Trinity high-water, and were laid in the London clay, the depth below the river bed varying from 16½ft. to 23½ft. Piers Nos. 1, 2, and 3 were each founded upon three rectangular caissons spaced 6ft. apart; whilst for the long pier on the Middlesex side four caissons were required. Immediately above low-water level arches were turned across the 6ft. openings, and above these the piers were carried up solid. The caissons were about 30ft. by 30ft., and consisted of a single skin of wrought-iron varying from ½in. to $\frac{5}{16}$in. in thickness, stiffened by vertical angle- and tee-bars spaced at intervals of about 7ft., and also by temporary horizontal stiffeners. In each case the lower portion, or permanent caisson, was 21ft. in height, and above this a temporary caisson was carried up to a further height of 28ft., this portion being bolted to the permanent caisson and removed after the building of the pier was sufficiently advanced. For sinking the caissons a staging was erected around the side of each pier, and to regulate the descent each caisson was suspended from the staging at the four corners by wrought-iron rods 2¼in. in diameter. The rods were in lengths coupled together by pins, and the top length of each rod was cut with a square screw thread 2½in. in diameter, by which the caisson was lowered uniformly at the four corners, the nuts being simultaneously turned by four spanners coupled together. The silt and ballast were excavated down to the clay by Priestman's grabs worked by movable jib-cranes; and, as soon as the caissons had been sunk well into the clay, the water was pumped out, and the digging was continued in the dry. At first, this could only be done during low-water, and, as the tide rose, the water was admitted into the caisson; but as the caisson penetrated to a safer depth into the clay the time of working was extended, until, on reaching the full depth, the tide was kept out altogether, and the concrete work was then commenced. The permanent caissons were filled with concrete to within 4ft. of the top, and above this level the brickwork and granite facings of the piers were carried up for a few feet inside the temporary caisson. The latter was then removed, and the masonry of the piers was continued by tide work. The superstructure of the bridge consisted of a series of arched ribs of segmental form, having a rise of 18ft. 6in., and a depth of 4ft. 6in. At each end the bearing of the ribs was taken upon a cylindrical pin of wrought iron, 8in. in diameter, which rested in a semi-cylindrical socket formed in the bed-plate. The arched ribs had sufficient transverse stiffness in themselves, and there were no braced spandrels between them and the upper longitudinal girders carrying the floor of the bridge, which were simply supported upon the arched ribs by vertical posts. The longitudinal girders were fitted between the cross-girders which were riveted upon the tops of the posts, the joints being connected by cover-plates and also by the flat floor-plates, $\frac{11}{32}$in. in thickness, which were laid over the whole surface. The longitudinal member might therefore be considered as continuous, and was made so in order to counteract the effect of unequal loading of the various spans upon the piers and foundations of the bridge. The continuity was unbroken throughout the entire length of 987ft., the member being contained between abutments of sufficient stability to withstand the thrust due to any probable rise of temperature, while it was also tied back at each end to anchorages of sufficient stability to withstand contraction. The longitudinal member was riveted up at a temperature of 50° Fahr.; and before it was finally closed, observations were taken of its actual contraction when the thermometer stood at 26° Fahr. The contraction resulting from this fall of 24° was 2in., which corresponded nearly with the amount by which a length of 987ft. of iron should contract according to calculation. The joint engineers for the works were Mr. William Mills, of the London, Chatham, and Dover Company, and Messrs. J. Wolfe Barry and H. M. Brunel. The author of the paper was their resident engineer.

SAFETY IN ELECTRICAL DISTRIBUTION.

By James Swinburne.

I.

In these articles it is proposed to discuss the merits of various automatic safety devices, and to mention and suggest a few more, of which some are new.

By safety is meant safety from personal injury and safety from fire. And it is the intention to show that with reasonable precautions it is possible to render the electric light almost perfectly safe

Series Arc Circuits.—Take first the case of high tension series arc lighting. There have been numerous accidents in the States through arc circuits being badly insulated. Of course we may reasonably assume that the circuits are well insulated, at least, to begin with; but for a circuit to be safe it is not enough that the wires should be perfectly insulated; the public and the companies' servants should be protected against any accidents which might occur through the insulation breaking down anywhere.

Almost every arc lamp in the market has its framework in contact with the circuit. This is a reprehensible practice, and has been the cause of one or two accidents. It must be remembered, however, that the frame of an arc lamp will always tend to be at the same potential as its carbons, for the series and shunt circuits, as well as the rods, must be in connection with the circuit. It would add little to the expense of construction to insulate the frame with low insulations; but it would be exceedingly difficult to insulate the frame up to, say, a million megohms, so that the insulation might rank as part of the main circuit. By low insulation, in this article, I mean insulation suitable for low pressures of, say, 50 to 150 volts; by high insulation, I mean insulation fit for standing from 1,000 volts upwards. With the best insulation available in an arc lamp, the frame might be earthed, so that there would be no danger; but it is probable that the arc lamp insulations would always be giving out. It would, therefore, seem best to insulate the frame from the circuit with low insulation, such as strips and washers of insulating materials, which will, as a matter of fact, sooner or later, become dirty; but not to trust to the insulation. It is easier to highly insulate the frame of the lamp from the post, as there are fewer contacts to protect. The lamps themselves must still be regarded as weak points in the circuit.

Another weak point in the circuit is the dynamo itself. Minute leaks to earth in the dynamo may easily occur. Considerable care is generally taken in insulating the armature; but there is little reason why the field magnets should be series wound. Series wound arc light machines, each working on its own circuit, are survivals of the old ideas. Where one machine is used

Digitized by Google

alone it is difficult to find anything better, but in a station it is simpler to work all the arc lamps from one or two large machines in parallel. Electromotive forces of 2,000 to 4,000 volts are generally quite unnecessary, as 1,000 would be practically as economical in copper, and would give much less trouble by break-downs. In considering cost of leads, people are apt to forget the extra cost of insulation for higher pressures.

The large machines, being separately excited, need high insulation in their armatures only. As this method of arc lighting is not in use, it is not necessary to discuss it farther. Even if a number of high tension machines are used, each feeding its own series circuit, it is better to excite them separately, not only because it is easier to insulate the high tension circuits, but also because greater steadiness can be obtained, and a more perfect type of machine may be used. This arrangement has been adopted at Tilbury Docks by Messrs. Crompton & Co.

Returning to the question of safety of life. If the circuit is fully insulated throughout, a man touching the circuit cannot get an appreciable shock, as there is no complete circuit. To be dangerous, a circuit must be grounded somewhere else to make a circuit through a man. Thus even if the frames of the arc lamps form part of the circuits, an attendant, or a linesman belonging to another company, should feel nothing if he touches one. The accidents in the States could never occur without the greatest carelessness. Probably the circuits were never tested, but were taken as all right until a breakdown occurred—that is to say, as long as there was only one ground on each circuit, nothing was done in the way of repairing it. The result of such criminal carelessness would be that in a short time nine circuits out of ten would be earthed at one place each, and would be ready to kill anyone who touched an arc lamp.

As it needs an earth elsewhere to injure the man who touches an arc circuit, it can be made safe by arranging something to give the alarm, or to cut the circuit as soon as one leak occurs. The circuit is artificially earthed at the middle. Of course the actual middle of the circuit may be some miles off, so two high resistances are put across the circuit, and the middle is earthed. The earth connection is made through an electromagnet, and if any current passes, the electromagnet either puts out all the lights on the circuit instantly, or breaks the earth connection and rings an alarm. Suppose a man now touches the circuit somewhere, a current passes through him and back by the electromagnet. The electromagnet circuit is made with such a high resistance that only a harmless current can pass through the main, even under the 1,000 volts or so that represent half the electromotive force of the machine.

I have tried some experiments, which I hope soon to publish, on the current a man can take without serious discomfort. He can easily take a direct current of from a hundredth to a fiftieth of an ampere. In a 2,000 volt circuit, therefore, a safety cut-out with 20,000 ohms in its magnet circuit, and 40,000 ohms in the pair of resistances in shunt to the whole circuit, render it impossible for a man to get a serious shock. An automatic cut-out of low resistance might kill a man, even though it acted almost instantly. Condenser methods have been proposed, but they are no safer than high resistances, and do not act unless the earth contact is made suddenly, and are therefore not to be depended upon. The electromagnet may be arranged in several different ways. These will be more fully discussed in connection with incandescent distribution.

Danger from fire need not be separately considered in the case of arc circuits, as a system which is safe as to life is safe as to fire, for it takes two earths to cause a fire.

In places where overhead wires are used many troubles have arisen from telephone, telegraph, or other wires falling across electric light circuits. If the electric light circuit has been sufficiently insulated a wire falling across it should not come into metallic contact with it. On the other hand, if the insulation has been so bad as to have perished spontaneously, and to have left the wire bare, no automatic tell-tale will give warning till an earth is made. Immediately a telephone or other wire touches it, however, the electromagnet will prevent any damage.

A great many accidents have been reported in which the arc circuit broke and fell over other wires, making contact and doing damage. This seems impossible, for if an arc wire broke the machine would almost instantly lose its field, and there would be very little electromotive force available. Some arc machines will, however, give 120 volts on open circuit, due to the residual magnetism of their fields. Moreover, if the wires were insulated they might rest on other wires without necessarily short circuiting. If bare overhead wires or wires with only an apology for insulation are used in connection with separately excited dynamos, of course they will remain alive, even after breaking.

PRACTICAL WORKING OF THE ELECTRICAL SUBWAYS IN NEW YORK.

(*From our New York Correspondent.*)

At the meeting of the American Institution of Electrical Engineers, held in New York, on February 18th, Mr. Wm. Maver, Jun., electrician of the Subway Company, gave a description of the various systems adopted, with the results of the experience of the past year. The ideal system, as generally understood, he said, was a commodious tunnel, which would also provide for gas, water, and steam service. This had been dismissed as too expensive, the estimated cost being $430,000 per mile, or $30,000,000 for the entire city. Eight different systems of conduits had been adopted, experimentally or permanently.

Firstly, there is the Dorsett conduit, of asphalt concrete: the blocks are about 4ft. long, being moulded with 2½in. ducts. This is in a fair state of preservation. Then there are the zinc tube conduits, in which the tube is surrounded by hydraulic cement. It was expected that the zinc would corrode, leaving the cement tubes intact. Owing to the frail tube collapsing under slight pressure in construction, this plan has been abandoned. The sheet iron cement-lined pipe conduits are made in single or multiple tubes of two, four, six, or more ducts in 8ft. lengths. The tubes are connected with ball and socket joints. About 113 miles of these ducts have been laid, and it is expected more will be laid this year. About fifteen miles of creosoted wooden ducts have been laid, known as the Wyckoff conduit, and are made of logs bored out. Lead-covered telephone cables are placed in these, and the action of the creosote upon the lead is being carefully watched. After three years' use no apparent deterioration has taken place. The lead is alloyed with 3 per cent. of tin. The bulk of the subway conduits consists of wrought-iron pipe laid in hydraulic cement concrete. These pipes are 20ft. in length, and vary in diameter from 2in. to 3in. The thickness of the iron is ·217 of an inch. In laying these pipe conduits, the bottom of the trench is first levelled to the gradient; planks are then set against the side of the trench to sustain it. A layer of concrete is then laid and rammed in the bottom of the trench. On this is placed a row of iron pipes, next a layer of concrete, then another row of pipes, and so on, until the desired number of layers is attained. The number of pipes in a row depends upon the topography of the street and the location of existing gas and water pipes which it is desired to avoid; and the number of rows, upon the total number of pipes desired to be laid in a given subway. In order to add strength to the mass, and to protect the ducts from mechanical injury, the concrete is applied more thickly on the bottom, top, and sides of the subway than between the pipes. There is placed over all a 2in. yellow pine planking, heavily creosoted, to further protect the conduits against injury from picks, crowbars, &c., in the event of future excavations in the streets. The wrought-iron pipes are joined end to end by a coupling screw-joint with a tapering or vanishing thread. By the use of this form of thread, the rate of laying this pipe is increased 50 per cent. These tubes are delivered free from burrs, and have a smooth inner surface. The pipes are sometimes asphalted to prevent rusting, but should they in course of time rust, it is expected, as in the case of the zinc tubes, that the concrete will preserve the shape of the duct intact. There are close upon 550 miles of wrought-iron piping in the subways. The facility with which a pipe conduit conforms to the varying condition of the crowded streets of large cities, as found in the process of trenching, is one of its chief advantages. The main reasons which have led to the extensive use of wrought-iron piping in the subways are its great strength, its adaptability to varying conditions of the street, and the rapidity with which it can be laid. The Edison system consists of wrought-iron pipe, in which are placed the copper conductors or rods. These conductors are wound with rope, and the pipe is filled with an insulating compound of Trinidad asphaltum, rosin, paraffin, and linseed oil. These iron pipes are laid directly in the earth. There are about fifty miles of this pipe now laid in New York City.

The subways are in many cases on both sides of a street, and, as a rule, the telegraph and telephone wires are assigned to ducts on one side of the street, and the electric light wires to ducts on the opposite side; but in numerous instances the electric light wires are operated in distributing ducts on the same side of the street as the telegraph and telephone wires, and without detriment to the latter.

Access is had to the conduits of the subways by means of man-holes, placed at an average distance of about $\frac{1}{25}$th of a mile apart. The man-holes are, with a few exceptions, built of brick laid up in concrete cement, with hydraulic concrete bottom. The outside of the walls is coated with cement to prevent moisture and gas from penetrating. Access to the man-holes from the street is had through the cast-iron head which is set on the brickwork, and which is provided with double covers. The upper or street cover weighs about 350lb.; the lower cover is provided with a rubber gasket to prevent ingress of street water into the man-holes. This cover is funnel-shaped, in order that any water which may enter through the upper cover may be drained away from the gasket. The lower cover is screwed down upon the gasket by a gun-metal bolt and cross-bar. The upper cover is loose upon its bearings. The ducts enter the man-holes at a point easily accessible to the workmen while standing on the bottom of the man-hole. The average width of the man-holes is about 5ft., and varies from 5ft. to 10ft. in depth.

The foregoing mentioned conduits may be considered as belonging to the regular subway system of New York city. There are, however, several other conduits in operation, namely, the Brooks, the Western Union, and about five miles of telephone cable laid in wooden boxes filled with sand. The Brooks system has been repeatedly described. The Western Union subway consists of an iron pipe about 6in. in diameter, into which wires have been drawn.

All the electrical subways of New York, with the exception of the Edison system, are on the drawing-in-and-out systems. As many as six electric light cables, No. 6 B.W.G. conductors, have been repeatedly drawn at once into a 3in. duct. It is not deemed advisable to draw cables into or out of ducts over cables already laid, but in case of necessity it has been done without injury to the cables. As the weight of a No. 6 B.W.G. lead-covered cable is for 300ft.—say, 250lb.—an idea may be obtained of the force required to draw in six such cables. Cables weighing in the aggregate 5,510lb. have been drawn at one time into one duct.

It is a comparatively easy problem to arrange an electrical subway for trunk line circuits. The difficulty arises when the question of distribution of the current from the main conduits is to be considered, as when, in the case of the telegraph and telephone service, it is desired to furnish city customers with circuits; and in the case of electric light service, when it is required to make house-to-house or street lamp connections. In the case of telegraph and telephone distribution, subsidiary pipes or ducts are generally led from an adjacent man-hole to the front or side of buildings, whence the cables are continued to the roof of the building or to the back yards, from which latter points the circuits are radiated as required. The cable of the telephone company is generally made up into fifty pairs. When this number of circuits is not required in one block or series of blocks, the cable is forked in the man-hole, one portion of the conductors being led in a smaller cable in one direction, another portion elsewhere as may be required. This method of distribution has been found convenient and satisfactory. Distribution of the electric light current is effected in several different ways in the New York subways. For street arc lamps the circuit is usually looped from the man-hole to the lamp post through a subsidiary iron pipe. For easy access to houses and to lamps in the middle of blocks, distributing ducts are laid over the trunk ducts as near the surface of the street as practicable, the average distance from the surface of the street being, perhaps, 18in.

SOCIETY OF CHEMICAL INDUSTRY.

MANCHESTER SECTION.

On the 5th inst. a discussion on the Technical Instruction Act took place. The Chairman, Mr. I. Levinstein, in opening the proceedings, read a letter from Mr. W. Mather, M.P., which explained the working of the Act

In the letter Mr. Mather said that the apprehension that the Science and Art Department would become master of the situation wherever the Act was adopted was utterly groundless. The object of the Act was to decentralise, by enabling local authorities to establish or aid schools of science and art with special branches of instruction adapted to the requirements of their respective districts, and the local control of such schools was as safely guarded under the Act against interference by the Department as municipal control was guarded against interference of the Local Government Board. The only possible control of the Department would be that of rejecting any subject in the list which did not come within the scope of the Act.

The power to give an authoritative interpretation of the scope of the Act must naturally rest with the Department, but beyond this it had no special power to dictate what subjects should be taught or to control the teaching. From every point of view the most complete control would rest with the local authorities over any schools

Digitized by Google

of technical instruction which were assisted by the local rate levied under the Act.

Mr. Levinstein, in a few remarks on the letter, said that manufacturers now seemed convinced that there was need for more extended and thorough teaching of technical subjects and the scientific principles involved. Technical schools were not, and should not be, self-supporting, because the fees would then be too high for the class of students they sought to benefit. He thought that Mr. Mather's letter would clear up the doubts of the members with respect to South Kensington's control over the Act.

In the discussion which ensued, Mr. Forbes Carpenter addressed the meeting at some length, going into the history and development of the Act. He reminded them that before the Act was passed Manchester had petitioned against its being made compulsory, and said they would notice as a feature of the Act the words, "a local authority *may*"—not *must*—"adopt the Act." He next referred to the School Board's objections to the Act, and said that, with respect to technical education, the School Board of Manchester was far behind that of Birmingham.

Dr. G. H. Bailey said that, after hearing Mr. Mather's letter, he was able to move his proposed memorial to the City Council to adopt the Act. He went on to contend that the classes of the Department did not fulfil the requirements of technical education, and said that of the 50,000 people connected with the manufacturing industries in Manchester, not 5 per cent. attended any classes bearing upon their manufactures. This state of affairs was quite different in Germany. The co-operation of the manufacturers and the City Council was needed in this matter.

Mr. H. Grimshaw said they could only speak for the chemical trades, and it was desirable to know how far the Act, which a circular of the National Education Association had described as an obscure one, was capable of being carried out. It certainly should not be done under the present examination system of South Kensington. More inspection and less examination was wanted. After referring to the inability of the greater part of the House of Commons to deal with this subject, and to the lack of professors of technological chemistry in this country, he declared strongly in favour of home rule in technical education.

Mr. Reynolds (secretary of the Manchester Technical School) said that it was proposed to ask the City Council for a ½d. rate, which would be shared by other educational bodies in the city. The Act would put technical schools on quite a new and improved basis. A committee of the City Council, assisted by the Manchester Section, would be much more fitted for carrying out the Act than such a body as the School Board.

GLASGOW SECTION.

On the 4th inst. a paper on the "Manufacture of Blasting Gelatine" was read by Mr. George MacRoberts, late manager of Messrs. Nobel's Works, Ardeer. The blasting gelatine patented by Nobel, the inventor of dynamite, in 1875, consists of a mixture of nitro-glycerine and nitro-cotton. When perfectly made it is a clear, semi-transparent substance of specific gravity 1·5 to 1·55, slightly elastic, and somewhat resembling india-rubber. It usually consisted of 92 per cent. to 93 per cent. of nitro-glycerine, and 7 per cent. to 8 per cent. of nitro-cotton. After giving, in the words of the inventor, a short account of the compound, Mr. MacRoberts described the gelatine-making machine used at Ardeer. He then pointed out that, in consequence of the stringent regulations of the Home Office Explosives Department, the buildings wherein the manufacture was done required to be well separated from each other, so that in case of an explosion the destruction might be confined to as small an area as possible. In carrying out the making of blasting gelatine, therefore, the following routine was observed:—The nitro-cotton required was first brought from the nitro-cotton drying stove, weighed off in the quantity required for each charge, and put into gutta-percha or brass-lined wooden boxes capable of holding enough of nitro-glycerine and gun-cotton together for the charge of a gelatine making machine. A number of these boxes, containing a quantity not exceeding the total allowed by the regulations, was then taken to the nitro-glycerine washing-house, and the proportion of nitro-glycerine required was weighed off and added to each box. The boxes were then conveyed to the gelatine-making house and the contents transferred to the pans of the respective gelatine machines. As each pan was charged, it was put under the stirrers, screwed up, and the machine started, and in the course of about an hour the gelatinisation was complete, and the pan ready to be cleaned out for another charge.

Of all the nitro-glycerine explosives, blasting gelatine was the strongest. It was specially suited for blasting in water. The manufacture of the article in this country was confined to one firm—Nobel's Explosives Company. Although the patent expired last year, yet the manufacture was surrounded with so many difficulties that it was very improbable the monopoly would be disturbed for a long time.

A paper on the "MacArthur-Forrest Process of Gold Extraction," by Mr. J. S. MacArthur, was also read He gave a very full detail of the process (which might be called the cyanide process), and expressed the opinion that it would take a front rank among all the processes for gold extraction.

LIVERPOOL SECTION.

The fifth meeting of the Session was held at University College, on the 5th inst., when Mr. T. S. Rigby, F.C.S., read a paper on "Sulphate of Lime in Cement, and a Direct Process of Calcination." In referring to the introduction of Chance's sulphur recovery process, the author of the paper pointed out that many were of the opinion that the residual lime mud obtained in the process contained too much sulphate of lime to be of use in the manufacture of cement. He had, however, prepared cement from this source, and the product had shown itself quite equal in quality to London cement. The tensile strength of the freshly prepared cement is somewhat low, but it stands the test of time effectually. In fact, the setting properties of cement can be restrained to an almost unlimited extent by the addition of plaster of Paris; hence the presence of the calcium sulphate in cement interferes with the testing very materially. Cements with more than 4½ per cent. of sulphate of calcium have a decided tendency to crack and break up. The author assigns 3 per cent. as a limit for the sulphate of lime that can exist in cement without prejudicial effects.

Notes.

THE SUEZ CANAL TRAFFIC.

THE following table shows the traffic through the Suez Canal during the years 1887, 1888, and 1889, and at the same time shows the leading position occupied by British shipping in the traffic :—

	1887.	1888.	1889.
Total vessels	3,137 ...	3,440 ...	3,425
British vessels.....	2,330 ...	2,625 ...	2,611
Total tonnage	5,903,024 ...	6,640,834 ...	6,783,187
British tonnage	4,516,773 ...	5,223,255 ...	5,352,886
Revenue (francs)	57,862,371 ...	64,832,273 ...	66,167,579

THE SIBERIAN RAILWAY.

THE Russian Government seems to be seriously contemplating the construction of the great Siberian railway entirely on its own account, thus carrying out its policy of having all the railways directly under State control. The committee appointed to report on the matter has concluded its work, although the scheme may yet undergo some modification. The question of funds, however, is still to be arranged, and we are afraid that this will cause more difficulty than the actual construction. The development of the trade will be gradual, and the line is not likely to pay a dividend for some time, and even if the Government pledged its credit, that does not stand sufficiently high to make it likely that the money would be forthcoming on easy terms. The line will be fully 4,300 miles long, and the preliminary estimate is about 28 millions sterling. The cost of construction per mile ought not to be very great, as the country traversed is mostly flat and well timbered, and there are few broad rivers to cross.

UNFENCED MACHINERY.

A CASE of interest to employers of labour who employ young persons with unfenced machinery has been decided by the Queen's Bench Division. The Employers' Liability Act holds the employers liable for accidents which occur through defects of the machinery, and the presiding judges have decided that the absence of fencing constituted a "defect" in a machine rendered dangerous by such absence. The plaintiff, a boy under sixteen, had his hand crushed in the cogs of a leather pressing machine which he had been employed in feeding, and a jury awarded him damages; but in an application to set aside the verdict it was argued that danger is not a defect in a machine if the machine is not defective in anything required for its object—in this case, of rolling leather. Lord Coleridge, while admitting that it was difficult to define a "defect," held that in the case under dispute such existed, for the injury was caused by the condition of the machine at the time—that is, in the manner and circumstances under which it was used. The machine could not work by itself, but required to be fed by boys, and that could not be done without danger if the machine were unfenced. Although the machine was not defective with reference to its purpose, it was so with reference to the danger arising from its use. Lord Esher concurred, saying that any other view would render the Act valueless to workmen. Leave to appeal was refused.

DETECTION OF WOOD IN PAPER.

MM. R. GODEFFROY AND M. COULON have worked out a method for estimating the amount of woody tissue in paper, based on the fact that cellulose which has been extracted with water, alcohol, and ether does not reduce a solution of gold chloride, whereas wood pulp quickly reduces such a solution on warming to metallic gold. They find that 100grms. of well-dried sawdust are capable of separating 14·285grms. of gold from its solution. In examining paper by this method they remove size by treating the material with cold and hot water, and then extract alumina by washing with an alcoholic solution of tartaric acid. The paper after this treatment is tried and extracted with alcohol and ether, and then treated with the gold solution.

THE FOREIGN OUTPUT OF COAL.

ONE thing which must be kept in mind when considering the price of coal in this country, is the effect which high prices will have on the output of coal in foreign countries and the Colonies. In Japan, for instance, the output has increased to a very large extent, and considerable quantities are now exported to several parts of China and the East. Then, again, in New Zealand, California, and British Columbia the coal trade has received large development, and as the resources in these countries are large, a much greater increase is likely to take place. Even in France the production has increased to a considerable extent, a good part of which has been used in supplanting that supplied from England. The Mines Department of the French Ministry of Public Works has published particulars of the production of coal for last year, showing that the total output was 24,588,880 tons, being an increase of nearly 2,000,000 tons over 1888, and 3,000,000 tons over 1887. The increase would have been still larger if it had not been for the strikes which occurred during the past year in the basins of the Pas-de-Calais and the Nord. The southern companies especially have made great efforts to increase their sphere of action, and supply the Mediterranean ports, which have hitherto been provided chiefly with English coal. These facts should be carefully borne in mind when the question of a strike in the coal trade is seriously contemplated.

THE LAW OF LIMITED LIABILITY COMPANIES.

WE have often pointed out the necessity for an improvement in the law relating to Limited Liability Companies, and we are glad to find that at least one effort is to be put forth in that direction during the present Session of Parliament in the way of bringing home to the directors of a company and others the responsibility for the statements in their prospectuses. A Bill has been introduced by Mr. Warmington, Q.C., which provides that every prospectus of a company, and every notice inviting persons to subscribe for shares or debentures is to be deemed to contain a "warranty" of certain things by every person who is a director at the time of the issue of the document, or who is named in it as a director, or as having agreed to become one, and also by every other person who has authorised its issue. The warranty is to be that every statement of fact in the document is true, and also that every statement of or extract from any report of any engineer, valuer, accountant, or other expert contained in it is a true and fair statement of or extract from the report, and that the report was made by the person whose name it bears. Moreover, it is to be regarded as warranted that the directors, &c., have reasonable ground for believing, and do believe, that the report was made in good faith, and that the person making it was competent to report on the subject. The right of action of successful applicants for shares against the directors, &c., is to be the same as if the warranty were included in a contract for sale. This should make directors or organisers very careful of the statements which they make in their prospectuses.

ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.

ENGINEERING.

Turn-Tables and Cranes.—*W. Williams, St. Ives, Cornwall.*—To reduce the friction in turning turn-tables and cranes and to simplify their construction the inventor supports them upon ball bearings. The balls are arranged in a horizontal and circular groove situated under the table. A corresponding groove is attached to the underside of the table, and the balls revolve between the two when the table is turned. The grooves are situated near to the edge of the table. Claims: (1) The use of turn-tables with circular grooves to turn round on ball bearings; (2) the construction of turn-tables as herein described with ball bearings in circular grooves on which the tables turn round and the balls move freely in endless succession; (3) the use and construction of turn-tables (for any purpose) with ball bearings placed in grooves to run freely round in endless succession.—No. 4847. March 20th, 1889. 6*d*.

Rotary Engines.—*D. Williamson, Brooklyn, U.S.A.*—The engine is constructed to be worked by a fluid such as water under pressure, but may be used for pumping and other purposes. It consists of an annular chamber, in which work feathering vanes. The continuity of the annular chamber is broken by an abutment, which receives the back pressure of the working fluid, whilst the vanes receive the forward pressure and cause the shaft to revolve. The abutment is formed with a slot, which is of sufficient width to allow the passage of the vanes when they are feathered or turned round at right angles to the position they assume at the time of receiving the working pressure. In the illustrations, Fig. 1 represents a side elevation of the motor,

FIG. 1.

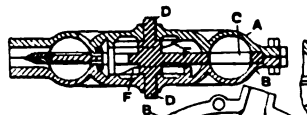

FIG. 3.

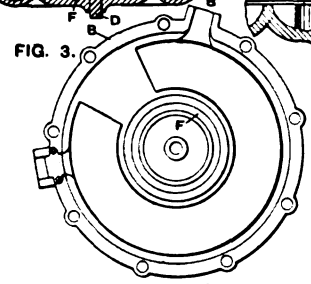

FIG. 4.

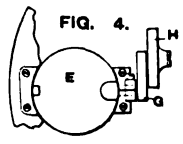

FIG. 5.

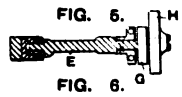

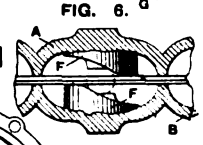

FIG. 6.

Industries

with one half of its casing removed; Fig. 2 is a central section, taken in the plane of the shaft; Fig. 3 shows one of the casing halves, Figs. 4 and 5 details of a vane, and Fig. 6 a sectional view showing the cam for feathering the vane. Between the two halves A B of the casing is a thin plate C, which is fixed to the shaft D and carries the vanes E. The vanes are supported in the plate C by pivots, and to these pivots are connected the cranks G (Figs. 4 and 5), which carry the friction wheels H. In the central part of the casing is a chamber containing the cam F, which, by guiding the friction wheels H, feathers the vanes as they pass the slot in the abutment. Seven claims are made for the engine described and certain modifications.—No. 18956. November 26th, 1889. 8*d*.

Lock-Nut.—*J. W. Smallman, Nuneaton, Warwick.*—The nut has a base lying in a plane which cuts the axis of the bolt otherwise than at right angles—that is, a nut a portion of whose base only has contact with its seat when screwed home. The effect of screwing such a nut down is to gradually bend the bolt to one side, and so lock the parts in position. The tendency of the nut to unscrew is prevented, for to do so it would have to straighten or bend the end of the bolt in an opposite direction. Claims: (1) The improved lock-nut formed or operating as described; (2) a lock-nut in which the locking effect is produced by reason of the nut, when screwed home, being unable to rotate without varying the extent to which the bolt has been previously bent, as described.—No. 2633. February 14th, 1889. 6*d*.

Duplex Pumps.—*C. E. Owens, London.*—In duplex pumps worked by steam as hitherto constructed, the cylinders of the two pumps have both been supplied with high pressure steam. In some cases these duplex pumps have been compounded, that is to say each pump has had a high and low pressure cylinder. By this last arrangement a waste of power is avoided which takes place in the first. To prevent the waste of power as in the last arrangement and to simplify the parts the inventor works one pump with a high pressure cylinder and the other with a low, passing the steam from the high to the low. The cylinders are placed side by side and operate upon the pumps in precisely the same way as the two high pressure cylinders, and the piston rod of each cylinder actuates the slide valve of the other cylinder in the manner usual in duplex pumps. In order to start the pump, steam is admitted to the high pressure cylinder at full pressure and simultaneously to the low pressure cylinder at a reduced pressure, the reduced pressure being obtained by means of an ordinary reducing valve. Claims: (1) A duplex compound fluid pressure pump constructed substantially as hereinbefore described, with a high pressure cylinder and a low pressure cylinder, these two cylinders being placed side by side and operating the pumps in the same way as two high pressure cylinders hitherto used side by side in duplex fluid pressure pumps, and the piston rod of each cylinder actuating the valve of the other cylinder in the manner which is usual in duplex pumps; (2) the duplex compound fluid pressure pump constructed and working as described; and (3) referring to the pump as illustrated in the specification of patent.—No. 4112. March 8th, 1889. 8*d*.

Boiler Furnaces.—*P. McGregor, Jun., Birkenhead.*—Means are here described by which the circulation of water about or near the furnaces of steam generators may be more vigorous and effective. In the interior of the furnace are hollow rings or portions of rings having preferably one flat side, the other being semi-cylindrical. The flat side is arranged to lie against and be connected to the inside of the furnace. In the flat side of the rings and in the furnace at corresponding points are formed apertures, one or more being at the bottom and one or more at the top. The rings are secured to the furnaces at parts where the apertures are made, either by rivets surrounding the apertures or by nipples screwed through the ring and furnace plates. These apertures form the communication between the boiler and the semi-circular rings, and the circulation of the water is caused by the water within the ring becoming heated, rising to the top, and escaping by the top apertures. As the rings project into the furnace they become consequently more heated than the sides of the furnace, and circulation of water is very rapid. Claims: (1) The combination with a furnace of a steam generator of a hollow ring or rings placed within or outside the furnace and arranged with one of its or their surfaces bearing upon the same; (2) a ring for furnaces of steam generators of semicircular or analogous form in cross section, the flat surface being, on the outside, adapted to bear upon the inner surface as described; (3) the combination with a circular furnace of a steam generator of a ring or rings placed within or outside the furnace, as described, and connected thereto and having apertures therein, by which the water is free to pass in at or near the lower part thereof and leave at or near the top as and for the purposes described; and claims (4) and (5) referring particularly to the furnaces illustrated by the drawings in the specification.—No. 4990. March 22nd, 1889. 8*d*.

Steam Traps.—*W. Watson, Bradford.*—The water is collected in a small closed tank carried by one arm of a lever, the opposite arm of the lever being weighted. The fulcrum of the lever is the plug of a cock, and the arm of the lever supporting the vessel is hollow. The vessel communicates with the plug of the cock by two channels in its supporting arm. One of these channels is in communication through the cock to the pipe from which the water is to be run off, and the other through the cock to the outlet for the discharge of the water from the vessel. The counterweight upon the lever is sufficient to balance the collecting vessel and a certain quantity of water, so that when the vessel is empty it is held up by the counter-weight and the discharging channel is closed. After a quantity of water has collected, however, the weight causes the vessel to drop, and the discharge valve becomes opened and the water discharged. Claims: (1) The construction of a steam trap in such a manner that the letting off of condensed water is controlled by a tap which, when sufficient water has collected, is opened by the weight of the water, and is again closed by the action of a counterbalance weight when the collected water has been discharged; (2) the construction of steam traps as described.—No. 5500. March 30th, 1889. 8*d*.

Spinning and other Machinery.—*J. Boyd, Glasgow.*—The invention comprises an improved combination of mechanism for lifting and lowering the building or traversing rails of spinning, roving, twisting, and analogous machines. The mechanism is shown in the accompanying illustrations, Fig. 1 being a side elevation, Fig. 2 an end elevation, Fig. 3 a horizontal section, and Figs. 4 and 5 details. The mechanism shown in the drawings is in part carried by a casting A bolted to a transverse frame B of a spinning or other machine. The building or traversing

FIG. 1.

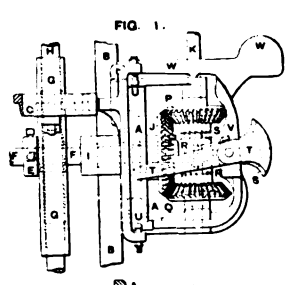

FIG. 2.

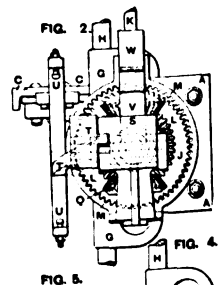

FIG. 3

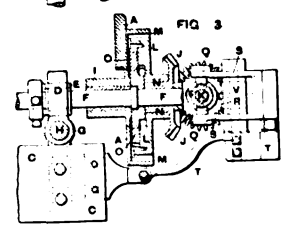

FIG. 4.

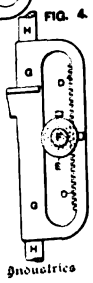

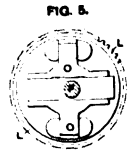

FIG. 5.

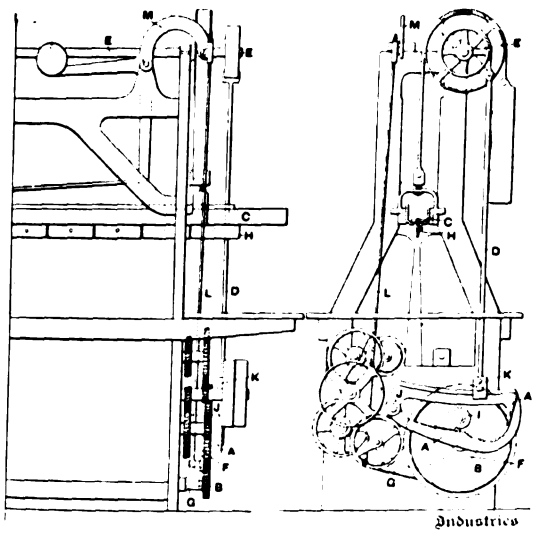
Industries

rails, of which a part C is shown, are lifted and lowered by means of vertical racks D (shown in detail Fig. 4) geared to pinions E on a longitudinal shaft F. The racks are formed on or fixed to tubular guides G sliding upon the rods H. The shaft F extends through a bearing I and supports a mitre wheel J which is in gear with two others upon the driving shaft K. The mitre wheel J is mounted loosely upon the shaft F and has a long eccentric boss N which supports the outer toothed wheel L gearing with the inner toothed annulus M. The inner toothed annulus M is stationary, and constitutes with the outer toothed wheel L

Digitized by Google

mounted upon the eccentric boss N a well-known form of differential gear, used in this case to reduce the speed of the shaft F. The outer toothed wheel L is connected, by pins working in slots, to the collar O fixed to the shaft F, which consequently receives a reverse motion to that of the mitre wheel J. To reverse the motion of the shaft F necessary for the up and down action of the rack, the two mitre wheels P and Q are alternately connected to the driving shaft by the coupling R. The coupling R is alternately locked with the mitre wheels by the forked lever S and the tappet lever T connected to each other and worked by the tappets U attached to the traversing rail C. To hasten the action of the clutch at each end of its stroke, a lever V is connected to the other two and works upon the inclined surfaces of a weighted lever W. As the tappet lever T shifts the clutch from one position to the other the lever V gradually raises the weighted lever W until it passes the extreme point, and the weight of the lever W then presses the lever V over to its extreme position, and so throws the clutch into gear. Claims: (1) The combination of parts constituting my improved mechanism for lifting and lowering the building or traversing rails of spinning, roving, twisting and analogous machines, substantially as hereinbefore described and as shown in the accompanying drawings; (2) in mechanism for working building or traversing rails of spinning, roving, twisting and analogous machines, combining differential gear to reduce speed, with a three-bevel wheel arrangement having a reversing clutch moved by adjustable tappets traversing with the rails and combined with a heavy tumbler lever, the parts being constructed, arranged, and operating substantially as hereinbefore described.—No. 4593. March 16th, 1889. 8*d*.

HACKLING MACHINES.—*A. Combe, Belfast.*—These improvements in hackling machines are applied to the appliances for raising and lowering the channel which carries the holders, and also for sliding the holders from over one tool to over another. Figs. 1 and 2 give views of a hackling machine, with the improvements attached. The novelty of the invention for raising and lowering the channel C, which carries the holders H, consists in the peculiar form of the lifting lever A. The lever A is made in the form of a loop, and is rocked upon the stud J by a runner I upon the main wheel B. To the upper side of the loop is attached a connecting rod D, which imparts a rocking motion



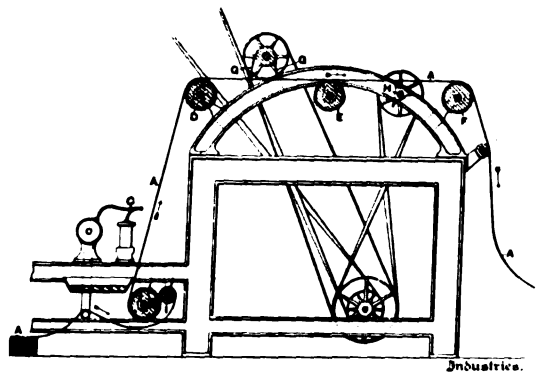


FIG. 1. FIG. 2.

to the lifting shaft E at the top of the machine. The rod D is attached to the loop by an adjustable joint K. The surface of the looped lever upon which the runner I travels is formed so that the desired differing rates of speed are given to the channel C which carries the holder H. The novelty in sliding the holders H from over one tool to over another consists in using a cam F, fixed to the main wheel B, and actuating a lever G connected by the rod L to the weighted lever M. The cam F raises the ordinary weighted lever M, while the holders H are stationary in the channel C, and liberates it when the channel C is at rest at its highest position in order to enable the weighted lever M to slide the holders H from over one tool to over another. Claims: (1) The looped lever A, and adjustable clip attachment K, and a runner such as I all in combination, for giving the lifting motion in hackling machines, and as herein described, and substantially as illustrated by drawings; (2) the sliding cam F on the opposite side of the wheel B to runner K and lever G in combination as and for the purposes herein set forth, and substantially as illustrated by drawings.—No. 4834. March 28th, 1889. 6*d*.

LOOMS.—*H. Hartley, Nelson, Lancashire.*—This invention relates to the construction of picking bowls and studs for looms. The picking stud is constructed of cast iron, and in it is formed a hole for the admission of the picking shaft. The stud is slid upon the picking shaft and secured at any point by a set screw. The part of stud on which the picking bowl or cone works is conical to fit a conically shaped hole in the bowl or cone. Claim: A picking bowl or cone and stud, constructed as described.—No. 5569. April 2nd, 1889.

CHUCKS FOR LATHES.—*J. Barlow, Coventry.*—The body of the chuck is disc-shaped, similar to the ordinary face plate of a lathe. Upon the face of this plate, and upon opposite sides of the centre, are two sliding jaws, movable in the same straight line. One jaw has a V-shaped recessed gripping face, and the other sharp edges with which to hold the work. The work when held by the chuck rests upon the two faces of the V-shaped jaw, and is held firmly against them by the other jaw. The V-shaped jaw may be attached to the plate by two bolts working in parallel slots, diametrically opposite to the slot in which the other jaw slides. By this connection of the block it may be adjusted as required to or from the centre of the lathe, and its faces inclined equally or unequally to the direction of its sliding motion. If the faces of the V-shaped jaw should be unequally inclined to the direction of the motion of the jaws, circular work will be held in the chuck eccentrically to the lathe centre. The V-shaped chuck when adjusted for work may be fixed, and similar work removed or placed in the chuck by moving the other jaw. One claim is made for the chuck described.—No. 5662. April 2nd, 1889. 6*d*.

APPARATUS FOR TREATING CLOTH.—*A. & R. Brearley, Batley.*—By this improved machine the cloth is damped and passed in a stretched state to be operated upon by a winged beater, to raise the nap or pile. It next passes by an ordinary revolving beater operating upon its underside, and proceeding forward is passed to the tentering machine. By these means the pile is raised and kept erect until it arrives at the tentering machine. In the illustration, which is a sectional side elevation of the machine, A is

the cloth being treated. The cloth is first taken over the break roller B covered with cards, resistance to the roller's rotary motion being caused by a friction strap and weight, not shown. The cloth is next damped or dewed by means of a series of tubes or nozzles C as it passes upwards over the guide rollers D, E, and F. In travelling over the guide rollers it is beaten by the flexible winged beaters G to raise the pile, and further along it is beaten again by the ordinary beater H. In the tentering machine the front rollers are dispensed with and in place a round-faced wheel is employed near each set of hooks to take off the drag of the piece from the hooks and to keep the pile from becoming flattened. Claims: (1) The combination of break roller B, guide roller I, dewing or damping apparatus C, guide rollers D, E, F, and winged beaters G and H, operated as and for the purposes substantially as shown and described; (2) the use and employment of the winged beater G operating upon the face of the cloth substantially as shown and described; (3) the general arrangement and construction of apparatus substantially as shown and described; (4) in tentering machines, the use and employment of a round-faced wheel or disc at or near each set of hooks for the purposes described.—No. 3764. March 4th, 1889. 8*d*.

FLY WHEELS.—*D. Halpin & I. A. Timmis, London.*—This description of fly wheel is constructed so that it may be readily and economically made, and yet shall have sufficient strength to resist centrifugal breaking strains when driven at a high velocity. The boss and arms of the wheel are made in any convenient or known manner. On the arms is fitted a rim in the shape of a channel or groove. In this groove is wound a sufficient number of layers of metal wire to give the weight required to the fly wheel. Existing fly wheels may be strengthened by attaching discs or rings to their rims to form troughs and filling these with wire coils. Claims: (1) The making or forming a groove or grooves in the periphery of wheels which are used as fly wheels or otherwise, for the purpose of putting a coil or coils of wire or tap in the manner and for the purpose described; (2) the coiling or winding of wire or tape on the periphery of fly or other wheels, as and for the purposes described.—No. 5755. April 4th, 1889. 6*d*.

HIGH-SPEED ENGINES.—*A. Sneath, London.*—The engines referred to in this specification are of the duplex type, with cylinders arranged in the same axial line. The piston rods are connected to a link whose slot is straight and placed vertically and at right angles to the piston rods. In this slot the crank or crank pin of the engine works upwards and downwards as the pistons make their strokes. The two cylinders may be operated by high pressure steam, or one with high and the other low. Two or more sets of cylinders may also be connected to the same crank shaft. Claims: A high-speed engine, the cylinders of which are placed in pairs, each pair being adapted to operate upon a single crank without the employment of connecting rods as described; (2) the manufacture and use of the improved engine hereinbefore described.—No. 5859. April 5th, 1889.

DIES FOR ROLLED FORGINGS.—*H. H. Lake, London. (The Gould Rolling Machine Co., Leominster, U.S.A.)*—These dies are specially applicable for use with rolled forging machines having a vertical, rotary, or reciprocating movement. The parts of the machine to which the dies are attached have longitudinally concave and convex surfaces which are arcs of a circle described from the centre of rotation. The concave surface of the one part is opposite to the convex surface of the other. Upon these surfaces dies of novel design are placed, having their longitudinal sections to correspond with the surface to which they are attached; thus, one is concave and the other convex. The dies gradually taper from the ends they commence work to the rear ends, so that the rear ends are of the finished form of the work. In dies for rolling globular forms the working surfaces of the dies are formed at one end with a small arc of a circle corresponding to the surface of the globe, and gradually increasing towards the other end in its cross section to a semi-circular shape. Both dies are similar in cross section, and as they revolve in contrary directions a similar cross section of one corresponds to a similar cross section of the other, so that when the full parts of the dies pass each other their combined surfaces form a complete circle. The edges of the dies are bevelled and are punctured or indented, to prevent the dies slipping upon the work instead of rolling it. Claims: (1) A die for making rolled forgings having a concave working face comprising a longitudinally arranged groove semi-circular in cross section and formed between diverging cutting and spreading bosses having outwardly inclined indented faces; (2) companion dies for making rolled forgings having their working surfaces respectively concave and convex in longitudinal section and provided with cutting bosses having indentations in their spreading faces; (3) a die for making rolled forgings having a working face convex in longitudinal section, said face comprising a cross sectional semi-circular groove formed between diverging cutting bosses having outwardly inclined spreading surfaces provided with indentations; (4) dies for making rolled forgings having indentations in the spreading faces as described.—No. 20966. December 31st, 1889. 6*d*.

SELF-ACTING MULES.—*W. Bryden & H. Stansfield, Leeds.*—These improvements in self-acting mules are for the purpose of simplifying and more readily reversing the motion of the spindles for producing different twists of the warp and weft threads. The spindles are driven by cords or bands from one cylinder or "tin-roller," extending the full length of the machine. In the present form of machines, to change the twist of the thread from a right to left hand twist, the whole of the cords or bands driving the spindles had to be changed from cross bands to straight bands, or *vice versâ*. In the present improvements this change is made by reversing the motion of the "tin roller." This is effected by gearing the roller by tooth wheels to one end of a counter shaft. To the other end of the shaft is attached a second toothed wheel, which gears by an intermediate wheel with a toothed wheel upon the driving shaft. When the machine is required to be reversed the intermediate wheel is removed, and the wheel upon the driving shaft moved to gear directly with the wheel upon the counter shaft. Claim: The means employed for reversing the action of the cylinder or "tin-roller," and consequently the motion of the spindles, without the necessity of removing or altering the position of the driving cords or bands, as and for the purposes described.—No. 346. January 8th, 1890. 6*d*.

CALCINING FURNACES.—*E. B. Parnell, London.*—This invention relates to calcining furnaces, and refers principally to that class of muffle calcining furnaces which are horizontal. According to this invention, these furnaces are caused to rotate, whilst in use, on rollers or the like, to avoid the injurious effects of unequal expansion and contraction. In the accompanying illustrations Fig. 1 is an elevation partly in section; Fig. 2 a transverse section on the line X X, Fig. 1; Fig. 3 a transverse section on the line Y Y, Fig. 1; and Fig. 4 a detail. A is the shell or body of the furnace, built up of cast-iron plates and mounted upon the bearing rollers F, which are revolved by the mechanism

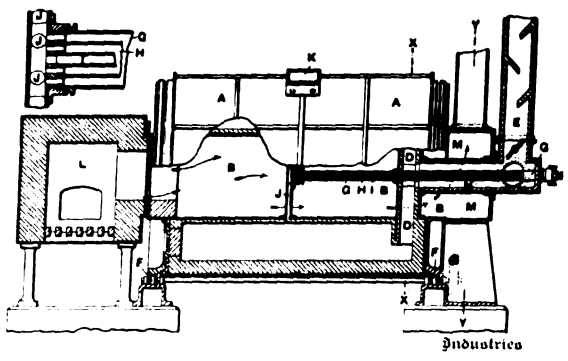

FIG. 1.

shown in Fig. 3. A tube B occupies the central part of the shell A, and the remaining part is divided by plates into six chambers C. A discharge pipe E communicates with the chambers C by the branch pipes D, and concentric pipes G, H, and I, by the branch pipes F, to convey respectively air, gas, and steam to the chambers. The method of working the apparatus is as follows:—The calcining chambers C are charged with material through doors K, and the whole furnace revolved slowly upon the rolls. A fire is raised in L, and the products of combustion conducted through the central tube B into the uptake M. Steam, air, and gas are admitted as required to the calcining

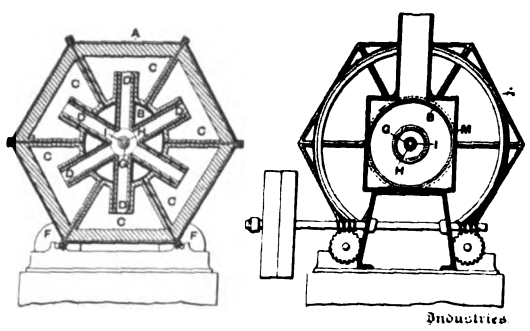

FIG. 2. FIG. 3.

chambers, and the fumes given off by the material are conducted away by the pipes D, as already mentioned. Claims: (1) In a calcining furnace a rotating body or shell, such as A, the interior of which is divided into a number of longitudinal chambers substantially as herein described and illustrated in the accompanying drawings; (2) in a calcining furnace the arrangement of the pipes H, G, I one within the other, so that the innermost pipe is protected against the surrounding high temperature, so as to ensure that the steam which is passed through it to the calcining chambers will be delivered in a saturated condition; (3) in a calcining furnace a horizontal shell or body, such as A, mounted on frictional driving rollers, to which rotary motion is imparted by worm or equivalent gearing substantially as herein described and illustrated in the accompanying drawings; (4) in a calcining furnace the combination with a central stationary outlet pipe, such as N, of a number of rotating branches, such as D, connecting it with the calcining chambers; (5) the general combination and arrangement of parts constituting the complete calcining furnace substantially as herein described and illustrated in the accompanying drawings.—No. 4354. March 12th, 1889. 8*d*.

Digitized by Google

ANTI-FRICTION RINGS.—*A. M. Clarke, London.* (*J. J. Ladd, Callao, Peru, South America.*)—The anti-friction ring is designed to be placed upon axles and shafts between the collars or boxes of wheels and journal boxes. It consists of a split ring enclosed by a collar, which is divided for convenience in applying the ring to a shaft or axle, and a lubricating device formed on or attached to the collar for maintaining a constant lubrication. The split ring is made in halves, whose ends naturally interlock with each other. In the one part is formed a key seat which fits a key fitted to the shaft upon which the ring is placed. The split ring is made of hardened steel. A collar of iron is fitted to the ring, and is provided with a removable section of sufficient width to permit the placing of the collar upon the ring. The collar is formed with a block on its edge, in which are made oil chambers which communicate with each other and with a passage leading to the interior of the collar, the oil, which is gradually supplied through the said passage to the interior of the collar, maintaining a perfect lubrication of the collar without depending upon the oil supplied to the journal box. Two claims are made for the anti-friction collar described.—No. 19797. December 9th, 1889. 6*d.*

ELECTRICITY.

GENERATION OF ELECTRICITY ON RAILWAY TRAINS.—*I. A. Timmis, London.*—The electricity is generated by a dynamo, for the purpose of lighting lamps, working brakes, charging accumulators, or for other similar purposes. The dynamo is fixed in any convenient vehicle, for instance a guard's van, and driven by a steam engine, which may either take steam from the locomotive or from a special boiler. If a special boiler is used, it is preferably placed with the dynamo and engine in the same vehicle. When a quantity of water is required to cool parts of the engine, the water used for the purpose may be circulated through the train to warm the compartments. The heat in the fire-box of the special boiler may be used to heat a system of pipes or tanks containing chemicals, such for instance as the Arctos system or the Harden Star system, for the purpose of cooling the compartments of the train. Claim: The combined arrangement hereinbefore described for driving an engine, and also providing means for heating or cooling railway vehicles, as and for the purposes described.—No. 5615. April 2nd, 1889. 6*d.*

REGULATOR FOR ELECTRIC CURRENTS.—*W. R. Michl, Wettr-on-the-Ruhr, Germany.*—The regulator is self-acting, and is operated by weights, which are controlled by a system of electric magnets and solenoids. Fig. 1 is a front elevation, and Fig. 2 a side elevation of the appliance. A are contact plates arranged in an arc and connected to resistances. B is a spring contact arm for putting the different resistances in circuit. The arm B is attached to a wheel C^1, which may be revolved in either direction by the

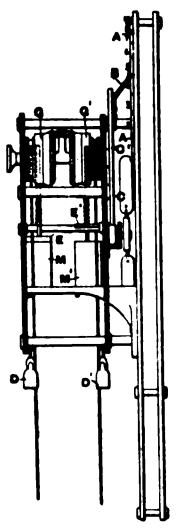

FIG. 2.

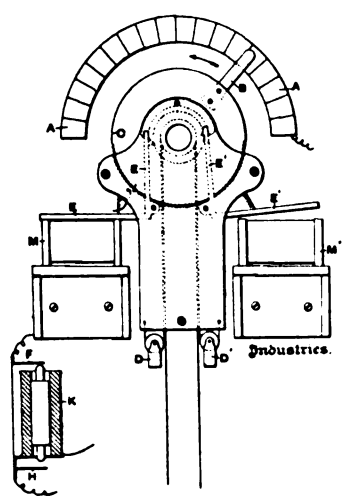

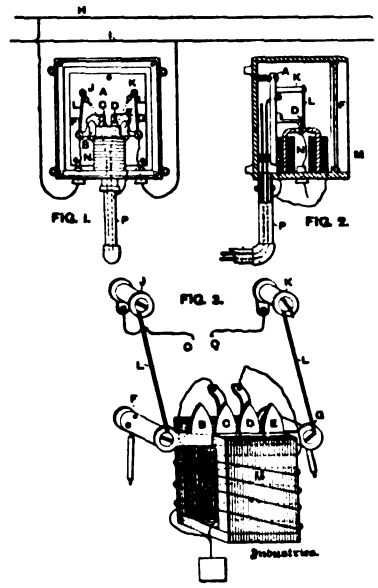

FIG. 1.

weights D D^1. The weights are suspended by chains passing round the drums G G^1. In the drums G G^1 fall the pawls E E^1 to prevent the weights turning the wheel C^1. The wheel C^1 is geared to a fly-wheel C to make its motion slow. The pawls E E^1 are situated above electromagnets M M^1, which are vitalised as required by a controlling solenoid K. The pawls E E^1 are held away from the magnets M M^1 by springs, but should the current exceed the normal the core of the solenoid K is raised and makes contact with F, and puts the electromagnet M in circuit. The arm E is then drawn down and the wheel G permitted to revolve, turning the wheel C^1, and so shifting the contact arm B to put in more resistance. When the current has become normal the arm E is released, and the contact arm remains stationary. If the current falls below the normal the core makes contact with the plate H and puts the magnet M^1 in circuit when the arm B is moved in a contrary direction. Claims: An improved regulator for electric currents arranged substantially as described and shown in the drawings.—No. 18,979. November 26th, 1889. 6*d.*

SAFETY DEVICES FOR ELECTRIC CIRCUITS.—*H. H. Lake, London (E. Thomson, Lynn, U.S.A.)*—The invention relates to lightning arresters for use in connection with lines which carry currents of considerable potential. In the accompanying illustrations Fig. 1 shows a front view of the lightning arrester. Fig. 2 a side view in section, and Fig. 3 the essential electrical elements of the invention separated for clearness. A slab of non-conductive material A is fixed in a casing of metal, and supports the lightning arrester plates B C D E. The plates B E are supported by the standards F G_1 which are electrically connected to the main leads H I, whose difference of potential is great at those parts. The standards F G are further connected with terminals J K by fuses F. From the terminals J K connection is made by insulated wires passing downward through the pipe P to any suitable device, such as a motor or induction coil. The plates C D are connected to earth by wires which form the coils of the magnets M N. On the occurrence of a lightning discharge which induces or produces an instantaneous flow of high potential current in either one or both of the mains H I, such flow or discharge finds its way to earth by springing across the space between the plates B C or D E. To prevent a circuit forming between H and I by an arc across the arrester plates, the magnets M N develop magnetism in the poles between which the arrester plates are placed to rupture or blow out by magnetic action any electric arc so formed. Should a short circuit occur in the lines O Q leading from J K to the induction coil the fuses L become melted and the current for the time discharged to earth. Claims: (1) The double pole lightning arrester hereinbefore described having lightning arrester points connected to both poles of the circuit,

and mounted together as a single structure, in combination with an arc rupturing magnet; (2) the combination with the double pole lightning arrester connected to the two mains or wires of an electromagnet whose magnetic poles embrace or act upon the spaces between both sets of arrester plates or poles, and a coil or coils for said magnet in a circuit from one main to the other through the arrester; (3) the combination with the branch wires of a lightning arrester, and fuses between the local translating device and said branch wires; and (4) and (5) a modification.—No. 6063. April 9th, 1889. 8*d.*

ELECTRIC SIGNALLING LAMPS.—*J. P. Rees, London.*—A portable electric lamp for signalling by flashes is here described. Fig. 1 is a side elevation partly in section, and Fig. 2 a front elevation of the lamp. The battery is enclosed in the case A upon whose lid B is mounted the lamp C and its fittings. The leading-in wires of the lamp are connected to the poles of the battery, one by the metal strip D, and the other by the metal strip E, the contact piece F, and the spring G, which is connected to the pole. The lamp C is enclosed in a case H provided with lenses I, and separated by a diaphragm into two compartments. In the diaphragm is a small aperture K closed at will by a system of levers M, N, O, and L. When it is desired to transmit a message the spring G is depressed until it bears upon the contact-piece F and is held in this position to complete the circuit through the lamp C during the working. The disc or shutter over the aperture K is then operated by pressing the lever L so as to open and close it in such a manner as to produce the desired signals. Claims: (1) A portable electrical apparatus for signalling by means of flashes of light; (2) the combination with an electric battery and an electric lamp connected therewith of a device for closing and interrupting the circuit, and a casing enclosing the said lamp and provided with one or more lenses; (3) in an electric signalling apparatus such as hereinbefore described a tube provided with

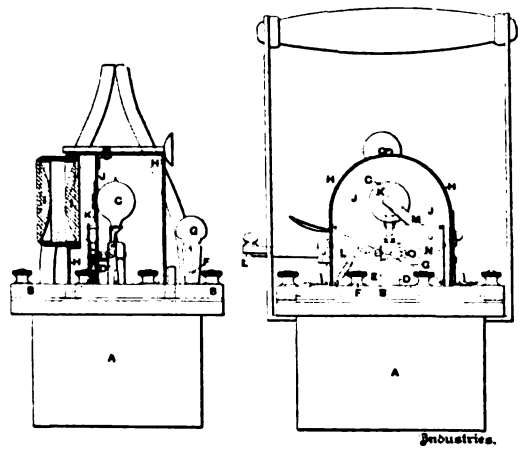

FIG. 1. FIG. 2.

one or more lenses and so fitted in a casing enclosing the lamp that it can be adjusted towards and away from the said lamp; (4) in an electrical signalling apparatus such as hereinbefore described, the employment between the lamp and the lens of a partition or diaphragm provided with a suitable aperture, and a disc or shutter provided with means for operating it to open and close the said aperture; (5) the improved apparatus constructed as described.—No. 1038. January 18th, 1889. 8*d.*

CHEMISTRY.

WATER GAS.—*S. Fox & E. Blass, Leeds.*—This apparatus is designed to generate the gas directly from water without the use of a boiler. This is effected by heating up a regenerator by gases produced during the time of blowing up the fuel in the generator. Water is then admitted under pressure into the heated regenerator, and is converted into steam. This passes through the incandescent fuel and makes the water gas. The regenerator is formed of a metal case lined with refractory material, and partially divided in two or more compartments by walls of the same material. In one of these compartments is constructed the furnace, and in the other are placed bricks or other pieces of refractory material crossed to form passages for the products of combustion proceeding from the furnaces. These bricks and the walls become heated, and the spray of water is directed upon them to form steam at the proper time as already described. The passage of the steam in the course of being converted into gas passes through the regenerator in a contrary direction to the products of combustion. Claim: In apparatus for and in the manufacture of water gas, the producing without the use of a steam boiler of steam necessary for the manufacture of such gas as described.—No. 6131. April 10th, 1889. 6*d.*

POTASSIC AND SODIC HYDRATES.—*G. A. H. Gabet, Paris.*—The above hydrates are manufactured according to this invention by the following method:—A solution of acid phosphate of lime is placed in an enamelled iron boiler, 15 per cent. of acid phosphate being a suitable strength. This solution is brought to and maintained at nearly the boiling point, and an equivalent quantity of either sulphate of potash or sulphate of soda added. Soluble phosphate of potash or phosphate of soda and insoluble sulphate of lime are thus formed. The sulphate of lime is separated by filtration. The phosphoric acid is precipitated by milk of lime and then separated. The solution of potash or soda left is concentrated to any desired degree in an iron vessel. With a very slight increase of cost precipitated phosphate free from iron and alumina and caustic soda of great purity may be obtained. For this purpose it is necessary to divide the precipitation of the phosphoric acid into two parts. First lime is added to the solution of acid phosphate of soda until a neutral or slight alkaline reaction takes place; half the phosphoric acid is precipitated in the form of phosphate of lime and di-sodic phosphate remains in solution. The precipitate of phosphate of lime is separated. In cooling the di-sodic phosphate remaining in solution crystallises, and it is separated from the water of crystallisation, and after being dissolved in warm water the phosphoric acid it contains is precipitated by the addition of the necessary quantity of lime. This second precipitate of phosphate of lime is free from iron and alumina, and the soda remaining in solution is of great purity. This process of manufacture of soda and of potash has the advantage of permitting of the employment of the double sulphates of potash, soda, and magnesia. By treating these salts with an equivalent solution of acid phosphate of lime, on one hand acid phosphate of magnesia and acid phosphates of potash and of soda—all of them soluble—are obtained, and on the other hand sulphate of lime, which precipitates and can be separated, is obtained. Claim: The manufacture of caustic potassic and sodic alkalies by the aid of phosphate of lime and the sulphates or bisulphates of potash and of soda, such process enabling phosphate of magnesia to be obtained as a bye-product when double salts which contain magnesia as one of the bases are employed.—No. 5341. March 28th, 1889. 6*d.*

WASTE SULPHURIC ACID PICKLE.—*S. Daw, Llanelly, Carmarthen.*—This invention relates to the treatment of sulphuric acid pickle to produce useful products. The liquor treated is derived from works in which tin, terne, and black plate are manufactured, it being necessary at certain stages to immerse the iron or steel plates in dilute sulphuric acid. The spent or residual liquor from this process is mixed with any suitable material containing available oxide of magnesium. The available oxide of magnesium is added in the proportion of forty pounds weight to thirty-two pounds weight of sulphur found in combination with the constituents of the waste pickle. The addition of the material containing oxide of magnesium causes by chemical action the production of oxide of iron and sulphate of magnesia. Claim: The method of treating the material usually known as spent sulphuric acid pickle with or without preliminary treatment consisting in adding thereto material containing available oxide of magnesium so that sulphate of magnesia and oxide of iron are produced.—No. 4701. March 18th, 1889. 4*d.*

MISCELLANEOUS.

INDICATOR FOR RAILWAYS.—*C. C. Hearsey, Chiswick.*—The use of this invention is to enable passengers in railway vehicles to ascertain during a journey the names of stations as the train passes through them. In each compartment there are arranged a series of plates or discs attached to an endless band passing over rollers. One of these plates is exposed at a time to the passengers in the compartment. On these plates are marked the stations in the order they are situated upon the railway track. At the stations are fixed parallel with the metal track, and by its side, a plate of metal having an edge which slopes upward from either direction. A sliding rod is affixed perpendicularly to the side of each carriage connected at its top to the spindles of the rollers over which passes the endless band carrying the station indicating plates. By thrusting this rod upwards vertically the rollers in each compartment of the vehicle are turned sufficiently to indicate a fresh station. The rod is thrust upwards by its lower end travelling up and over the edge of the plate of metal fixed by the side of the rail at each station. Thus, as the train passes through a station its name is indicated. Claim: The automatic system comprising the double incline plate, and the gear and mechanism for the purpose of turning the endless band containing the names of the station and the combination in the manner described.—No. 1984. February 4th, 1889. 8*d.*

Copies of the British specifications may be obtained on application to H. READER LACK, Esq., *Comptroller-General, Patent Office, Southampton Buildings, London, W.C. The published price must be remitted, together with a sum sufficient to cover postage, which may be reckoned at ½d. for every* 10*d. or fraction of* 10*d. Remittances exceeding one shilling must be made by Post Office Order.*

MESSRS. ARBEY'S TOOLS AT THE LATE PARIS EXHIBITION.

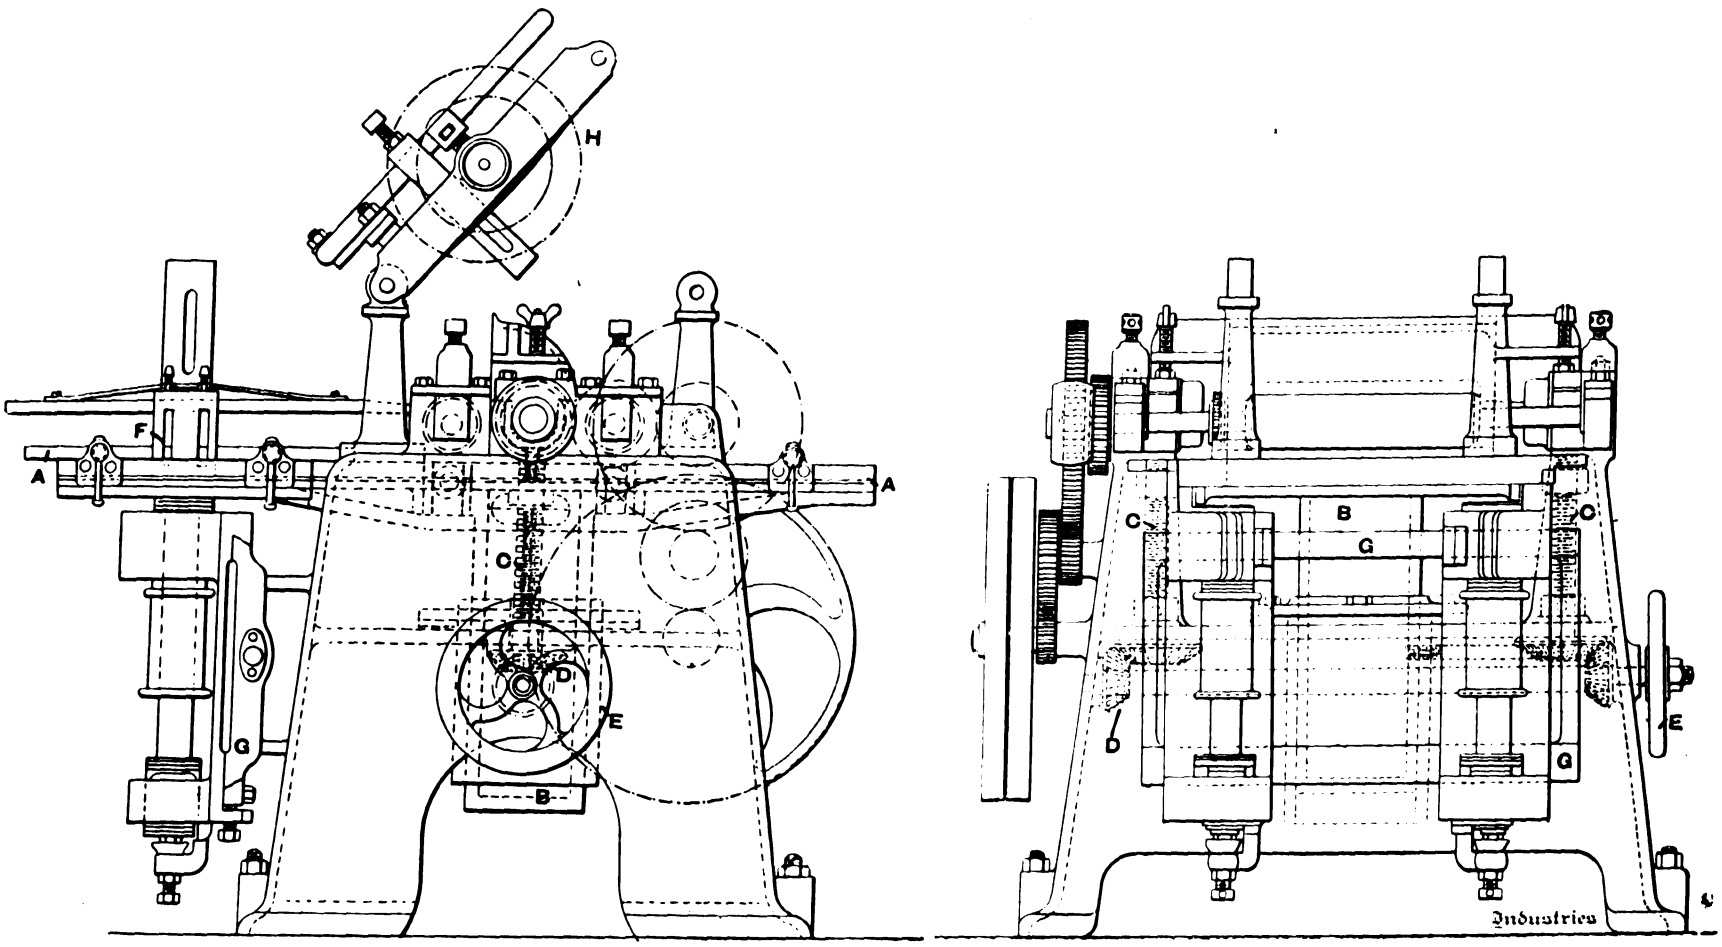

FIG. 1.

MESSRS. ARBEY'S TOOLS AT THE LATE PARIS EXHIBITION.

WE illustrate herewith a parquet machine, exhibited by Messrs. Arbey. Figs. 1 and 2 show front and end elevations, from which it will be seen that the table A is supported by a cylinder B, and can be raised or lowered by means of two screws C, which are caused to revolve by bevel wheels D, actuated by the hand wheel E. The vertical cutters F are driven by half-crossed belts, and may be moved transversely along the slide G, so as to suit different widths of timber. They may also be raised or lowered to suit the varying heights of the table. The horizontal cutters, which are helicoidal and very thin, are a special feature of the machine, and a special automatic apparatus for sharpening the cutters in position without removing them is supplied. This avoids the necessity for setting the cutters after sharpening. The apparatus is shown at H, and may be swivelled into a vertical position, and held there so as to be out of the way when the machine is working. Fig. 3 shows the mode of applying the sharpening apparatus, and is intelligible without further description. Fig. 4 shows the construction of the helicoidal knife, which is made specially by Messrs. Arbey. The machine is very compact, and occupies only a very small floor space. The pressure against the side of the timber is produced by a weighted lever, and this arrangement, whilst giving sufficient pressure, is not so unyielding as the screw arrangement usually employed.

The same firm exhibited in the machinery hall several excellent machines for wood working, but as these present no novel features we shall only mention them here. These included a copying machine for making gunstocks, wooden shoes, and lasts, which will copy four at one operation: it is similar to the machines made by Messrs. Arbey for making gunstocks, and now worked by the French Government in their arsenals at Chatellerault and St. Etienne; two moulding machines, one for straight mouldings and the other for carved mouldings, a type of machine first made by this firm; a large band saw; a copying lathe, for copying objects such as chair or table legs or the handles for coffee-pots; a machine for making wood wool, which we described in *Industries* some time ago (see Vol. V., page 74); boring and mortising machinery, tenoning machinery, and grinding apparatus.

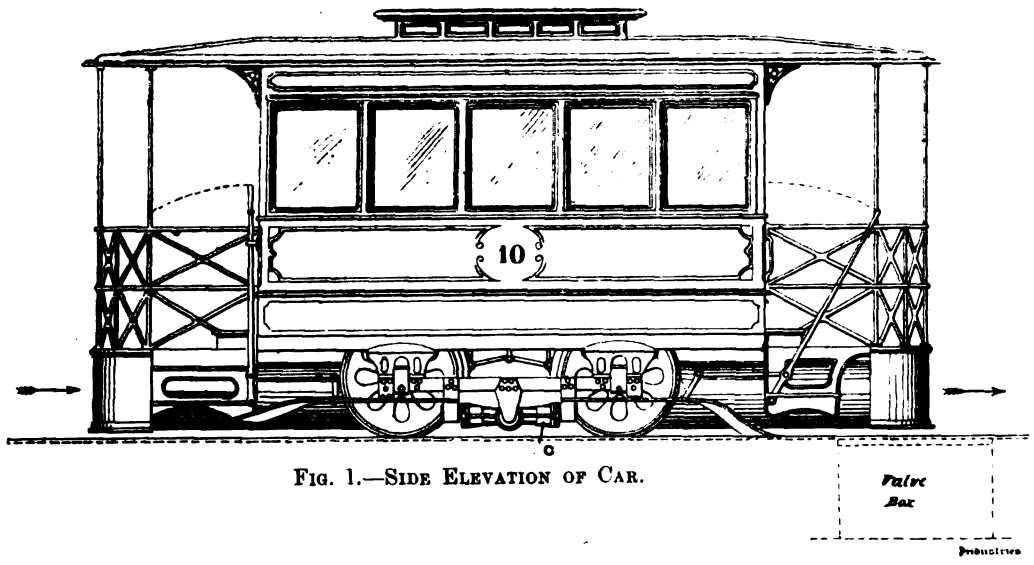

FIG. 1.—SIDE ELEVATION OF CAR.

TRAINING FOR TRADES AND CRAFTS.

BY HENRY DYER, C.E., M.A.

(*Continued from page 195.*)

III.

FOR those who wished to be ranked as tradesmen or craftsmen, there ought to be three grades of examination when they had attained at least the age of twenty-one. The first for those who had been in the workshops for at least five years, and who had attended a few elementary classes in general subjects and in the theory of their special departments. The examination need not be very difficult, either in the theoretical or practical sides, but should be sufficient to test whether the candidates were able to do an average day's work, and at the same time knew the elements of the principles involved. The second grade should have a higher standard in the theoretical subjects, and those who passed it should get off with four years in the workshop as apprentices; while the third should be higher still, and only require three years in the workshop. These two latter examinations would be taken up by those who aimed at being foremen and managers, and who had had special advantages at school or college.

By whom should these examinations be conducted, or, at least, superintended? In my opinion it should be by joint committees of the employers and the employed in the different trades and crafts. For the examinations of the first class a committee of workmen and masters, of the second of foremen and masters, and of the third of special examiners and masters, should be appointed, and thus not only would the entrance to each trade be properly guarded, but, what is of more importance, the work in our technical schools would be kept up to date, and prevented from running to seed among the fads of the teachers. Where the committees found examinations already in existence which met their requirements they should accept certificates from those who had passed them, and not cause new ones to be instituted. Moreover, when a man had been in receipt of at least the minimum standard wage for, say a year after the completion of his apprenticeship, that should be accepted as sufficient proof of his ability as a workman. The work of the committee would therefore be, to a large extent, the testing of credentials, and the influencing of teaching rather than the direct superintendence of examinations. The greatest danger to technical education arises from the fact that instruction is apt to become stereotyped, or the teachers take up a little bit of a subject and exhaust it, and the work is of as little use to the pupils as doses of Greek or Latin grammar. There can be no doubt that, if once we obtained the right men as teachers—men who could really teach, and who had at the same time considerable theoretical and practical experience of the trade or craft—we would have overcome one of the most serious difficulties in the way of the development of technical education. The scientific man, buried in his own abstractions and with no enthusiasm for the teaching of youth, the skilled workman, ignorant of the methods of education, and the artful crammer, who with a minimum of knowledge *passes* a maximum of students, are types of men who have brought technical education into disrepute.

The tendency of some of our modern legislation and custom is to range employers and employed on opposite sides, and questions affecting them are decided, not on their merits, but by a measurement of the force which each can bring into the struggle. This is a barbarous system, and the sooner it is changed the better for all concerned. Instead of having unions of masters to squeeze all they can out of the men, and trades unions to exact all they can from the masters, we ought to have an organisation in which the interests of both employers and employed would be fairly considered. In short, we want a modification and development of the trades guilds of the middle ages, and in this, as in many other things, we find that true liberalism is a return to the customs of our forefathers. The study of the constitution and duties of these modern guilds is beyond my present purpose, but one very obvious function would be the regulation of the admission of members, and the conditions under which the different trades and crafts are to be taught. The trades unions have often been blamed for enforcing their arbitrary rules regarding the number of apprentices to be employed in the different trades, but if they agreed to limit that number by a test of skill and knowledge, and insisted on the employers doing their duty to their apprentices, they would be supported in their position by the public. This arrangement has already been carried out in a few trades, and it has been applauded by all concerned, and been productive of the greatest possible good. It must be distinctly understood, if technical education falls into the hands of paid public officials, and separated from those who are actively engaged in the trades and crafts connected with it, it will become a snare and a delusion; the machinery may be improved, but the true spirit which should be at the bottom of all real developments will be utterly awanting. I have no doubt it will be said that my suggestions are contrary to the accepted doctrines of political economy and the principles of Free Trade. With these I am not specially concerned, and, when they interfere with the development of humanity, I have no hesitation in putting them aside.

In order to give some idea of the amount of theoretical knowledge which I consider necessary in the different grades which I have mentioned, a brief outline may be given of the arrangements which have been made in the Glasgow and West of Scotland Technical College. The evening classes have been arranged to lead up from the ordinary classes of a Board school, and complete courses of instruction, at very low fees, have been instituted in the following departments:—

1. Mechanical Engineering.
2. Naval Architecture.
3. Electrical Engineering.
4. Architecture.
5. Building Construction.
6. Mining.
7. Metallurgy.
8. Agriculture.
9. Chemical Industries.
10. Textile Industries.
11. Art Industries.
12. Commerce.

In each of these departments there are two grades of instruction and of certificates, the junior being within the reach of all ordinary apprentices, and the senior being intended for those who have had better opportunities or have greater abilities. The standard of the junior certificate would, in my opinion, be very suitable for the admission standard to the trades guild, on the theoretical side. On the practical side it would be determined from time to time by the committees of the different trades and crafts.

There is a considerable number of bursaries in the College to assist those who are attending the evening classes, and a few scholarships to take some of the best students from the evening to the day classes, and the governors have also power to remit in whole or in part the fees of artisans and others who are desirous of attending the day classes and require aid for obtaining the education therein provided. In the day classes a course of instruction extending over three years has been arranged in the following departments:—

1. Civil Engineering.
2. Mechanical Engineering.
3. Naval Architecture.
4. Electrical Engineering.
5. Architecture.
6. Chemical Engineering.
7. Metallurgy.
8. Mining Engineering.
9. Agriculture.

and those who complete the course and pass the necessary examinations obtain a diploma and become Associates of the College. The diploma can also be got by those who hold the senior certificate after an attendance of one year at the day classes. Negotiations are now being carried on with the authorities of Glasgow University for the recognition of attendance at the College as qualifying in great part for the degree of Bachelor of Science. When these have been completed we will have an educational ladder which will reach from the lowest class in a Board school to the highest class in the University, and only requiring ability, perseverance, and energy to enable the poorest student to mount to its topmost rung.

The progress of technical education has been very much impeded by the extravagant demands of enthusiasts, and by vague ideas about the necessity of educating the British working men. In my opinion there is far more necessity for educating the British manufacturers, not only as regards the value of improved scientific knowledge, but also in their social duties, and especially those they owe to their workmen. If they clearly recognised the worth of education and encouraged it, the working men would soon take to it, and if they took a friendly interest in the welfare of their workmen we would hear little of strikes, lock-outs, and other labour difficulties. As a matter of fact the extension of labour-saving appliances in those industries in which goods are manufactured on a large scale has in very many cases reduced the workmen to parts of the machines, or to labourers who do unskilled work. For these men, what is wanted, is not so much technical education, which they have no opportunities of applying, but general education which will enable them to escape from the drudgery of their daily lives. This is true to a very considerable extent even with skilled workmen, and therefore the pass examinations which I have suggested should be comparatively easy, and their technical knowledge should be simply intended to enable them to go about their work in an intelligent manner. Their general knowledge should, however, fit them to act the part of good citizens—a matter of greater importance than mere skill in a trade. Opportunities should, however, be afforded to the most intelligent and persevering for passing to the higher grades by means of bursaries and scholarships, but no artificial system should be pursued which took good workmen from the workshop and unfitted them for any other useful work. Our elementary education has produced a large number of men who would not condescend to a good day's hard work, and has overstocked the market with clerks; and, if we do not take care, technical education, so called, will do the same for the more genteel parts of the trades. The majority of those who at present attend science and technical classes do so, not that they may become better workmen, but that they may be relieved from working with their hands almost altogether, and I very much doubt if those who pass the greatest number of science and art examinations are the most expert in the workshop or the most useful in the management of business. The really successful technical education of the future will not be a mere smattering of science combined with a certain amount of practice, but will consist of the highest possible knowledge in special departments, which will enable its possessors to revolutionise old industries or to introduce new ones; and, however much manufacturers may wish to have workmen with a fair amount of scientific training, it is of much more importance to them, at least from their ordinary point of view, to have a few highly skilled engineers, or chemists, or artistic designers, as the case may be. I make these remarks for the purpose of indicating that in my opinion, the future happiness and welfare of the

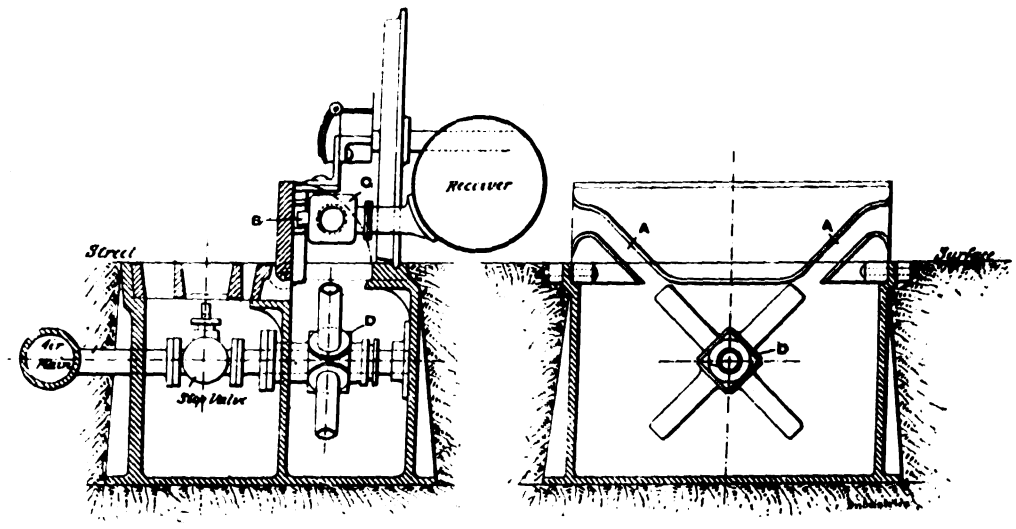

FIG. 5.

FIG. 6.

great majority of the working classes will depend much more on a good general, than on a narrow technical, education; because then, not only will they be able to rise above the mechanical drudgery of their daily work, but what is of more importance, they will, as educated free men, have the determination to withstand the attempts of unscrupulous capitalists to use them as machines for grinding out dividends apart from the consequences either to themselves or to society. It is, therefore, highly necessary that tradesmen and craftsmen should make themselves acquainted with the history of economic ideas, and of industrial and commercial institutions, so that in making arrangements for the future they may be guided by the experience of the past, and be able to rise above the merely selfish class feeling which is too apt to be engendered when only present wants and conditions are considered. They would, among other things, do what they could to assist in the terrible problem of unskilled labour, with its long hours of monotonous, soul-destroying work, or its body-destroying slavery; for if this be not done, the whole movement for the improvement of the position of tradesmen and craftsmen would lead to the establishment of a select body in comparative comfort, and a great mass in the deepest degradation. All real social reform must permeate the whole community, and not create a caste system which, in many cases, would be more heartless than the present.

For some time past some of the trades have been agitating for Acts of Parliament to be passed, requiring that examinations be held to test the fitness of persons holding special positions for the duties they have to perform. For instance, the shipwrights are anxious that a competent professional examination should be required of those in their trade before they are allowed to proceed to sea. A resolution to this effect was adopted at the last Trades Union Congress, as was also another, expressing the opinion that no person should be placed in charge of steam engines or boilers (sea or land) who has not undergone an examination to prove his practical fitness for such employment. Already the Board of Trade has such examinations for navigating officers and engineers of vessels, and no doubt in some respects they have been the cause of considerable improvement. But in this matter, as in almost every other connected with education, the British public has been compelled to worship the fetish "examination." Examinations by themselves generally lead to pure cram; and I am very much misinformed if these Board of Trade examinations are not examples of the most unmitigated cram in existence. They have reared up a class of men who have no object in educating those who come under them, and who are content with simply stuffing them with material which can be conveniently placed on the examination paper. Now such a system not only does comparatively little good, but it also does a large amount of positive harm. It would be rendered quite unnecessary if the arrangements I have suggested were adopted, as each trade would then be directly responsible for the efficiency of its members, and if an Act of Parliament were required at all it would be to compel shipowners and others only to engage those who were able to show that they were recognised members of the trade. Responsibility would thus be thrown on the proper parties, and a more thorough training, both in the theory and practice of their work, insured on the part of all candidates for such positions as I have named, and as a result we would not only have better tradesmen, but also, as a rule, better men.

I have held and expressed these opinions about modern trades guilds for a considerable time, and I am pleased to find that similar ones are held and expressed by those who are intimately acquainted with the organisation of trades unions. Mr. John Burnett, formerly Secretary of the Amalgamated Society of Engineers, now Labour Correspondent of the Board of Trade, says: "Everything is being sacrificed to the cry of 'more work,' and even the character of the workers will suffer as long as this is made the first object. A modern trade guild might therefore fitly consider if the old apprenticeship system might not be revived with interest and advantage to all concerned. The division of labour is now carried out to such an extent that the good all-round workman of the old-fashioned stamp is more and more difficult to meet with. Employers frequently complain that they cannot obtain such men, oblivious of the fact that their method of using boy labour is entirely to blame for the evil. The boy is not now trained that he may become a generally skilful workman, but that he may produce as much profit as possible to his employer. To make the boy a master of his trade is no part of the bargain. Such guilds might also take up the kindred subject of technical education, so closely allied with that of the workshop training of the young. Even apart from the employers, it would be to the advantage of the unions to assist the spread of technical knowledge among their members, by raising scholarships and establishing classes to develop among their members the scientific knowledge of their trades. To give to them the brains as well as the manual skill of their industry, will not only do much to keep down the number of their unemployed and increase their membership, but solidly impress upon the minds of employers that unionists are indeed the pick of British artisans. This may be deemed a somewhat Utopian idea, but in an age when the increasing severity of competition for the work of the world makes absolute co-operation between capital and labour more and more a national necessity, I hope to see the practical accomplishment of this ideal."*

The first step necessary for the carrying out of the proposals I have made is for a joint committee of the employers and the employed in each trade or craft to meet and arrange the conditions under which it shall be learned, both as regards its theory and its practice. These being settled both parties must be bound to do their best to enforce them. The masters would insist on their employés, and the trades unions on their members, conforming to them. Of course it would take some little time before they could be put into full operation, but when once they were we would, with slight modifications and extensions in our present educational arrangements, have all we require in the way of training for trades and crafts, and that without the aids of special Acts of Parliament and of institutions and machinery which would involve an immense expense to the country. If the work were properly carried out we would also have, what is of more importance from every point of view, a manly enthusiasm and pride in the welfare of all connected with trades and crafts, and a healthy social spirit, which never allowed selfish or class interests to interfere with those of the community and the State.

* "Claims of Labour," Lectures, p. 37.

LOW-PRESSURE COMPRESSED AIR TRAMCAR.

THOUGH we are well familiarised with the iron roads in our streets, and look on the constant service of tramcars in our main thoroughfares as a necessary part of everyday life, yet after its introduction the system has remained practically what it was at the outset. Nothing has been generally adopted to supersede horse-flesh for traction, though the field is such a good one. It can only be surmised, therefore, that the tramway companies have found some practical defects in whatever has hitherto been brought to their notice. A new form of mechanical plant for the purpose is now bidding for a share of patronage. It is connected with the use of a low-pressure air tramcar, of which Messrs. Hughes & Lancaster, of Chester, are the makers. A few days ago this firm gave a demonstration of the system, which appears to possess many valuable features.

It may be premised that the use of compressed air is not new in street car traction; but previous attempts have always been in the direction of high pressures. If they have failed, it has not been for mechanical, but economical, reasons. On Colonel Beaumont's plan it was sought to use a pressure of about 1,200lb. on the square inch, and carry a store for a complete journey out and home to the depôt. Such a high pressure necessitated a considerable receiver thickness to withstand it, and this signified deadweight to be transported at all times. The receivers, too, had to be large enough to provide sufficient air for a long journey. To extract as much advantage from the system as possible heating apparatus was employed. To satisfy all these conditions a separate car became compulsory, and this had to be made heavy enough to give the required adhesion to the rails and draw a fully loaded car up the steepest incline. Thus we come to the same drawbacks as the ordinary street locomotive, with the expensive permanent way to support it. Moreover, as there is a certain loss of energy in compressing air, in practice, this loss becomes intensified as we reach higher pressures. When, however, a little above 10lb. pressure in the receivers is sufficient to propel a car, a great weakness in the system becomes apparent—enough, in short, to make all the difference between success and the reverse. Much the same may be said of the Mekarski plan, in which a pressure about half that named is used. On the low-pressure system, which has been established by Messrs. Hughes & Lancaster, a maximum of 170lb. on the square inch is all that is employed to do the work. Instead of carrying on the car the air wanted for a whole run, the receivers are only charged for a very short distance, the average being about a mile. A fresh

Digitized by Google

supply is picked up *en route* from a main pipe laid under the roadway with branches in boxes alongside the line. The lids of these boxes are level with the road, and present no obstruction to ordinary traffic. For some distance on each side of them the rail is double grooved. A driver, on approaching one of these charging stations—slowing down somewhat as a matter of course—uses a lever standing on each car platform to drop a plough into the second groove. The box lid is lifted on its hinges, and kept up by the car body. There are two slots A (Fig. 6) on the under side of this lid, into the entering one of which a pin B on the double-ended car valve C engages. The valve arm, by the movement of the car, is brought directly opposite one branch of the four which radiate from the centre supply valve D in the box. It clasps bodily the branch presented to it, and in the vertical position (Fig. 3) full feed takes place, both valves being then open. A few seconds suffice for a moderate charge, but generally a stop will be made, and boxes will be fixed conveniently for so doing. As the car passes onwards communication ceases, the two arms of the car valve C become horizontal again but at opposite points, while the valve D on the main has passed through 90° only. Both are then shut, and left so that a similar operation may be repeated, and the lid falls into its place again. The series of operations after the first are therefore quite automatic.

Our illustration, Fig. 1, represents the car with which the experimental trials have been made. Figs. 2, 3, and 4 show the entering, full open, and leaving positions of the car and supply valves C and D. Fig. 5 shows a transverse section of the supply-main culvert and valve box, and Fig. 6 shows a sectional elevation of the valve box with the lid open. The car is self-contained, the motor being attached direct to the axle and with all the air receivers out of sight. It moves without any visible agency whatever. We had on the occasion referred to an opportunity of a short trip of half a mile on an incline of 1 in 45. The car appeared to behave very well and be easily under control. As, however, the usual traffic had to be contended with, we are compelled to refer to the extended report made by Professor Unwin for complete results.

First, however, we may inquire what leads to a saving over anything of the kind to which we are accustomed. What is the cause of the greater efficiency claimed? It will be observed that there is a minimum of deadweight in the apparatus employed. The air reservoirs have only a thickness of ⅛in., owing to the low pressure contained in them. The weights are:—Car, 1 ton 19 cwt.; machinery, 1 ton 15 cwt.; passengers, 1 ton 15 cwt.; total, 5 ton 9 cwt. This gives a proportion of machinery to the total of only one-third, whereas with steam trams the locomotive alone may weigh probably 12 tons, giving a dead load out of all proportion to that of the car and passengers—say, of four tons. Again, there is more economy in employing one central source of power and distributing it through several machines not all making the largest demand at any one time, than in keeping each one up to its full capacity whether it is requiring the same or not. It is to such causes as these, then, that we must look for the successful results put forward, viz., that only one-third to one-sixth the usual haulage work is done on this system. Opposed to this gain there is the thermal loss due to compression of the air to be taken into account, and the friction and leakage being spread over a range of pipes, but the advantages appear to much more than counterbalance the drawbacks.

The trials have all been conducted with an experimental car, which was not built for the purpose. A certain leakage, therefore, occurred, which will no doubt be greatly minimised when the receivers are built in the car itself, and the motor improved, as a result of the experiments. It has been found by Professor Unwin that a fall of only 7° in temperature was evident in the receivers after a run, heat being supposed to be abstracted from the atmosphere through the thin casings. The professor's results are therefore calculated on the assumption that the expansion of air in the receivers is isothermal, and the curve showing the work done hyperbolic. He assumes the car resistance at 27lb. per ton, and from his experiments deduces 12,000 foot lb. of work for every pound of air used. We give his results:—

Gradient.	Resistance in lbs. of six-ton car.	Initial pressure above atm. lbs. per sq. in.	Final pressure above atm. lbs. per sq. in.	Pounds of air used in run.	Work in traction per lb. of air used, ft. lbs.	Distance run before stopping, in feet.
Level	·162	170	18	78·77	14,510	7,055
1 in 150	252	170	28	73·60	13,790	4,028
1 in 75	342	170	38	68·42	13,010	2,603
1 in 50	430	170	48	63·24	12,340	1,814
1 in 25	698	170	76	48·72	11,020	769

PUMPING MACHINERY FOR JAPAN.

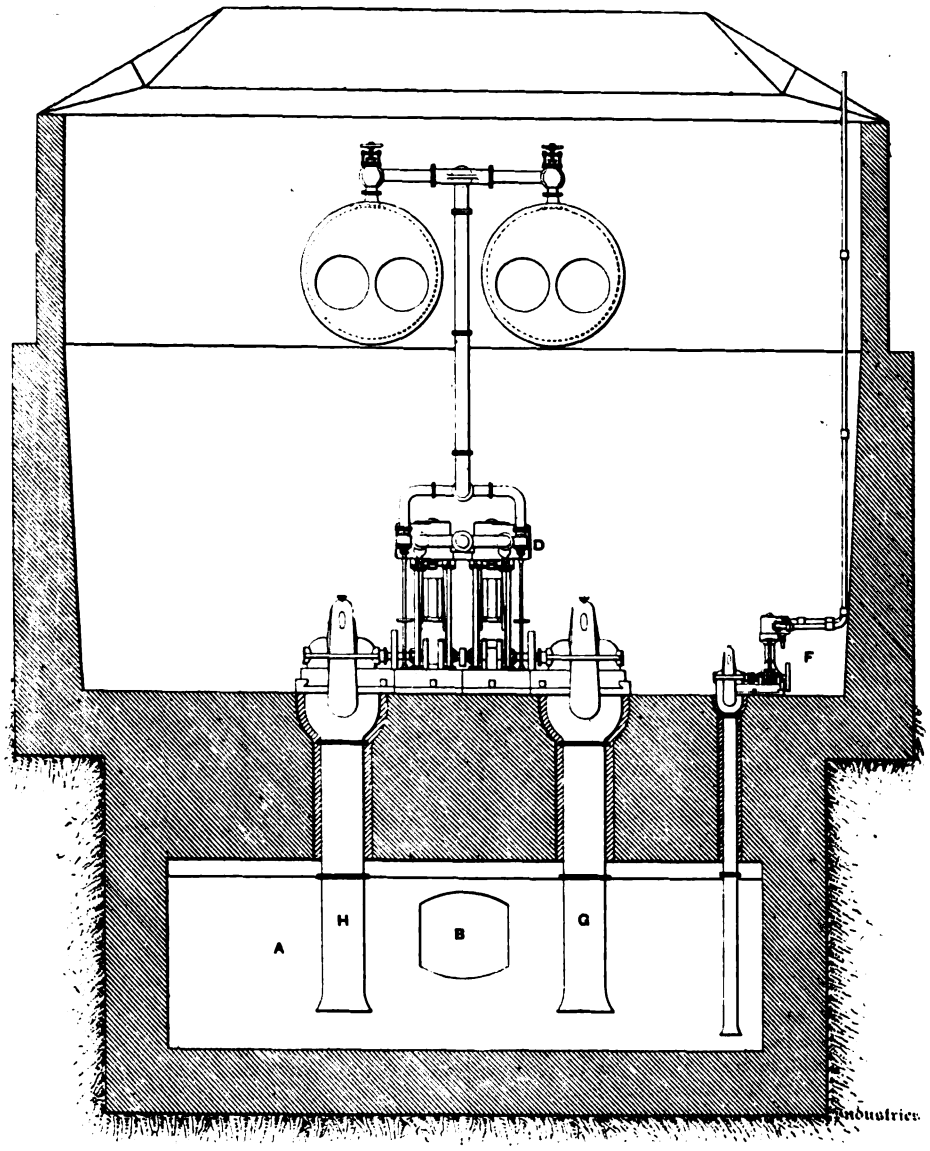

FIG. 1.—TRANSVERSE SECTION OF ENGINE AND BOILER HOUSE.

These are for level or rising gradients. On the falling gradients the air may be shut off, or the motor reversed, so as to partially recharge the reservoirs and give a brake action. It may be added that the air cylinders have a capacity of 52ft., the average speed of the car being 9 miles per hour. As much, however, as 15 miles an hour has been recorded.

Messrs. Hughes & Lancaster themselves compute that, with coal at 10s. per ton, on a line like that at Chester, the cost of fuel would be ¾d. per car mile, or even less. It will be gathered, therefore, that there is every likelihood of this low-pressure system being introduced to the public notice in a manner to test it thoroughly. Its advent will be watched with much interest.

PUMPING MACHINERY FOR THE JAPANESE GOVERNMENT.

WE have on numerous occasions set forth before our readers information relating to the astonishing progress made by Japan. Notwithstanding the great strides made by the Japanese Government and people in various directions, with the view of making their interesting country the "Britain of the East," progress is still being continued, though probably in a more guarded and careful way than heretofore. As an example of recent progress in Japan, we illustrate above and on pages 269 and 276 a dock pumping plant which has been recently constructed for the Japanese Government, and is intended for a new dock now being built at Hiogo. This dock is of large size, and will be capable of taking in steamers of the largest tonnage ever likely to require accommodation in that port. The dock is being erected and will be worked under the supervision of Mr. Miyabara, a Japanese engineer of considerable experience, who was for some time engaged in this country in surveying steamers built for his Government. The dock is being constructed of stone of the usual form, and the pumping machinery we are about to describe is arranged to empty it in from two and a half to three hours. The whole of this machinery has been designed and constructed by Messrs. W. H. Allen & Co., engineers, York Street Works, Lambeth, London, and is capable of discharging 7,000 tons of water per hour when both pumps are at work Referring to our illustrations, Fig. 1 (above) and Figs. 2 and 3 (on the opposite page) represent a transverse section, a sectional elevation, and a sectional plan respectively of the engine and boiler house, while Fig. 4 (page 276) shows a general view of the engines and pumps. It will be seen from the illustrations that a pair of centrifugal pumps and a pair of inverted vertical engines are neatly arranged and affixed to a continuous and massive bed-plate. The pumps are arranged on the outside, right and left, and the engine crank shaft is extended on either side to carry the pump discs. The joints of the pump casings are in a horizontal plane, and therefore the discs can easily be examined. The lower parts of the pump casings, together with the suction and delivery pipe orifices, are made to form part of the bed-plate, and the number of joints are thus reduced to a minimum. The pump discs are each 5ft. diameter, and the suction and delivery pipes 2ft. 3in. diameter. The engines have cylinders 18in. in diameter, with a stroke of 16in., and are fitted with variable expansion gear. The starting gear is specially arranged so that the engines can be operated from above or below. The makers have had a very large experience in this class of work, and the engines and pumps embody all their latest improvements, and are constructed with all their usual care and finish. The steam for the engines is derived from two Lancashire boilers, 6ft. 6in. diameter and 28ft. long. As above stated, the whole of the machinery, including the small pumping engine for draining the dock from any slight leakage, has been supplied by Messrs. W. H. Allen & Co., and we have no doubt, from our knowledge of the work done by this firm, that the plant will give satisfactory results.

FOREIGN INDUSTRIES.

(From our own Correspondents.)

(FOR LATEST TELEGRAPHIC DESPATCHES SEE PAGE 273.)

PARIS, 18th March, 1890.

IRON.—Business in iron has certainly not improved in the last week. Here in Paris there is hardly anything doing, and there are no signs of a better trade in the near future. That the merchants have but little confidence in the situation is shown by the fact that in three weeks they have let the price of bars fall from 172s. to 156s. a ton. The state of affairs is less discouraging in the provinces, but the demand is everywhere fallen off. For the present, and for at least two months to come, manufacturers have plenty of work in hand, but fresh orders are becoming scarce. Were the coal market less firm prices would give way. The imports of Spanish ores by the port of Dunkirk amounted last year to 249,857 tons against 173,956 tons in 1888.

COAL.—The coal question continues to afford cause for much anxiety, inasmuch as the attitude of the miners is uncertain. The conflict begun in England has given strength to the agitation which the Socialist organisations are striving to keep up among the colliers, and the partial strikes which are almost daily announced from the Saint Etienne district show that not much is needed to fan the spark into flame. Meanwhile the market, in spite of the fact that the supply is now equal to the demand, remains very firm, and even shows a rising tendency. Thus coke, the minimum price of which is, in the North, 28s. a ton, is being sold at 29s., and it is expected that 30s. will be asked before the end of the month. Coal for industrial purposes has advanced 1s. a ton within the last few days. Colliery proprietors are unwilling to contract far forward at the current rates. One company, which is selling its coal at 16s. and 17s. in small lots for prompt delivery, refused last week an offer for 20,000 tons at the price of 15s. 2½d. a ton.

THE NITRATE OF SODA TRADE.—The statistics of the trade of the port of Dunkirk in 1889 show continued and rapid growth of the imports of nitrate of soda, the use of which as a manure is steadily increasing. The quantity entering the port last year amounted to 159,310 tons, against 141,514 tons in 1888. When the ships now being built on the Clyde specially for this trade are ready we may look for much larger returns. Agriculturists are beginning to perceive their opportunity afforded by the present depressed markets, and are buying freely. The latest quotations at Dunkirk are £7 12s. to £7 15s. per ton.

STRIKES.—From statistics recently collected it appears that the industry most subject to disturbance from strikes in France is that of the textile manufacturers, in which 39 per cent. of the total number occur. Next follow the coal mining and iron and steel making industries with 17 per cent., and the building and joinery trade with 15 per cent.

ELECTRIC LIGHT AT ST. OUEN LES DOCKS.—"La Société pour la Transmission de la Force par l'Electricité" has installed at St. Ouen, near Paris, a large station for supplying a portion of Paris and the sub-stations of the neighbouring villages, Asnières, St. Denis, and St. Ouen, with electricity. This station comprises four groups of two Roser boilers giving 16,000 kilogs. of steam per hour, four groups of coupled cylinder Corliss engines of 300 h.p. each, seven Marcel-Deprez dynamos giving 2,400 volts and 30 amperes. This current will be transmitted to the sub-stations, and there transformed to be distributed at 100 volts. The necessary electrical energy for exciting the high-pressure dynamos for lighting the works will be furnished by four Hillairet dynamos of 250 amperes, 110 volts, one Marcel-Deprez dynamo of 500 amperes. A battery of Laurent Cély accumulators of 500 kilogs., constructed by "La Société du Travail Electrique des Métaux," will complete the installation now in progress, and on which we shall have more to say when working.

INTERNATIONAL TELEGRAPHIC CONFERENCE.—It is proposed to hold an international telegraphic conference in Paris this year, and invitations have been sent to all the telegraph companies in the world. The date of the conference is not yet fixed.

BERLIN, 17th March, 1890.

EMIGRATION FROM GERMANY.—According to the official statistics, 2,765 emigrants left Germany during January. Of this number 500 came from Posen, 340 from Pomerania, 265 from West Prussia, and the remainder from the various States of Southern Germany. Emigration is slightly on the increase.

A TELETHERMOMETER.—Herr Lüders, of Görlitz, has recently invented a thermometer for ascertaining the temperature of the depths of the sea. Its action depends on the different electric conductivities of substances at different temperatures. Inside a glass tube are fixed a spiral iron wire and a bar of carbon, which only touch at their lower ends. Their other ends are connected to copper wires, which constitute an electric circuit, and in this circuit there is a galvanometer which indicates the differences in the current due to the variations in the temperature of the contents of the glass tube.

COAL.—Though the demand for house coal falls off as the summer approaches, the markets of Upper Silesia lose nothing in activity, the shrinkage of business in that direction being compensated by expansion in others. Thus, in consequence of the high prices of Westphalian and Saarbrück coal, large consignments of Upper Silesian produce are being sent to Stuttgart. According to a Silesian journal, three firms of coal merchants control fully 70 per cent. of the production of the Upper Silesian pits. The demand for coke being still in excess of the supply, production is being pushed on with the utmost vigour. New ovens are being built in many places.

LABOUR.—The meeting of the Labour Congress seems to have given a fillip to the agitation which has of late been increasing among all classes of operatives. There is no great industry, and hardly a trade, that is not seriously disturbed by demands for higher wages and shorter hours. Last week we had here in Berlin meetings of the persons occupied in the house furnishing trades, with a view to united action in a proposed attempt to better their position by a strike. Also the coppersmiths, who obtained last year a reduction of their working day to ten hours and a substantial rise in wages, are agitating for further changes in the same direction. In the case of these metal workers, the questions in dispute have been submitted to a Board of Arbitration chosen by both parties. Strikes are reported from all parts of the country. The strike of coal miners in England has had a powerfully encouraging effect on the leaders of the labour movement in this country. By the express desire of the Emperor, overtime is prohibited in the Spandau cartridge factory, and the length of the working day fixed from 6.30 a.m. to 8 p.m., with the usual periods of rest for meals. This is a reduction of from 1½ to 2 hours a day.

FLAX AND YARNS.—At Trautenau the demand continues brisk for yarns, full rates being readily paid by buyers for both tow and linen yarns. The latter are for the moment scarce in the market. At Bielefeld business is slack in the coarser numbers; but the finer sorts are quickly bought up. The imports of linen yarns in the first month of the current year amounted to 17,988 cwt. against 19,656 cwt. in the same month of 1889

THE CHEMICAL INDUSTRY.—At the general meeting of the Silesian Association of Chemical Manufacturers, held on the 10th inst. at Saarau, a dividend of 8 per cent. on the business of last year was declared, against 7 per cent. in 1888 and 6 per cent. in 1887. The state of the industry was reported favourable and the immediate prospects encouraging. The gross profits for the last three years were £47,250, £43,300, and £35,800 respectively.

NEW SMOKELESS POWDER.—Herr Kolk, a chemist employed in the Chemical Institute at Bonn, has invented a new smokeless powder, which, it is said, has given excellent results in trials recently made at Cologne. The invention has been offered to the Prussian Minister of War, who has ordered an investigation of its merits to be made.

VIENNA, 17th March, 1890.

BEER.—The total quantity of beer produced by the Vienna breweries during last year amounted to 2,451,652 hectolitres, or an increase of 90,000 hectolitres upon that produced in 1888. The quantity exported, chiefly to Paris and Berlin, showed an increase of barely ½ per cent.

ELECTRICAL ENGINEERING.—The increasing demand for the electric light in Vienna makes itself more clearly felt daily. Various companies already announce that the present central stations are insufficient for the requirements. The Wiener Electricitäts Gesellschaft has, therefore, decided to augment its capital by 2,000,000fl., to increase its plant by 2,000 h.p., or 24,000 glow lamps. The firm of Siemens & Halske are about to erect a new central station in Bezirke. The town of Bielitz, in Schlesien, has decided to adopt the electric light. The first place to be thus illuminated will be the theatre.

THE COAL MARKET.—The extraordinary animated coal traffic on the Bohemian railways is shown by the reports issued last week, and mentioned in my last letter. The accompanying tables represent the amount of coal in tons carried by the undermentioned railways for the months of February, 1889 and 1890, and also the amounts carried in the first two months of above-mentioned years respectively:—

	Feb. 1890.	Feb. 1889.
Dux Bodenbach Railway	152,524 tons ...	89,413 tons
Prague Dux Railway....	102,511 „ ...	70,535 „

In the first two months the traffic was as follows:—

	1890.	1889.
Dux Bodenbach Railway	319,211 tons ...	193,530 tons
Prague Dux Railway....	213,800 „ ...	169,122 „

The market continues more animated as the shipping on the Elbe has already been reopened, and prices tend to increase steadily. With respect to the high coal prices, the increase on the State railways amounts to 250,000fl.

THE IRON MARKET.—The demand for iron remains unchanged. The pig iron market is firm, and the production already greatly exceeds that of the corresponding period of last year. Works for refined iron are very busy, especially in the manufacture of rails and sleepers. Locomotive and waggon works have sufficient orders to last for several years. The State Railways alone have recently ordered 114 locomotives and 1,000 waggons, to be constructed during the next year. The Steyer manufactory of arms is now producing 45,000 rifles monthly. Ganz & Co., of Budapest, have resolved to pay a dividend of 70fl. per share, or 17·5 per cent.

BRUSSELS, 18th March, 1890.

THE COAL MARKET.—The state of the coal market is uncertain, and the buyers and sellers of coal and coke are waiting to see what will be the result of the strike movement in England. The price of coking coal remains firm at 22fr. in the Centre, but a great number of producers, especially near Charleroi, are asking 23fr. Coke is firm at 35fr., and briquettes at from 23fr. to 25fr., according to quality. For *fines demi-grasses* the price is somewhat variable, and transactions may be made at anywhere between 15fr. and 18fr. During the past week the State railways carried 29,564 waggons of fuel, as compared with 23,259 waggons during the corresponding week last year. The Association of Coalowners of Charleroi and Basse-Sambre have petitioned the Minister of Public Works with regard to the delay in the completion of the Charleroi and Brussels Canal.

THE IRON TRADE.—The price of raw materials causes some difficulty to the producers of pig iron. It is proposed to form an association with the coal owners, for the purpose of arriving at some method of carrying on business. At present there are plenty of orders being offered at slightly reduced prices, but if these prices were agreed to there would be no profit for the ironmaster. There are quite a number of large orders to be placed for girders and joists. In merchant bars the former activity has not entirely returned, but it is expected that some orders will be placed shortly. According to the official statistics of the production of iron in Belgium during 1889 it appears that the output of pig iron has been greater than in 1888, but the manufacture of refined iron has decreased slightly. The Haurez multitubular boiler, which was put down at the works of the Société de l'Alliance, has proved so successful that the company have ordered two more from Messrs. Zimmerman, Haurez, & Co., of Monceau-sur-Sambre. During the fifteen months that the boiler has been in use no repairs have been made to the tubes or any other part, and no encrustation has been formed.

THE GLASS TRADE.—The exports of window glass from Belgium are decreasing. The exports to the United States have fallen from 1,700 tons to 245 tons during the months of January, 1889 and 1890. However, the exports of the same to England have increased from 2,420 tons to 3,652 tons.

FLAX.—At Ghent the sales of Russian flax and tows have been of no importance, and the prices have not changed. As regards home-grown flax and tow the prices have been firm and the demand active. The current sales of thread are satisfactory, and sufficient to maintain the prices.

DÜSSELDORF, 18th March, 1890.

COAL.—The declaration of the threatened great strike of coal miners has had a bad effect here in encouraging the colliers to persist in their demands for another great advance in wages and a further reduction of the hours of labour. The want of unanimity in the councils of the men is, however, becoming more marked. The moderate party is rapidly gaining adherents, so that it is tolerably certain that the final terms will not include so exaggerated a claim as a rise of 50 per cent. in wages. It would not be risking much to prophesy the preservation of peace by the concession of another ten per cent. advance. The steadiness of the market indicates a belief that prudent counsels will prevail. The syndicate of coal merchants trading with Holland and Belgium, formed a week ago, has already dropped out of existence. There were too many abstentions to admit of success in practice. The export trade in coal has recovered its former life and vigour. The total quantity of coal and coke exported in the first month of the current year amounted to 840,277 tons, against 815,210 tons in the same month of 1889—an increase of 3·1 per cent. The imports for the same periods were 760,358 tons, against 648,146 tons—an increase of 17 3 per cent. This increase is, however, confined to lignite, coke, and briquettes. The quantity of coal received was considerably less than in January of last year.

IRON.—Throughout the last week business was quiet in every branch of the iron market. Buyers manifested the utmost unwillingness to enter into fresh contracts, and as some of the merchants were offering iron, both crude and finished, below manufacturers' prices, the tone of affairs was somewhat weak. But since it became known that the English coal miners had turned out on strike a firmer tone has prevailed. English competition had begun to press heavily upon German trade, and consumers were relying on this to bring down the price of German iron. This influence will be considerably modified by a large increase in the cost of fuel in England. The demand for joists increases as the spring advances. Plates are still actively dealt in. But wire is neglected. The lowest tender for 2,470 tons of steel rails for the Magdeburg railway was received from the Bochum Verein für Bergbau und Gusstahl-fabrikation; the offer was 165s. a ton at the works. For Breslau, a Silesian firm tendered 166s. at works. Founders have plenty of work, and the greatest activity exists at the machine shops.

THE GLASS TRADE.—At a general meeting held the other day the syndicate of German lamp-glass manufacturers was prolonged for another year, and a resolution was passed to announce immediately a considerable addition to the current prices and to take into consideration a further advance to be announced later.

ELECTRIC STREET TRAMWAYS.—The commission appointed by the Halle municipal authorities to examine a project for substituting electric for horse traction on the street tramways has reported favourably concerning the scheme.

LILLE, 18TH MARCH, 1890.

IRON.—The iron market is much less animated than it was a few weeks ago. Consumers refuse to believe that the present prices can be long maintained, and they are confirmed in their opinion of the tendency of trade by the increasing weakness of the Paris markets. Notwithstanding the growing scarcity of fresh orders, however, the manufacturers hold their ground firmly, the determining influence in their case being the high prices of coal and the uncertainty of the situation relatively to the cost of labour. No. 2 bars cannot be bought under 160s. a ton in lots of ordinary importance. For common plates, which continue in fairly brisk demand, the current quotations are from 192s. to 200s. The supply of coal to the ironworks is now sufficient.

TEXTILE MANUFACTURES.—The last week past was a period of considerable activity in the linen goods trade of Armentières. There have been fewer buying agents in the market, but orders received through the post have been numerous. The turnover for the week was greatly above the average of the last three years, season for season. This satisfactory state of things has brought about a cheerful tone. For the moment the demand is sufficient to absorb the whole of the production. The woollen goods trade is reported from Roubaix to be quiet, as usual at this time of the year. Business in the raw wool market is lifeless, speculative transactions in futures being almost *nil*.

FLAX AND YARNS.—There is an eager market for fine home-grown flax. The quantity on offer being small, spinners have some difficulty in supplying their wants. It is almost needless to add that prices are very firm, with an upward tendency. More business is being done in Russian, and prices are turning in favour of sellers. Tows are but little inquired after. For yarns the market generally is quiet, but the finer numbers are in demand. Slightly higher prices have been paid for some lots. There is a brisk current of business in jute yarns. The fine and medium sorts are very firm in price; the coarser sorts, being less inquired after, are easier.

AMSTERDAM, 17TH MARCH, 1890.

HOLLAND AND THE INTERNATIONAL LABOUR CONFERENCE AT BERLIN.—The Dutch Government has appointed its Minister at Berlin, Sir F. P. Van der Hoeven, Dr. F. J. W. G. Snyder van Wissekerke, a high official of the Ministry of Justice, and Mr. H. W. E. Struve, Labour Correspondent, to be its delegates at the Berlin Conference. These appointments have not given general satisfaction. The Socialists wanted someone specially representing their extreme views to be sent to Berlin, and the Society for the Promotion of National Industries has petitioned the Government for the delegation to the German capital of two or three large employers of labour rather to assist the official delegates and enlighten them than to act as delegates themselves. The Government does not seem willing to accede to this request. In the Lower Chamber the Ministers of Foreign Affairs and of Justice have entered into a few particulars concerning the instructions given by them to the Dutch delegates before their departure. The former said that the Government readily appreciated the high economic and social import of this conference, yet thought it wise for the Netherlands to observe a policy of prudent reserve in questions perhaps involving the free action of the kingdom. Therefore certain reservations have been made in the letter accepting the German Emperor's invitation. The Minister of Justice added that the Dutch delegates have been instructed not to bind Holland in any way by subscribing to international legislation concerning factory labour of adults, whilst adhering to our recent statute regulating the work of women and children in factories and workshops. The Government is certainly of opinion that women and children ought not to work in mines, but Holland has not much interest in this particular question, for her mines are few, and women and children are not employed in any of them. As for adult labour, a great reserve is doubly necessary in a country like Holland, because the condition of the labouring classes here is not sufficiently known, and for that very reason is now being inquired into by a Royal Commission. Concerning Sunday labour the Dutch delegates will have to point out that their Government is sincerely desirous of curtailing it as much as possible, and has shown that desire by practical legislation. Sunday labour of young women and children, unless necessary, is already forbidden on a Sunday in Holland by statute law, whilst the postal and telegraph business on Sundays has been much curtailed recently. The train service on railways might also be reduced, but international action is necessary as regards through train services.

ELECTRIC LIGHTING AT ROTTERDAM.—The communal authorities at Rotterdam are studying the question of lighting the city by electricity. Different systems are being tested. Companies are already at work, but all under immediately terminable contracts.

GOLD IN FRENCH GUIANA.—A company has been started, with a capital of £100,000, at the Hague, for the acquisition of an auriferous territory in French Guiana, known as the Placer National, and having an area of 80,000 acres. Only one-fortieth part of the property has been worked by a French syndicate, and it is said that that one-fortieth part contains sufficient alluvial gold to repay the whole capital of the company nearly three times over. One of the directors is the French civil engineer, M. Soupé, Government contractor of the first railway in Tonquin.

COPENHAGEN, 15TH MARCH, 1890.

A FREE PORT FOR COPENHAGEN.—The Committee of the Landsthing appointed to consider the Government Bill for establishing a free port near Copenhagen has reported in favour of the measure, expressing the opinion that, in view of the competition in the Baltic, the proposed port would greatly benefit the trade of Copenhagen. The Committee also agreed to the proposal for placing the construction and management of the port in the hands of a joint-stock company, and recommend the abolition of harbour dues on the earliest opportunity.

THE PRODUCTION OF METALS IN SWEDEN DURING 1888.—The following list gives the production of metals, &c., in Sweden during 1887 and 1888:—

		1887.	1888.

MADRID, 17TH MARCH, 1890.

GLASS MANUFACTURE.—One of the most promising industries in this country is glass manufacture—that is, those branches of it which do not require skilled workmen in any great number. Plate glass is very little used in this country on account of its great cost, but if sold at the prices which rule in England and Belgium the demand would increase very greatly, and any establishment would prosper. Excellent sulphate of soda is found in mines near Madrid, and sand is as plentiful as in most places where plate glass is made The drawback of expensive fuel could be compensated by the advantages of a large local market and cheap labour, and perhaps also by the use of water power.

THE PRICE OF ELECTRIC CURRENT AT MADRID.—The Electricity Supply Company in Spain have issued their circular advertising that they supply electricity for light and power. The prices fixed are one halfpenny per lamp hour of ten candles, and 1s. 4d. per 1,000 watt hours. Of course these prices are high, but they have been fixed in strict accordance with the price of gas, viz., 9s. per 1,000ft. It is supposed, however, that these prices cannot be maintained for any time, as there are many isolated installations in which the real cost of electricity will become evident, and all kinds of competition will ensue. One of the small theatres has an installation of its own with an excess of power, and it supplies electricity to the shops situated in the same street at different prices, according to the number of lamps; the profit on the current supplied pays for the cost of the theatre lights, which amounts to about £3 to £4 per day.

THE TRANSATLANTIC COMPANY.—This great business, which has in its hands the carrying of the whole of the foreign mails of the country, has issued a report, which is not particularly detailed. The directors have to stick to generalities in order to justify their inability to pay any dividend. They boast of having improved their fleet considerably, and hold out hopes for the future prosperity of the Company. It is, however, likely that the present state of affairs will go on indefinitely, for many unsubventioned lines of steamers are taking away much of their traffic.

NEW YORK, 8TH MARCH, 1890.

THE COAL MARKET.—There has been no improvement in the outlook in the anthracite trade. Prices have fallen and the competition between the individual operators is damaging the trade. It does not look as though the proposed restriction to two million tons for the current month would improve the trade in the slightest. For the past year the average working time throughout the coal districts has been about two-thirds of the full time; but the stocks are heavier and the prices lower than they were a year ago. At the same time the expense of stopping for a few days in the week has been heavy, both to operators and miners. Unless some means can be fixed upon for absolutely stopping the production for a time, there seems to be no prospect of the market again recovering a healthy tone.

THE IRON AND STEEL TRADES.—There is little doing in iron. The cost of raw material has advanced much more than the selling prices, and it bids fair to be still higher in the near future. Pig iron has shown a declining tendency lately. Foundry irons are firmer, but there is no demand of any importance. In manufactured iron the demand is barely sufficient to keep the mills going. Old orders are nearly finished, and some mills are beginning to lower their prices. There is a little more inquiry, and at the lower prices there is a probability that a number of good orders will come in.

FREIGHT BLOCKS ON THE AMERICAN RAILWAYS.—The freight blocks on the various railroads are the most serious ever known. On the Pennsylvania road all the yards from Pittsburgh to Jersey City are crowded with loaded cars, and there is no certainty when any of them will be moved. This is due to the unusually heavy shipment of freight of all kinds. Not only are the cars loaded, but the freight depôts are crowded to the roofs. The coke manufacturers are great sufferers on account of this condition of affairs. Nearly all the cars that have been recently loaded at the coke works are still standing in the yards waiting to be moved. The coke houses are filled to overflowing, and the works are consequently unable to run more than four or five days a week.

ELECTRICITY AS A MOTIVE POWER.—Commissioner Mitchell, of the United States Patent Office, has given an important decision by refusing to grant a patent to M. C. A. Faure for a patent for new and useful improvements in the application of secondary electric batteries as a motive power for the propulsion of vehicles. It was urged on behalf of the applicant that he was the first, practically and commercially, to succeed in accomplishing the desired result. The Commissioner holds that the application of the Faure secondary battery to the propulsion of vehicles was an obvious use, and that the public are entitled to practise a given invention in all its obvious utilities when the patent has expired, and may not be lawfully debarred from the enjoyment of it by subsequent patents seeking to monopolise uses which, although special, are at the same time recognised by persons skilled in the art as pertaining to it.

INDIA RUBBER.—At a meeting of the india rubber goods manufacturers, which was held in New York on the 26th of February, there were present the representatives of all the rubber boot and shoe companies in the United States. It was resolved to advance the prices of rubber boots, shoes, and goods 10 per cent. Attempts are being made to organise a rubber trust. The price of raw rubber is very high.

SOUTH AMERICAN TRADE.—Pittsburg manufacturers are making some attempts to capture part of the South American trade. With this end in view an agent has been sent out by the Oliver & Roberts Wire Company, Park Brothers & Co., steel manufacturers, Macbeth & Co., gas manufacturers, and several smaller Pittsburg concerns, to establish a trade for their products in South America. He will spend six months in the principal cities along both coasts, and will, if possible, establish agencies, and ascertain in what line of manufactories there is an opportunity to get a foothold. It is believed that with their enormous plants, cheap fuel, and superior methods, the Pittsburg establishments will be able to sell goods as reasonably as the European firms who have the advantage of cheap labour.

SUGAR.—The appointment of a receiver for the American Sugar Refinery of San Francisco has again given Mr. Claus Spreckles the monopoly of the sugar business on the Pacific Coast. The first act of the Receiver was to close the establishment as soon as the sugar in the vats was worked off, and 500 men were discharged. Granulated has risen in consequence. In the East there is a light business in raw sugar owing to a lack of demand. Refined sugar is stronger. The report of the Kansas State Sugar Inspector gives a most encouraging outlook for the future of the sugar industry in that State.

LYON'S IMPROVEMENTS IN SLIDE VALVES.

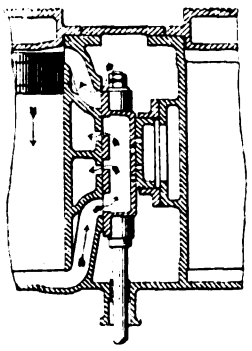

FIG. 1.

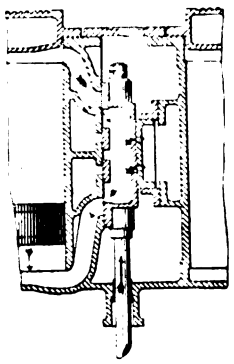

FIG. 2.

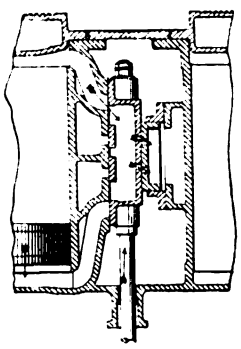

FIG. 3.

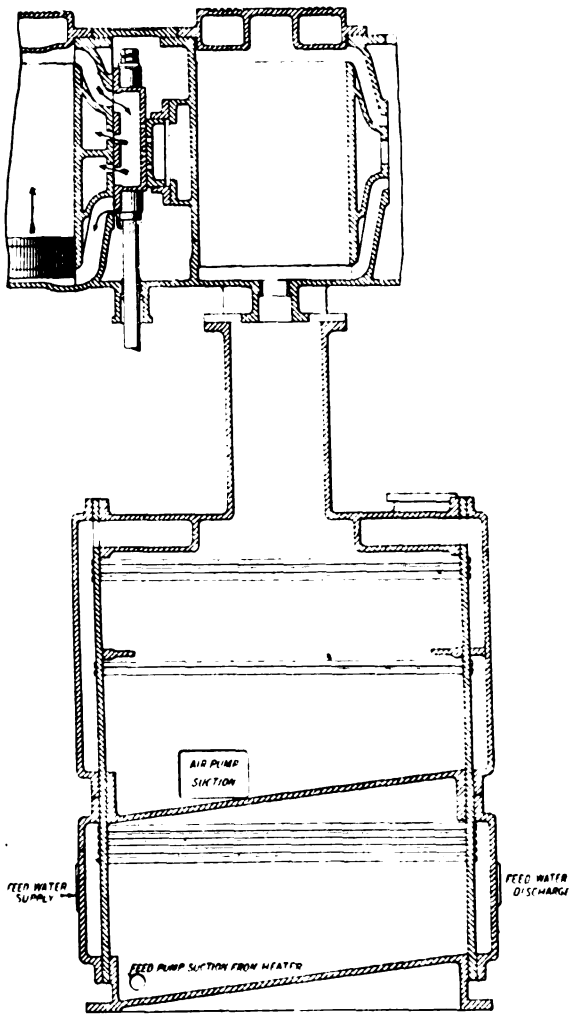

FIG. 4.

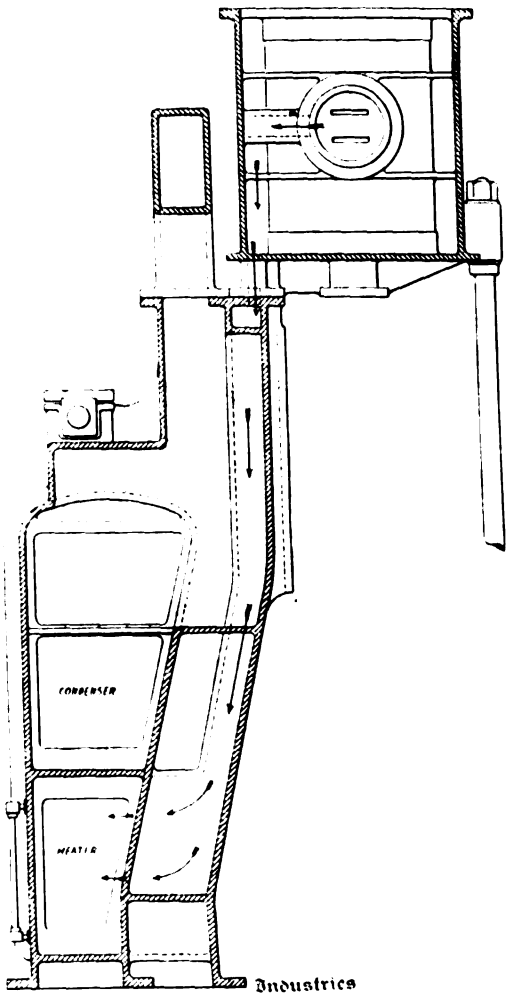

FIG. 5.

LYON'S IMPROVEMENTS IN SLIDE VALVES.

IN the illustrations above we show a new arrangement of slide valve which is designed for cushioning the low-pressure pistons in multi-cylinder engines and for heating the feed water, which has been patented by Mr. James Gourdon Lyon, a member of the firm of Gourlay Bros. & Co., Dundee. In the illustration, the apparatus is shown as applied to a small set of triple-expansion engines whose cylinders are 14in., 22½in., and 36in. in diameter by 27in. stroke. The lowest section of the condenser forms a heater through whose tubes the feed water passes on its way to the boiler. Some of the steam which is exhausted from the low-pressure cylinder is sent into the heater on its way to the condenser, and thus imparts some of its heat to the tubes through which the feed water circulates.

The slide valve is made of box form, and it has apertures in its face which make communication with the exhaust and cylinder ports, and apertures at its back opening and closing communication to the heater. The heater and condenser have separate communications to the low-pressure cylinder, and part of the exhaust steam is first passed to the heater and what remains in the cylinder to the condenser. In Figs. 1, 2, 3, and 4, the valve is shown in the effective positions it occupies during one revolution of the engine. In the position shown in Fig. 1 the piston of the low-pressure cylinder is at the commencement of its downward stroke; the valve is admitting boiler steam to the top of the piston and exhausting the steam below the cylinder to the condenser. In Fig. 2 the piston has nearly completed its downward stroke, and the valve is passing the steam from above the piston to below it, and to the feed water heater. Fig. 3 shows the piston at the point where the feed water heater is just shut off from the bottom end of the cylinder, but still in communication with the top end, and where the compression below the piston is just commencing. Fig. 4 shows the piston on the bottom centre, and the space above the piston in communication with the condenser. Fig. 5 shows a transverse view of condenser and passages. The advantages claimed by Mr. Lyon are that the cushioning of the low-pressure piston is very effective; that it saves otherwise wasted steam; that the ports, cylinder, and piston are warmed before steam is admitted from the chest, and that the feed water is heated on its way to the boiler.

COAL, IRON, AND COGNATE INDUSTRIES.

THE Board of Trade returns, which have now been issued for the second month in the year, must be regarded from a general point of view as being of a fairly satisfactory character. The figures relating to the industries under review bear witness to a large volume of business conducted at remunerative values. The total declared value of the imports for the month of February and for the two months of the present year show a decrease of £1,321,254 and £1,235,722 respectively as compared with the corresponding periods of 1889. The total declared value of the exports for the month was £21,084,228, and for the two months £42,670,980, being an increase of £2,413,876, or nearly 13 per cent., and £3,473,591, or about 8 per cent., respectively, as compared with the corresponding periods of 1889. The total quantity of iron and steel exported in February was 277,062 tons, valued at £2,392,042, as compared with 262,278 tons, valued at £1,962,958, in February, 1889, being an increase of 5½ per cent. in quantity and 22 per cent. in value. The enhanced value of materials is shown principally in the crude metal and in railroad iron. In the latter case the quantity exported showed an increase of 50 per cent. in quantity and 80 per cent. in value. We append our usual tabular statement:—

	Month of February.		Two Months.	
	1890.	1889.	1890.	1889.
Pig and puddled...	£214,096 ...	£122,086 ...	£460,798 ...	£275,776
Bar, angle, &c.....	120,070 ...	139,533 ...	257,230 ...	275,458
Railroad.....	556,241 ...	308,478 ...	1,094,923 ...	684,753
Cast and wrought	483,827 ...	388,203 ...	968,065 ...	787,172
Hoops, sheets, &c.	308,695 ...	297,901 ...	650,637 ...	625,442
Unwrought steel...	148,051 ...	111,024 ...	205,555 ...	217,866
Unwrought copper	229,406 ...	39,423 ...	394,524 ...	92,647
Coals.....	1,337,621 ...	957,928 ...	2,693,622 ...	2,017,611

The great increase in the exports of unwrought copper might have been expected, and is pretty equally distributed among the various markets. An increase of 39 per cent. in the value of the exports of coal is a gratifying feature of the returns.

When we turn from such a satisfactory retrospect of the export trade of the first two months of the current year to the home markets, it must be a matter of great disappointment to find the existence of a different state of affairs. The gambling in the Scotch markets which took place during the latter part of 1889 has induced a reaction, the full effect of which is now being felt throughout the country. We cannot profess much sympathy for the thousands of individuals—clerks, clergymen, shopkeepers, and commercial men—who, in helping to bring about this result, have found themselves mulcted in heavy "differences"; but it is unfortunate for the staple industries of the country that trade should be paralysed, and the tide of prosperity stemmed, as the result of a rash speculative mania, the collapse of which was inevitable. The result of the severe fall in the value of warrants has been to induce consumers and merchants to withhold their orders, and thus to bring manufacturers to easier terms. It is useless to disguise the fact that at the present moment producers are making substantial reductions in prices in order to obtain orders sufficient to keep their works going. The agitation amongst the colliers, with the possible prospect of a national strike, has also had its effect on the stability of trade. We do not consider a strike of any magnitude or of any longevity is probable, as neither employers nor employed can afford to lose what may turn out to be the few remaining weeks of remunerative prices, but if such should prove to be the case the detrimental effect of the agitation will not thereby be lessened. The supporters of optimism and pessemism have their respective theories as to the future course of trade, but the outlook has certainly become clouded during the current year.

THE FORTH BRIDGE.

On our two-page supplement this week we give a view of the completed Forth Bridge as now opened for traffic. The view is from the south-west, and the engraving is reproduced from a photograph by Messrs. Valentine & Sons, of Dundee. We have dealt so fully with the Forth Bridge in these columns and in our Special Number, that a detailed explanation of the engraving is not necessary.

Notices of Meetings.

NEXT WEEK.

Society of Arts.—Monday, March 24th, at 8 p.m. Lecture on "Some Considerations Concerning Colour and Colouring," by Professor A. H. Church, M.A., F.R.S. Tuesday, March 25th, at 8 p.m. "Engraving in Wood, Old and New," by W. J. Linton. Wednesday, March 26th, at 8 p.m. Sixteenth Ordinary Meeting. Lecture on "Carriage Building and Street Traffic in England and France," by S. N. Hooper. Saturday, March 29th, at 3 p.m. Lecture on "The Atmosphere," by Professor Vivian Lewes.

Institution of Electrical Engineers.—Thursday, March 27th, at 8 p.m. Paper on "Alternate *v.* Continual Currents in Relation to the Human Body," by H. Newman Lawrence and Arthur Harries, M.D.

Liverpool Engineering Society.—Wednesday, March 26th, at 8 p.m. Twelfth Ordinary Meeting.

Society of Architects.—Tuesday, March 25th, at 7.30 p.m. Paper on "The Influence of Material upon Design," by Mr. G. A. T. Middleton.

Royal Institution of Great Britain.—Friday, March 28th, at 9 p.m. Lecture on "Foam," by Lord Rayleigh. Saturday, March 29th, at 3 p.m. Lecture on "Electricity and Magnetism," by Lord Rayleigh.

Chemical Society.—Thursday, March 27th, at 4 p.m. Anniversary Meeting. Dinner at the Whitehall Rooms, 7 p.m.

Institution of Civil Engineers.—Monday, March 24th, at 7.40 p.m. Seventh General Meeting. Discussion on Mr. R. L. Weighton's paper on "The Institution's Rule for the Normal Indicated Horse-power of Marine Engines and Boilers." Paper on "The Structural Strength, &c., of Cargo Steamers of Different Types," by Mr. G. Bergström. Students' Meeting, Friday, March 21st, at 7.30 p.m. Paper on "Economy Trials of a Compound Mill Engine and Lancashire Boilers," by L. A. Legros, Student Inst.C.E. Ordinary Meeting, Tuesday, March 25th, at 8 p.m. Discussion on "Lough Erne Drainage." Paper on "Barry Dock and Railways," by John Robinson, M.Inst.C.E.

PRICES CURRENT, 19th March, 1890.

Quotations at per ton, unless otherwise specified.

ANGLES, PLATES, BARS.

Messrs. G. Bailey Toms & Co., London, quote as follows:—

	Com. £ s. d.		Best. £ s. d.	
Middlesbro' Bars	7 5 0	.....	7 15 0	f.o.t. wks.
„ Angles	7 0 0	.....	7 10 0	„
„ Plates	7 5 0	.....	7 15 0	„
Staffordshire Bars (cheaper makes)	8 17 6	.....	9 7 6	London.
„ Angles	8 17 6	.....	9 7 6	„
Crown Sheets	8 15 0	.....	9 5 0	„
„ Hoops	8 2 6	.....	8 12 6	„
"Siemens-Martin" Steel Boiler Plates			9 15 0	„
„ Ship and Girder			8 15 0	„

Market dull; demand quiet.

PIG IRON—BRAND "CARRON."

Present prices of "Carron" Pig Iron are as follow:—

	No. 1.	No. 3.
Prices, per ton ...	77/-	..... 66/6

F.O.B. Grangemouth or F.O.R. Carron Works, Stirlingshire.
Terms: Cash on 10th of Month, following delivery.

	Per Ton Extra.
Delivery at Leith or Granton	1/9
Do. at Broomielaw, Glasgow	2/-
Do. at London (over ship's side in Thames)	6/-
Do. at Liverpool (alongside export vessel)	—
Do. at do. (traders' dock)	—
Do. at Hull (on quay)	5/-

METALS.

Spelter: Ordinary	£23	0	0	to	£23	5	0
Copper: British Cakes and Ingots	54	0	0	„	55	0	0
„ Chili Bars, G.O.B.'s	47	2	6	„	47	10	0
„ Other sorts, G.M.B.'s (equal to Chili Bars)	47	2	6	„	47	10	0
„ Manufactured (strong)	62	0	0	„	.....		
Lead: Common Pig	13	12	6	„	13	15	0
„ English Sheet	14	2	6	„	14	5	0
Tin: Straits	90	5	0	„	90	10	0
„ Australian	90	10	0	„	90	17	6
„ English Ingots	95	0	0	„	.....		

Messrs. Carrick & Brockbank, Manchester, report as follows:—

Copper: No change of importance has taken place in copper during the past week. The market for Chili bars improved somewhat on the 12th, consequent on a better demand for refined copper for consumption. The reduction in the Bank rate on the 13th to 4 per cent. also tended to strengthen prices. A steadier feeling has since prevailed, and quotations to-day are £47 2s. 6d. to £47 10s. cash. Manufactured is still quoted £62 sheets and £65 bottoms, with a quiet market.

Tin continues inactive, with a very small business doing. Values are lower on the week, but steady at the moment.

Lead is also quiet, in sympathy with other metals, prices being slightly lower.

Spelter: The demand is quiet and prices are rather easier.

Zinc Sulphate	ton	7 10 0	—	.....

Messrs. S. W. Royse & Co., Manchester, report as follows:—

Chemicals: The effects of the coal strike are severely felt, especially by alkali manufacturers. Caustic soda is almost unobtainable on spot, stocks having been kept low for some time past. Soda ash also is very scarce. Bleaching powder has secured a good advance this week, though the pressure for the delivery of this article is not so great. In the sulphate of ammonia market there is no movement of any note. Carbolic acids continue depressed, and benzoles are lower. Oxalic acid is steady. Tartaric acid firmer. Yellow prussiate of potash easing.

FOREIGN TELEGRAPHIC ADVICES.

(From our own Correspondents.)

Paris, March 20.—*Iron.*—The strike of miners in England has greatly strengthened the tone of business here. Bars are firm at 160s.; joists, 164s. A similar effect has been produced in the markets of the provinces. In Haute-Marne business very active. Wire in strong demand. Wire nails largely bought at 216s. to 224s. a ton. In Ardennes markets firm. In Nord quiet, but improving in tone.

Metals.—Copper maintains its price at £52 Chili bars and £57 best selected, but there is hardly any business doing. Tin remains dull in spite of some improvement abroad: Banca, £99; Straits, £96. Lead is recovering a little. Paris £13 5s. Spelter has further receded. Silesian, £24, Havre. Demand light.

Berlin, March 20.—*Bourse.*—The market for industrial securities is somewhat weaker in consequence of apprehensions concerning the course entered upon by the German Emperor relatively to the labour question. Shares in iron manufacturing and colliery companies retain the improvement gained last week, thanks to the strike of English miners, but the tone of business is weak and hesitating.

Iron.—There is a growing demand for building iron; but on the whole the market is less favourably situate than it was a week ago. Buyers hesitate, and limit their dealings to present necessities. An uneasy feeling prevails relatively to the labour question. Good Silesian bars are quoted from 205s. to 210s. a ton. Other prices remain unaltered.

Metals.—Business in metals continues slack; only the most urgent needs of the moment are being covered by current transactions. Prices for Mansfeld refined copper remain firm at £59 to £60. English brands are still quoted at £56 to £57. Tin is very dull at £100 to £101 for Banca. The market for lead is quiet, but moderately firm: Claustthol refined, £15 10s. to £16. Spelter firm, at £25 15s. to £26 10s. for Silesian W. H. brand; ordinary, £25 to £25 10s.

Breslau, March 20.—*Coal.*—The tone of the coal market has become distinctly firmer since the declaration of the strike in England. Upper Silesian coal is making headway against English competition in some of the markets of North-East Germany. The advance reported last week is readily paid by consumers.

Iron.—The demand for pig iron continues brisk. Forge pig in second hands is quoted higher, 85s. to 90s. a ton. There is great activity in the market for finished iron and steel. Boiler plates are much sought after at from 250s. to 260s. For the local trade bars are quoted 220s. Founders report brisk business in machinery castings and in cast iron pillars for export.

Metals.—The market for zinc continues languid. Sellers of spelter are making small concessions in prices to induce buyers to operate. Zinc dust, which is but little inquired after, has receded in price from £19 10s. to £20 per ton to £17 10s. to £18. The prices of lead, in which there is a fairly active current of business, remain unchanged.

Düsseldorf, March 20.—*Coal.*—There is no diminution of activity in the market for coal. Prices remain unchanged. Merchants manifest a disposition to make harder terms with buyers. Large bodies of miners are withdrawing themselves from the Socialist party. This circumstance is favourable to the maintenance of peace in this district.

Iron.—There is a little more life in the market for pig iron. Consumers, having apparently convinced themselves that lower rates are not to be hoped for for some time to come, are disposed to deal more freely. Prices are firm all round. The market for finished iron and steel has not recovered from the loss of business reported last week, but prices exhibit no tendency to decline. Hoops are in brisk demand for home consumption. Wire is very dull.

Charleroi, March 20.—*Coal.*—The exceptional demand for coal on German account keeps the market buoyant. No business is done below the full official rates. The date for receiving tenders for 150,000 tons of coal for the State railways is fixed for the 3rd of April. This quantity is divided into seventy-five lots.

Iron.—A stronger tone in the market here has resulted from the colliers' strike in England. There is not much buying, however. Makers of finished iron say that present prices leave no margin for profit. The output of the blast furnaces is now less than it was a month ago.

Ghent, March 20.—*Flax and Yarns.*—The demand continues very brisk for home-grown flax of all sorts, and prices are steadily rising. There is not much doing in Russian produce. The quality is complained of. Yarns are actively dealt in at last week's prices.

Erratum.—In the description we gave in our last week's issue of semi-portable hauling engines, constructed by Messrs. John Wild & Co., Ld., engineers, Falcon Ironworks, Oldham, the cheeks of the drum were inadvertently stated to be "2in. thick"—"½in. thick" should be read instead of "2in. thick."

Liverpool Engineering Society.—The eleventh ordinary meeting of this Society was held on the 12th inst., the President, Mr. Henry H. West, M.Inst.C.E., being in the chair. After the usual routine business, Mr. Charles H. Yeaman gave a *résumé* of his paper, entitled "Notes on Central Station Electric Lighting," which was read before the Society on January 29th last, and a long and interesting discussion took place. Afterwards Mr. Yeaman replied to the various points raised during the discussion.

HOME INDUSTRIES.

LONDON 20th March, 1890.

THE MONEY MARKET.—The money market is easy and featureless, without any indication of immediate change. The position of our market is strong just now, and arrivals of gold from abroad continue to reinforce it. The demand for money is in moderate proportions, and the supply is equal to all needs, and rates are consequently easy. The stock markets are uncertain in tone, with a tendency towards dulness. The wages difficulty in the coal trade acts as a damper on home securities, the quotations of the stocks of the mineral-carrying lines declining in view of the restriction of the coal output. Foreign securities have been adversely affected by the announcement of Prince Bismarck's resignation, the bonds of the States of South-Eastern Europe showing themselves most sensitive to this influence. American railway shares are rather uncertain in tone, with a disposition to move towards better prices. Canadian lines continue to show good traffic returns. The market for miscellaneous securities is very dead, and the little spurt of fresh life which lately showed itself in the mining department has exhausted itself.

COMPANIES.—The following companies have been registered since our last report:—Northfleet Portland Cement Co., Ld., with a capital of £100,000; Macmahon's Patent Electric Cheque System, Ld., with a capital of £30,000; Rivers Purification Co., Ld., with a capital of £100,000; The British Copal Refining and Varnish Manufacturing Co., with a capital of £100,000; Inesperada Gold Mining Co., Ld., with a capital of £60,000, to carry on mining operations in Chili; Gippsland Proprietary Co., Ld., with a capital of £200,000, to acquire certain mineral leases in Victoria, Australia; St. Helens Smelting and Sulphate of Copper Co., Ld., with a capital of £60,000; Aldous, Son, & Co., Ld., with a capital of £8,000, to carry on the business of engineers; Pontianak Diamond Syndicate, Ld., with a capital of £20,000, to carry on mining operations in Borneo; Brewery Assets Corporation, Ld., with a capital of £705,000; White River, Colorado, Coal Syndicate, Ld., with a capital of £12,480; Phosphorus Co., Ld., with a capital of £150,000; North African Exploration Syndicate, Ld., with a capital of £5,000; Key's Electric Co., Ld., with a capital of £15,600, to carry on the business of electrical engineers; The Sulphur Co, Ld., with a capital of £10,000; British Paper Co., Ld., with a capital of £3,000; Latha, Ld., with a capital of £10,000, to acquire a patent for making corks; McMillan's Patent, Ld., with a capital of £1,000, to acquire certain patents; South Barracas (Buenos Ayres) Gas and Coke Co., Ld., with a capital of £50,000; Kilhivan Mines, Ld., with a capital of £120,000; Krantner's Bluman Brewery, Ld., with a capital of £75,000; Mount Osmond Silver Lead Mining Co., Ld., with a capital of £100,000; Patent Weldless Steel Chain Co., Ld., with a capital of £12,000; Balaghat Mysore Gold Mines, Ld., with a capital of £150,000; D'Eresby and Gwydyr Mines, Ld., with a capital of £20,000; Central Silver Mining Co., Ld., with a capital of £25,000, to acquire mines in Peru; Ashton-under-Lyne, Oldham, and Hyde Tramways, Ld., with a capital of £75,000; Durham Paper Pulp, Ld., with a capital of £20,000; Patents Mining and Financial Trust, Ld., to acquire any inventions, &c., relating to chemical, mechanical, or other matters; The Liberian Government Concessions and Exploration Co., Ld., with a capital of £110,000.

WORKMEN'S EXHIBITION.—There is going to be opened, on the 9th of April, at the Central Hall, Holborn, under the auspices of the Working Men's Club and Institute Union, Limited, an Exhibition of work in various trades, including engineering and machinery and metals, building, leather, textiles, scientific instruments, and so on. One section is devoted to workmen and apprentices, another to amateur work, and a third to feminine trades. The exhibits will be mainly from clubs affiliated to the Union, and entries will have to be made by Monday next, the 24th inst. The office is at 150, Holborn, E.C. Several of the City Companies are contributing to the enterprise, and about 700 exhibits are expected.

INSTITUTION OF NAVAL ARCHITECTS.—The following are a list of the papers to be read before the above Institution on the 26th, 27th, and 28th inst.:—"Notes on Recent Naval Manœuvres," by W. H. White, Esq., F.R.S., Director of Naval Construction, Vice-President; "The Maritime Conference," by Rear-Admiral P. H. Colomb, R.N.; "On Leak Stopping in Steel Ships," by Captain C. C. Penrose FitzGerald, R.N.; "Strength of Ships, with Special Reference to Distribution of Shearing Stress over Transverse Section," by Professor P. Jenkins; "Steatite as a Pigment for Anti-corrosive Paints," by Frank C. Goodall, Esq.; "On the Evaporative Efficiency in Boilers," by C. E. Stromeyer, Esq.; "On the Application of a System of Combined Steam and Hydraulic Machinery to the Loading, Discharging, and Steering of Steamships," by A. Betts Brown, Esq., F.R.S.E.; "The Revolving Engine Applied on Board Ship," by Arthur Rigg, Esq.; "On the Variation of the Stresses on Vessels at Sea due to Wave Motion," by T. C. Read, Esq.; "Spontaneous Combustion in Coal Ships," by Professor Vivian Lewes, F.C.S.; "On the Screw Propeller," by James Howden, Esq.; and "Experiments with Lifeboat Models," by J. Corbett, Esq.

THE "EIFEL AUTOMATIC AËRATOR."—We recently inspected the working of an apparatus for aërating mineral waters by means of natural carbonic acid gas. This is known as the Eifel Automatic Aërator, and consists of a small machine in which is a mixer and pump, and to which is attached a swing cradle of the usual type for holding the bottle during charging. The oscillation of the cradle is obtained by a lever, one stroke of which turns the bottle upwards for charging, and at the same time forces the water into it. The reverse stroke draws into the pump the exact quantity of water required to fill a bottle, so that, given a tank or other source of water supply, the machine is a self-contained aërator and bottler. The gas is collected at the Eifel springs on the Rhine, and is evolved from the surface of the wells after passing through about 250ft. of water. It is then compressed into steel tubes until a pressure of 900lb. is obtained, after which the outlet of the tube is closed by a wheel valve, and a cap is screwed over the latter to protect it in transit. The tubes are tested by the German officials to 3,000lb. prior to being used for storage. When coupled to the machine the wheel valve is slightly opened to admit sufficient gas to set up within the apparatus the necessary pressure, and the expansion of the gas within the mixing chamber causes a loss of heat by which the water is cooled. The aëration at 100lb. pressure was superior to that usually obtained at higher pressures, and the time occupied in bottling was very small. The makers state that 30 dozens of full-sized bottles can be filled and the water aërated in an hour, and this statement would appear to be an accurate one. The machine stands in a very small space, and brings within the reach of almost everyone an easy method of producing aërated waters. It is being worked in this country by the Eifel Automatic Aëration Company, 112, Strand, London.

ROYAL INSTITUTION.—The discourse to be given by Lord Rayleigh, on Friday evening, March 28th, will be on "Foam."

COPPER.—Messrs. James Lewis & Son report that from £47 on the 3rd inst. good merchantable copper declined to £46 10s. on the 6th. Scarcity of available warrants and a moderate demand for cash caused an advance from this point to £47 15s. on the 13th, but 10s. of this improvement was lost on the 14th. The closing value is £47 7s. 6d. cash and £47 13s. 9d. three months' prompt, buyers. The warrants for the 4,000 tons of good merchantable copper sold by the French holders early in the year have now been nearly all absorbed by consumers, and, as the demand exceeds the arrivals, there seems great probability that the market will again advance to the level at which the French bankers will be willing to sell a further portion of their stock. The quotations on Monday were:—Chile bars and good merchantable copper, £47 7s. 6d. cash, and £47 13s. 9d. three months' prompt, buyers. English, best selected, £54 to £55; and tough cake, £52 10s. to £53 10s. per ton. American matte 10s., and good ore 9s. 9d. to 10s. per unit.

MANCHESTER, 20th March, 1890.

THE COAL TRADE.—The greater part of the miners in Lancashire have now struck work, although in some special cases the advanced terms have been given and the men continue at work. There are a number of indications that the advanced rates will be granted by a large number of colliery proprietors before long. In the meantime those who have any coal to sell are getting big prices. In one instance a cotton spinning company has a contract running for 2,500 tons at 8s. 2d. per ton delivery, which it is unable to get, and has 250 tons of an inferior quality offered as a favour at 18s. 6d. per ton. This is a sample of the existing state of things throughout, and observations show that the pit-bank accumulations will be cleared out at a good price if the strike continues. In some places works are already stopped, the scarcity being especially felt by the ironworks of the district. A few days' continuance of the strike will result in a general stoppage, the supply of coal having for some time been so little above the demand that users have been quite unable to accumulate stocks. The joint conference to be held to-day is looked forward to with much hope, and it is expected a compromise will then be arrived at. The whole trouble demonstrates the necessity for a Wages Board such as exists in Cleveland and South Staffordshire.

EMPLOYMENT IN THE ENGINEERING TRADES.—Recent reports published by the Amalgamated Society of Engineers and the Steam Engine Makers' Society show that the percentage of unemployed members remains remarkably low, being respectively 1 and ½ of 1 per cent. There are a few disputes as to wages in this district, but they do not generally affect the result stated.

MEASURING AND FOLDING MACHINE.—A simple machine is being introduced in this market, the object of which is to enable the folding of piece goods to be effected without creasing them as is the case at present. As ordinarily wound, the inner layers of the fabric are very badly creased, but by an ingenious contrivance the drag on the cloth is reduced as the bundle is formed, and the creasing is entirely obviated. This is a source of loss to merchants and drapers, and the new style of wrapping is likely to be much appreciated by the former. The machine, which is made by Mr. C. Bell, of Richard Street, Bradford, is provided with a measuring drum and indicator dial, by which the length of a piece can be ascertained and checked.

THE LINEN AND JUTE TRADES.—One topic—that concerning the coal strike—overshadows all others. The effects of the sudden cessation in the supply of fuel are felt in every branch of Manchester trade, directly or indirectly. The distributing houses are affected, because their customers, the retailers, who are of course in close touch with the public, the first sufferers, find sales diminishing. Nevertheless the linen branches have had a fair share of what has been going, and in Scotch makes a satisfactory amount of business is doing, although a little more activity on the part of buyers would by no means unduly tax the productive capacity of the mills. Though not a linen manufacturer's case, the action of Messrs. Barlow & Jones against a local firm for trade mark infringement has been watched with interest by those concerned in the linen industry, and the judgment of Mr. Justice Chitty has been generally received with satisfaction. There is a fair inquiry for hucks and crashes, but drills are not in such request as could be wished, largely owing to the dulness which prevails in the South American and other foreign markets. Damasks of Dunfermline make and German specialties in silk and linen mixed goods go off well, and the last named articles command high prices in comparison with similar class fabrics of British manufacture.

GLASGOW, 20th March, 1890.

THE NEW TUBE COMPANY.—The prospectus has now been issued of the company to whose formation reference was made in these columns a fortnight ago. The company has been formed for the purpose of taking over and amalgamating the businesses at present carried on by Andrew & James Stewart, Ld., the British Tube Company, Coatbridge, and the Clydesdale Iron and Steel Company, Mossend. The capital of the company is £700,000, divided into £250,000 of 6 per cent. cumulative preference stock in shares of £10 each, and £450,000, in ordinary shares of £10 each, 16,000 preference shares and 30,000 ordinary shares are offered for subscription. The leading firm in this combination, Messrs. Andrew & James Stewart, was established in 1861, and the Clydesdale Company in 1870. The board of directors of the new company consists of the following: Andrew Stewart, John Wotherspoon, Sir William Arrol, James L. Mitchell, Dugald McCorkindale, Andrew Bain, and John Graham Stewart. A sum of £650,000 is to be paid for the properties, partly in shares and partly in cash. The net profit of the concerns for the past seven and a half years is stated at £66,000.

RAILWAY RATES INQUIRY.—The Railway Rates Commissioners began their sittings in Scotland at the Royal Hotel, in Edinburgh, on Monday, the 17th inst. The Commissioners were Lord Balfour of Burleigh and Mr. Courtenay Boyle, C.B. A formidable array of legal talent represented respectively the Scotch railway companies and the traders objecting to the proposed classification. It is estimated that this inquiry is being conducted at an expense of £3,000 per day, and since it is expected that twenty days will be occupied in the hearing of evidence on the Scotch cases, the cost to the traders and to the public will be on this estimate about £60,000. The first witness examined was Mr. John Walker, well known as the General Manager of the North British Railway Company. Mr. Walker's examination lasted all day on Monday, and was resumed on Tuesday morning. Those who had the privilege of hearing it will remember it as among the ablest performances of a witness under examination and cross-examination. In reference to the fixation of maxima rates, Mr. Walker insisted that the fluctuations in the working expenses due to alterations in the prices of iron and other materials, and in the cost of labour, rendered it necessary for the companies to possess powers to charge on occasion higher rates than might normally be necessary. He maintained that both the classification and the rates were fairly fixed, and that the companies had no intention of charging the maximum rate, pointing out that they had not hitherto taken full advantage of the powers invested in them by various Acts of Parliament.

ENGINEERING.—Messrs. Neilson & Co., Hydepark Locomotive Works, Springburn, are supplying some fine engines of the "Fairlie" type for the Mexican Railway. These engines are specially constructed for travelling on steep grades, no less than 14 miles on which constant grades of 1 in 25 have to be traversed in combination with curves of 330ft. radius.

LABOUR.—A number of non-Union men were engaged by Messrs. Allan in loading the "Canadian." As the work proceeded slowly, Messrs. Allan had bills posted offering steady employment at 30s. per week for day work, and 35s. for night work.

EXPERIMENTS WITH A NEW EXPLOSIVE.—Under the auspices of the agents in Scotland, Messrs. A. Baird & Son, Glasgow Mr. Dobbie, from the Flanders Explosive Company, has recently carried out several successful experiments in a number of the collieries in Hamilton, with the new explosive, called "Securite."

PIG IRON.—A steady firm tone has characterised the pig iron market this week, while the complex nature of the consequences of the great labour troubles in England had a discouraging effect upon speculators. The evident impossibility of producing pig iron cheap imparts confidence to buyers and holders. Prices were consequently well supported, a large business being done whenever sellers showed a willingness to accept 50s. 3d. cash. There are not lacking evidences of good work yet to be done in most departments of the iron trade, much of which has been delayed by dear money and by the high prices which were asked some weeks ago.—Messrs. Wm. Dixon, Limited, of the Govan Ironworks, Glasgow, have decided to take up the manufacture of briquettes on an extensive scale, and have ordered a complete plant capable of turning out 100 tons per diem, from Messrs. Yeadon & Co., Leeds.

(From our own Correspondents.)

LIVERPOOL, 19th March, 1890.

Important Scheme of Dock Improvement.—At the last meeting of the Mersey Dock and Harbour Board, an important scheme for the improvement of the north dock was considered, which will involve an estimated expenditure of £1,000,000. The leading features of the scheme are as follows: (1) The deepening of the southern part of the Canada basin to 14ft. below old dock sill and the provision of sluices to maintain that depth; the deepening of the Canada lock to 12ft. below O.D.S., and the lengthening of the lock to 600ft., at an estimated cost of £68,000; (2) the alteration of the Canada dock by removing the present south passage and the construction of a new 80ft. passage to the Huskisson dock, with sill 9ft. below O.D.S.; deepening the dock, straightening the quays, and constructing new shed at a cost of £165,000; (3) constructing a new dock 300ft. wide at the southern end of the Canada dock, with new sheds, at a cost of £237,000, or a total of £470,000; (4) the provision of pumping machinery for raising the water level in the Huskisson and Canada dock at a cost of £50,000; the construction of a graving dock at a cost of £65,000; and the construction of a half-tide dock on the site of the London basin, with deep water entrance to the river, at an estimated cost of £415,000. It was decided to carry out the first portion of the scheme, involving an outlay of £470,000.

The Mersey Railway Company.—In the directors' report for the half-year ending December 31st, it is stated that the total receipts amounted to £28,175, as compared with £25 598 for the corresponding period last year; the working expenses were £23,498, or at the rate of 83·40 per cent., as against 90·48 per cent. last year. The number of passengers conveyed was 4,268,288, as against 3,786,480 last year, exclusive of season tickets, which numbered 1,850.

The Strike of the Dock Labourers.—This unfortunate strike still continues, and the men refuse arbitration; the shipowners receive fresh drafts of men each day, and a large number are now employed, many of whom will no doubt be retained by their employers after the strike is over. It has been considered advisable to obtain the assistance of the military and additional police to preserve peace and protect the workers. An attempt has been made to induce the carters and others to join in the strike, but their union has passed resolutions against such action being taken. There are signs of disagreement amongst the leaders of the strike, which may soon lead to a collapse.

SHEFFIELD, 19th March, 1890.

The Coal Trade.—Although the coal strike is but three days old there are already many thousands of men engaged in other industrial occupations thrown out of employment. Several manufactories had to suspend operations on Monday through want of coal, and it is estimated that by the week end there will be no less than 40,000 men idle for want of fuel, as, with the exception of the large Brightside firms, who own collieries, very few can continue working more than a few days. Messrs. John Brown & Co., Limited, of the Atlas Works, have stocked something like 30,000 tons of coal, and Messrs. "Cammells," who are extensive colliery proprietors, have 60,000 tons. This stock, however vast it may appear, will only serve a few weeks. The Sheffield Gas Light Company have also secured a stock of 12,000 tons.

Engineering.—Employment is very good in the engineering trades, where the men are agitating for an advance of 2s. per week, making the standard rate of pay 36s., which the best men have had for some time. Blacksmiths are rather scarce here now, and can earn from 10s. to £1 per day when on piece work. The annual report of Messrs. "Cammels" is very satisfactory. The balance-sheet for the year 1889 shows the profits to have been £171,081 7s. 10d. Other manufacturing concerns also show fair profits on last year's working, and, granted a fair year's work, it is highly probable that 1890 will give equally as good returns.

The Sheffield Society of Engineers.—An elaborate paper, entitled, "The Indicator and its Practical Working, with a Description of the Tabor Indicator," was read before this Society, on the 15th inst., by Mr. A. G. Brown, M.A.S.M.E. The author, in commencing, referred to the office and scope of the indicator, and showed that its use was not restricted to steam engines. He then gave a history of the indicator, and a sketch of the leading instruments that have been used. Various arrangements for giving motion to the indicator barrel were shown, and the proper method for taking diagrams described. A number of characteristic diagrams were referred to in the paper, and also very full instructions were given by the author, as the result of his extensive experience, with the view of showing the valuable data which may be obtained from a carefully taken indicator diagram.

LEICESTER, March 19th, 1890.

Wool Spinning and Yarn Trades.—The conditions of the local wool market do not show any great change. There is an uneasiness prevalent, prices are firm on the whole, but tendencies in some quarters to soften. Stocks are generally light, and holders do not press sales, whilst buyers abstain from operating beyond pressing wants. This attitude causes much uncertainty in trade. English lambswools are very scarce and eagerly bought up. The following prices are prevailing:—Deep stapled lustres, half hog and ewes, 28s. to 29s. per tod; superior hogs, 29s. 6d. to 30s. 6d.; Shropshires, average quality, 30s. to 31s.; superior, 31s. to 32s. per tod. Spinners are moderately busy just now, and are extensively engaged in sampling. Placing new contracts is difficult in the face of the state of the wool market, and spinners decline offers at old rates. The yarn market is rather quiet. Cashmeres have declined in price.

SWANSEA, 19th March, 1890.

Tinplates.—The decision to stop work in the tinplate mills for one week has been adhered to by a much larger number of firms than was at first anticipated, and a reduction of stock of 200,000 boxes has been effected. This is regarded as a further proof of the very unfavourable conditions under which of late work has been carried on. Mr. J. R. Turnock, whose experience of the trade, both as manufacturer and in its commercial aspect, is well known, regards the present condition of affairs as entirely due to the incessant erection of new mills and the extensions that are going on in old works. The "survival of the fittest" would be his remedy. Whatever may be thought on this point Mr. Turnock strikes a pleasant note when he refers to the question of American Protection, which, to the minds of many people, seems to hang over the trade like a sword of Damocles. He thinks it would be a long time before any effect whatever would be felt in Wales from such a policy, and, apart from considerations of the advantages derived from actual possession of the trade, the canning industry of the States would be inevitably and irretrievably ruined, because other countries would have such an immense advantage over them "while the little game lasted that they would never be driven to earth again."

Refuges in Coal Mines.—The recent explosions at the Llanerch and Morfa Collieries, which have been attended by such a disastrous loss of life, have called attention to schemes by which men imprisoned in the workings might be kept safe from the effects of the after-damp until assistance could reach them. A plan of this kind has already been adopted at Tylerstown, where the refuges are constructed of good air-tight masonry or of steel, and are supplied with fresh air from above ground by means of adequate pipes, an outlet valve being provided. Every collier knows the position of the nearest refuge, and in the event of an explosion an immediate rush is made for it.

CARDIFF, 19th March, 1890.

Coal and Coke.—There is still a spirited demand for coal, and the labour difficulties in the northern centres have had the natural effect of keeping the tone firm. Prices for best quality are 16s. to 16s. 9d.; second, 15s. 3d. to 15s. 9d.; and third, 14s. 6d. to 15s. f.o.b. Cardiff or Barry. Buyers, who have held back their orders in the hope of lower prices, are now coming into the market freely, and colliery owners find it impossible to load the steamers tendered to them in the limited time stipulated in the charter parties, in consequence of which steamers have now to wait four or five days for cargoes which formerly were loaded in 36 to 48 hours, and, as freights in all directions are low, shipowners are feeling the position very acutely. Small coal finds a ready sale, and the demand for coke is steady. A large quantity of coke has been sold for shipment to Bilbao, where North-country coke has until now had almost a monopoly.

Iron and Steel.—The pig iron warrant market has depressed legitimate business, but now that the violent fluctuations caused by outside speculation seem to have ceased, there is every prospect of a steady business. Steel rails are weaker, and the inquiry has fallen off considerably. Steel bars for tinplate making are quoted at £7 5s. to £7 15s., but lower prices have been accepted. Tinplates do not seem to have improved much, notwithstanding the enforced stoppage of the majority of the works. Iron ore is quiet, but prices in Spain are very firm, the demand evidently being far in excess of the supply.

BARROW-IN-FURNESS, 19th March, 1890.

Hematite Pig Iron.—The make of hematite pig iron has already been reduced by the blowing out of a furnace at Millom and another at the Lowther Works. Three other furnaces will be blown out before the close of the month at the Carnforth, the Harrington, and the Maryport Works, and there is reason to believe that other furnaces will soon be damped down, not perhaps so much with the direct intention of reducing the output as because of the paucity of fuel. Already the effects of the coal strike are being felt in the district, and in a few days makers of iron will either have to damp down furnaces or put them on slack blast. Thus the output will, by force of circumstances, soon be reduced to a marked extent, and in the meantime, as makers are quoting from 70s. per ton upwards for mixed numbers of Bessemer iron, while hematite warrants are changing hands at 64s. 6d. per ton, the chief trade being done is in the latter, with the result that stocks are being gradually reduced. This week they show a decrease of 2,455 tons, and they now stand 8,976 tons less than they did in the beginning of the year. The aggregate of the warrant stocks now represents 372,680 tons. Prices of pig iron are expected to advance as a result of the present crisis in the coal trade and the enforced restriction in the output of pig iron.

Steel.—A quiet tone prevails in the steel trade, and orders are not offering on a large scale for any of the classes of the district's product. Makers are so well employed that they are not troubling themselves about the depression in prices, but are waiting until the present crisis is over before again pressing business. Heavy rails are down at £6 per ton, and merchants in some cases are quoting below this figure. Steel shipbuilding material is in quiet demand, with plates at £8 and angles at £7 10s. The tinplate bar trade is quieter in tone.

MIDDLESBROUGH, 19th March, 1890.

Pig Iron.—The pig iron market seems to have quite recovered its tone. Yesterday the market opened at 51s. 3d., but soon advanced to 52s. 3d., some sellers asking as much as 52s. 6d. per ton. For April-June delivery 53s. is offered, but none are inclined to accept. Makers are still out of the market, and are more than ever determined to hold on, as they consider prices are bound to rise in the immediate future. Warrants are thus very much run upon for shipments, and the warrant stores are being gradually depleted. Cleveland warrants are 52s. 2d. cash sellers and 52s. buyers. The stock in Connal's store on Monday, the 17th inst., amounted to 166,752 tons, as against 171,914 tons a week ago, showing a decrease over to the week of 5,162 tons. In hematite East Coast brands are quoted at 75s. per ton for Nos. 1, 2, and 3 makers' iron.

Manufactured Iron and Steel.—These are slightly better, if anything, but prices remain much the same. Iron ship plates, £7; angles, £6 15s.; common bars, £7 per ton, less 2½ per cent. on trucks at works. Steel ship plates, £8 5s.; angles, £8 2s. 6d.; rails, £6 12s. 6d. (heavy section) per ton free on trucks at works. Inquiries in both are more frequent, and meantime the works are busy enough on old orders.

Coals and Coke.—Coal is easier in all kinds, except coking coal, which is as firm as ever. Coke also is strong. If the miners are settled with the prospect is likely to be in the direction of easier prices still.

Engineers' Strike.—The engineers' demand for one hour's less labour in the week by stopping work at twelve noon instead of one p.m. on Saturdays was considered as good as settled, many firms having conceded it at once. The masters met yesterday, however, and decided not to grant the request of the engineers, whereupon the men have struck work to-day in obedience to orders from their union. Only Westgarth, English, & Co., marine engineers, are affected at Middlesbrough, and they are quite willing to concede the hour.

NEWCASTLE, 19th March, 1890.

The Engineers' Strike.—On Monday the whole of the operative engineers in the mid-Tyne and Newcastle districts came out on strike for what is called the "12 o'clock Saturday." The action of the Newcastle men with regard to this matter is somewhat singular, as less than a week ago they were almost unanimous in the acceptance of the masters' alternative offer, of a second shilling per week addition to the wages rate, with the option of ceasing work at noon on Saturdays, instead of at one o'clock, in shops where they were willing to work up the hour during the week. On Saturday, however, they reversed their vote of the previous Wednesday, because a majority of the men at the other centres had decided to reject the masters' offer, and to come out on strike for the "hour." This action greatly complicates the situation, as the employers now believe that the Tyne men are going against their conviction of what is right merely out of a desire to be at one with their fellows in other districts. They maintain, indeed, that by the first vote taken, their offer was accepted by the men to whom it was addressed—namely, those employed on the Tyne and Wear, and that is literally the fact if the voting on those two rivers only is taken into account, the figures being: For employers' offer, 4,480; against the offer, 3,917. The engineers' committee, however, insisted on combining Stockton and other places with Sunderland and Newcastle, and in this way secured a majority of the aggregate vote against the offer. The Mayor of Newcastle has offered to mediate, and it is considered probable that his mediation may lead to satisfactory results.

BELFAST, 19th March, 1890.

Shipbuilding.—It is stated that Messrs. Harland & Wolff, Ld., and Messrs. Workman, Clark, & Co., Ld., shipbuilders, have rented about 30 acres of the newly made ground on the County Down side of the river for the erection of engineering and boiler making works. The ground is in every way suitable, and is close to the new Alexandra Graving Dock and the 100 tons crane. The new White Star Liner "Majestic," which has been waiting to open the spring passenger traffic, will leave this port on the 22nd inst., after adjusting compasses.

Light Railway.—The scheme for promoting the light railway from the important fishing station of Airdglass to Downpatrick has now taken definite form, the Grand Jury of the Co. Down having voted £17,000 as their share of the undertaking. It will be about eight miles in length, and will cost about £6,500 per mile. It is expected to very largely develop the fishing industry, as before there was no quick communication with Belfast, the nearest export town.

Advertisements intended for insertion in the current week's issue should reach our London Offices not later than first mail delivery on Thursday morning. Scale of charges for displayed advertisements on cover and inside pages will be forwarded on application. Orders for single advertisements must be accompanied by payment in order to insure insertion, the charge for which is 2s. 6d. for the first four lines or under, and 8d. for each additional line. Situation advertisements (Vacant or Wanted) 1s. for two lines or under, and 6d. for each additional line—which averages eight words. While all practical regularity in the insertion of serial advertisements will be observed, it can only be absolutely guaranteed in the case of those ordered to appear weekly.

As we go to press early with certain of our advertisement pages, all Alterations to Standing Advertisements should reach the Publisher not later than 2 o'clock on Wednesday afternoon in each week.

All accounts are payable to GEO. CAWLEY, *358, Strand, London, W.C. Cheques should be crossed Manchester and Liverpool District Banking Co., Limited, 75, Cornhill, London, E.C. Post Office Orders should be made payable at the Post Office, 369, Strand, London, W.C.*

FRIDAY, 21ST MARCH, 1890.

THE NAVY ESTIMATES.

THE Navy Estimates for the year 1890-91, which have been issued along with an explanatory statement by the First Lord of the Admiralty, show that the sum voted in the financial year 1889-90 for the requirements of the Navy was £13,685,400, while for the year 1890-91 the amount to be asked is £13,786,000, being an increase of over £100,000. The largest addition comes under the head of shipbuilding material, and reaches £194,000. Wages are larger by £89,868, victualling and clothing by £42,100, and the *personnel* of shipbuilding by £35,556. On the other hand, there are decreases of £264,300 for contract work, of £5,200 for pensions and gratuities, and of £3,900 for reserved and retired pay. The total amount to be spent on construction, without armaments, in the coming year is estimated at £6,551,031, exclusive of the Australasian squadron. Of this amount £3,595,930, which is to be expended upon the vessels constructing by contract, is to be defrayed from the funds provided for by the Naval Defence Act of last year. The remainder will be paid out of the unexpended balances of 1889-1890, and by advances under the provisions of the Naval Defence Act. The scope of this Act does not seem to be clearly understood by the public, and therefore it may be explained that the twenty-one and a half million pounds with which it deals is not altogether extra expenditure. While the Act gives control over this amount, eleven and a half millions are voted from year to year as part of the annual provision for the Navy, while the remaining ten millions are charged upon the Consolidated Fund and are to be spread over a period of five years. If, however, the sums which are set aside for any year are not fully spent in that year the unexpended balances are to be disposed of by the Admiralty in such a manner that the total sum expended over the whole term shall suffer no reduction. Doubts are now, however, raised by the First Lord whether it will be possible to carry out the whole of the programme laid down in the Act; for he points out that during the financial year 1889-90 the extraordinary activity displayed in shipbuilding and other industries for the mercantile marine has caused a remarkable rise in the price of the materials employed in shipbuilding and of labour on contract-built ships. In the Naval Defence Act the estimates of the cost of work to be done were so framed as to allow a margin for a rise in prices and for other contingencies. This margin has, in many of the contracts made for hulls and machinery, been more than absorbed in consequence of the inflation of prices during the past year. There is at present a tendency to a fall in prices, but of course the amount of work which can be carried out with the money mentioned in the Bill will to a considerable extent depend on the prices prevailing during the next three years. The Admiralty are not, therefore, in a position to say whether during the next three years further sums may not be required to satisfactorily carry out the work of completing and thoroughly equipping the 70 ships included in the programme of the Naval Defence Act. The First Lord promises that, so soon as information is obtained to justify an authoritative statement on the subject, a full communication will be made to Parliament, but in the meantime the contracts made and the liabilities incurred will be kept well within the authorised maximum. We may be pretty certain from the start which has been made that we will have a demand for a considerable addition to the sum mentioned in the Act. With regard to the progress which has been made, the Act arranged that altogether 70 vessels should be built, 38 of which are to be undertaken in the dockyards, and 32 are to be built by contract. Of the former 21 have already been commenced, seven more will be commenced in 1890-91, and only ten will be left to commence after March, 1891. The ten thus left till after next year are five second-class cruisers and five torpedo gunboats. Of the 32 vessels that have to be built by contract under the Naval Defence Act, 26 were ordered before the close of 1889. The remaining six vessels are torpedo gunboats, which admit of being rapidly constructed, and which have been held over for the present. These 26 vessels include four battleships of the first class, five protected cruisers of the first class, and 17 protected cruisers of the second class. It was decided, after careful consideration, to give to the dockyard-built ships of each type a sensible start upon the contract-built ships of a similar type, in order that all details of fitting and equipment might be thoroughly worked out in the dockyards by naval and professional officers, and thus be available for guidance in the construction of the contract ships. These have been entrusted to eleven of the leading shipbuilding firms in the country, nearly all of them having had previous experience of warship construction. The work has been widely distributed. Eight of the vessels are building on the Tyne, eight on the Clyde, four on the Thames, three at Barrow, two at Hull, and one on the Mersey. The whole of the thirty-two vessels to be built by contract have thus been placed, except six torpedo gunboats, which have been kept back purposely pending the conclusion of the steam trials now going on. The designs of the new vessels were described in the statement of last year, and in Mr. White's paper which he read before the Institution of Naval Architects, so that we need not enter into them here; but it may be mentioned that advantage has been taken of the experience gained in the naval manœuvres of last year to improve some details. The most important of these had reference to coal tranport and ventilation of engine rooms beneath protective decks, and the suggestions which were made were embodied in the designs of the ships which are being built under the provisions of the Naval Defence Act. The First Lord states that the details of dockyard administration are carefully scrutinised, and the various charges are kept as low as is consistent with efficiency, and seldom are the estimates for building or repairs exceeded. The cost of building ships in the dockyards is steadily diminishing, though it is not yet so low as that of some of the ships procured by contract, after allowing a reasonable amount for incidental charges. We can never expect that cost to be so low as in private yards; but, as we have often pointed out, if "red tape" were minimised, and improved methods of work introduced, there are no reasons why the cost in the two cases should not approximate very closely, and we trust that the improvement which has taken place will be continued. Attention is now being directed to the administration and business of the foreign naval yards, with a view of improving their efficiency and

Digitized by Google

economising their expenditure, although the great distances from England makes this a difficult and slow process. The improvement which has taken place in the dockyards has enabled repairs and outfits to be completed with despatch and economy.

With regard to the manufacture and supply of guns for the Navy, the First Lord admits that that has been fairly satisfactory; but on this point he remarks that the Admiralty speaks on ordnance questions as users of the articles supplied, and is not responsible either for the design or manufacture of the weapons with which they are armed, except so far as gun mountings and torpedoes are concerned. Every gun on board ship has, after it has passed proof, to be tried with full service charges by naval officers, to test the gun mounting upon which it is placed. Every gun so passed, with its mounting, is tested once a quarter when in commission, and the charges fired are heavier than those in use in other navies. The experience thus gained by naval officers during the past four years in the practical use of modern breech-loading guns is unique. It is satisfactory to find that the absolutely unanimous evidence of all so engaged is highly favourable to the quality of the guns they have been handling. There is a considerable number of other subjects relating to the Navy taken up by the First Lord of the Admiralty in the statement which accompanies the Estimates. The only one, however, in which we are specially interested is that relating to the machinery of the ships. That, however, is of so much importance, that we have not space here to deal with it at length. We therefore defer our remarks for another occasion.

THE EFFICIENCY OF THE MERCHANT SERVICE.

Every industry in the country depends to a greater or less extent on the efficiency of our merchant marine, and whatever tends to improve that efficiency should receive our earnest attention. Lord Brassey is well known to have made a special study, not only of the affairs of the Navy, but also of those relating to the mercantile marine, and any suggestions he has to make on either of those subjects are always found to be worthy of careful consideration, and his thoughtful paper in the current number of the *Nineteenth Century* contains information, opinions, and suggestions which deserve the careful attention of all who can in any way, either directly or indirectly, influence the condition of the merchant service, and on a few of the more important points we propose to dwell shortly.

Lord Brassey first discusses the character, conduct, and efficiency of the British seamen of the present day, and he quotes the opinions of several authorities. It is probable that the late Mr. Gray, of the Board of Trade, was very near the truth in saying: "There can be no doubt that officers, and the better part of the seamen, as well as the ships themselves, have immensely improved." British seamen have more distinctly become separated into two classes. The bad may be worse, but the good are better. The late Mr. W. S. Lindsay was of opinion that it was not the case that either our ships or the officers by whom they are navigated have deteriorated, but that, on the contrary, they have during the last quarter of a century vastly improved in almost every respect. Lord Brassey himself finds, from his own experience during the past thirty years, that there is no deterioration, whether in discipline or in seamanship. The Royal Naval Reserve, which may be considered the cream of the merchant service, contains, according to the reports of the admirals in command, the finest body of seamen that could be got together. On the whole, the collective verdict of the Commission on Loss of Life at Sea may be taken as representing the evidence on the matter. It says: "After giving our best attention to the subject, we are unable to come to the conclusion that there is any just foundation for the allegation that British seamen have deteriorated in quality. We feel satisfied that shipowners who offer continuous service at good rates of pay have no difficulty in finding as good seamen as were ever in the merchant service in past times. . . . . There is a general concurrence that British seamen, even when inclined to be unruly in ordinary times, have, in times of emergency, courage, coolness in the presence of danger, and resources which are not to be found in their more submissive mates from abroad." Lord Brassey enters into the consideration of the difficulties and dangers, both moral and physical, which attend a sailor's life, and mentions some of the measures which have been passed for alleviating them. We cannot at present enter into these, but would mention that he strongly advocates a well-established pension fund for seamen, and states that they have a special claim to receive generous treatment from the State.

Lord Brassey treats of the education and professional training of the officers of the mercantile marine, and, while admitting that many of them would be ornaments to any profession, on the quarter-deck, as on the forecastle, there is a residuum little worthy to hold certificates or to fill commands, and he quotes the opinion of Captain Methven, that the mode in which navigation was conducted in a portion of our merchant service has been discreditable to our country. This opinion was confirmed by Mr. Rothery, the late Wreck Commissioner, who told the Commission that he had had cases of certificated masters who did not know how to lay a ship's course properly on the chart, or how to make the requisite allowance for tides or currents, and who knew scarcely anything of compass deviation. This, in our opinion, arises in great part from the too great importance which has hitherto been given to mere examination, apart from the education of seamen. It is well known to all who have looked into the matter that the ordinary examinations of the Board of Trade are samples of cram which are not surpassed anywhere. A class of men has arisen whose work it is to stuff into the candidates as much information as they can in a short time preceding the examination, which, as soon as it has served its purpose, is forgotten.

The late Mr. Gray, of the Board of Trade, recommended an entire revision of the present classification of masters and mates, and that only those should be styled captains who could pass in the subjects of the extra examination. He thought that if a regulation were made that such men alone should be entitled to command large passenger ships, it would raise the status of the mercantile marine generally. No doubt it would, but if more efficient arrangements were made for systematic training the process would be much more satisfactory, and Lord Brassey directs attention to the want of any organised system for professional training. He points out that, while a university has been created for the higher scientific training of officers of the Royal Navy, the Government renders no assistance in the education of the mercantile marine, and he suggests that the facilities which we have created at Greenwich might be utilised for this purpose by the professors giving lectures in London. Such aid as could be afforded by the naval university would, however, only be available to students who had served at sea. In the preparatory stage of apprenticeship the conditions usually found in the merchant service leave much to be desired. The training ships "Conway" and "Worcester" are doing excellent service for youths of from thirteen to sixteen years of age destined for the sea, but the subsequent stages of professional training have not been followed up. In a few ships only apprentices are carried, and, as a rule, the benefits they receive do not correspond to the high premiums which have been paid for them. The majority of the future officers of the merchant service commence their careers as apprentices, and receive no systematic instruction in professional subjects. A little desultory reading, combined with their practice at sea, and the hurried cram which they get when a few weeks on shore, enable them to get through the Board of Trade examination, but comparatively few of them can claim to be well educated. No doubt it is difficult to combine good theoretical training with practice at sea, but still a great deal could be done if more systematic instruction were given in secondary schools in those subjects which were preparatory to the more strictly professional training. Lord Brassey has decided to make an experiment. With the assistance of Messrs. Devitt and Moore it is proposed to make special arrangements in two sailing ships for the instruction of officers. Twenty-four midshipmen will be carried in each ship. A naval instructor will be appointed, who, under the supervision of the captain, will teach navigation and exercise control in all matters of discipline. The dietary will be on a scale approved for the junior officers of the ships, and it is hoped that the boys, instead of forgetting their preliminary training in theoretical subjects, will extend it, and after four years' service will have little difficulty in passing a satisfactory examination by the Board of Trade. We think that Lord Brassey's experiment is on the right lines, and we trust that he will receive sufficient encouragement to induce others to follow the example he has given, and thus turn out numbers of men who are thoroughly trained for the highest positions in the mercantile marine, in the continued success of which our industrial prosperity so much depends. Lord Brassey considers other subjects connected with the merchant service, especially those relating to its *matériel*, insurance, compulsory load lines, and surveys.

BRITISH INVESTMENTS IN MEXICO.

For some years past the low rate of interest in this country has been sending a large amount of capital to foreign countries, and especially to North and South America. Of these Mexico has been one of the chief favourites. Being one of the largest producers of silver, it has been looked upon as a kind of El Dorado, while the distance is too great for people to go and judge for themselves of the soundness of their investments. The unscrupulous promoter has therefore an admirable field for his operations in Mexico, and in many cases he has taken advantage of it. From a paper upon the finance and land investments of the country, which has been sent from the British Legation by Sir Francis Denys to the Foreign Office, we see that the British capitalist has been investing largely in Mexico. In 1886 there were 11 companies formed in London for undertakings in Mexico, with a registered capital of £2,555,000; in 1887 there were 15, with £5,135,800; in 1888 there were 25, with £10,956,020; and in 1889, up to November 9, there were 26, with £14,343,370, thus giving a total of 77 companies, with a total registered capital of £32,990,190. This enormous sum has been invested in railways, lands, mines, public securities, banks, &c., and Sir Francis Denys says that this tremendous mortgage on the resources of the Republic renders the maintenance of public order a matter of almost as much importance to Great Britain as to Mexico itself. The railway system of the country is almost entirely in the hands of British capitalists and investors, the Mexican Railway is an English Corporation, the control of the National line is in English hands, the Interoceanic and Mexican Southern are also English companies; the Tehuantepec Railway is being constructed with British capital, and it is stated that the majority of the first mortgage bonds of the Central Railway have passed into English hands. Sir Francis Denys gives a considerable list of other works which are being carried out chiefly by British capital, and concessions of all kinds are being granted by the Mexican Government, and he thinks it probable that the London market will be flooded more and more with schemes of all kinds for extracting money from the British public. The point, however, to which we wish to direct special attention is that all this British money has not been employed in floating new undertakings, but to a considerable extent represents a process of transference, for, except as regards mines, American capital and control have been gradually withdrawn to make way for those of our own countrymen. Sir Francis Denys, therefore, recommends that every caution should be employed before concessions are taken up second-hand, and especially that the securities offered for local, State, or municipal loans should also be closely scrutinised in view of the existing mode of taxation. At the same time he is of opinion that Mexico is undoubtedly advancing rapidly in material prosperity; the administration has a strong hold on public confidence; and, if proper caution and discrimination are exercised, there need be no fear on the part of the public abroad in embarking under the present Government in those mining, agricultural, or financial enterprises which offer reasonable prospects of success.

SHIP PROPULSION BY MULTIPLE SCREWS.

Steamship propulsion by twin or triple screws has not made that general progress which experience with the twin-screw ships already in existence would lead one to expect, but a forward impulse will in all likelihood be given to this branch of marine propulsion by the adoption in practice of an ingenious arrangement which Mr. Hugh Dunsmuir, of Messrs. Dunsmuir & Jackson, of Govan, has recently patented, and which his firm, as a trial arrangement, are about to fit into a small vessel for Indian coasting service. The arrangement in question consists in driving multiple (two, three, four, or more) screw propellers by means of one set of direct-acting triple or quadruple expansion engines placed crosswise in the vessel to be propelled. Each engine or cylinder is designed to drive its own shaft and propeller, but the crank-shafts of all the engines are effectually joined together by side connecting rods, cranks, or discs, in a somewhat similar manner to the side rods of a locomotive engine. In this way the two, three, or four cylinders are combined into one engine, thereby procuring all the benefits due to a multi-cylinder engine, with cranks set at equal angles, and at the same time giving choice to adopt twin, triple, or quadruple screws as may best suit the type of vessel.

Hitherto the chief obstacles in the way of the adoption of twin screws—even in vessels, such as broad light-draught craft, which specially lend themselves to the system—have been more of a commercial than of a

Digitized by Google

practical engineering character. The necessity for duplicate sets of engines, with all their various parts and complicated details, the great additional first cost, the more expensive upkeep, the extra engine-room staff entailed, and the extra space taken up in the vessel are considerations which have stood largely in the way. The liability, also, of twin screws to get damaged when vessels are being taken out of and into docks, or when taking the ground, has also materially influenced owners in rejecting the system. The engines under notice, however, will obviate mostly all of these objections. They may be fitted with the same facility, and nearly the same cost, as an ordinary set of single-screw engines. Being placed athwartship they will only occupy about half the space usually taken up by engines placed fore and aft. The several propellers being worked by one set of direct-acting engines, there will consequently be, in addition to the saving in first cost and in valuable cargo space, much less deadweight to carry, greatly less tear and wear, more economy of steam, oil, &c., and less labour to attendants. This arrangement will also give greater freedom to shipbuilders and shipowners in designing their vessels as regards draught, speed, and economical propulsion. The use of two screws has beyond doubt, during the past four or five years, come more into favour for large and fast ocean-going steamers, as well as for light-draught coasting and other steamers. In the Navy the practice is quickly displacing the use of the single screw, as our naval authorities have found, from repeated trials during the last few years, that two small screws are more efficient and give better results in manœuvring and direct speed than one of large diameter having equal surface. Owners of large passenger ships, also, have found it safer and equally efficient and profitable to adopt twin screws, and owners generally may soon find it preferable in all essentials to adopt two or three small screws, well emersed in solid water at all draughts, than one of large diameter with its top blade working half out of water when in ballast trim or half loaded, thus greatly destroying its own efficiency by drawing down air and wasting engine power. But there is, of course, a limit to the reduction of diameter with one propeller, as enough blade surface must be left to propel the vessel. With twin screws, however, the diameters can be greatly reduced, and with triple screws propelling surface can be got with smaller diameter still. It also follows that the adoption of smaller screws results in more revolutions, more piston speed, more relative power, shorter strokes, lower and lighter engines, and more efficiency in the engines as well as in the propellers, with reduced weight and space occupied, and greater economy throughout. We hope in a future issue to give details and illustrations of this system of propulsion.

THE COAL CRISIS.

The precise number of miners idle in Lancashire, Yorkshire, and the other districts affected by the strike is difficult to estimate, but 200,000 will hardly be regarded as an extravagant figure. This, however, by no means represents the number of persons affected by the strike, for coal at famine prices in London and in the manufacturing centres of England means that hundreds of thousands of persons suffer both from want of work and from the payment of the high rates. The holders of stocks have gained enormously, especially the London Coal Ring, which seems to be taking full advantage of the situation. The claims of the men for an advance of 5 per cent. immediately and another advance of 5 per cent. on the 1st of July have been met in some few cases, but the majority of the coalmasters hold out against the claims. So far as the claim for an immediate advance of 5 per cent. is concerned, it is likely that no serious disadvantage to the mine owners would have resulted by the concession, although in many cases it could only be given at a sacrifice. It is understood that the bulk of existing contracts for coal will have run off by the end of May, and a judicious compromise might have enabled the masters to arrange an advance in such a way as to save themselves from serious loss even upon old contracts. The second claim, for an advance of 5 per cent. to come into operation on 1st July, is, however, quite another affair. The price of coal at that date is much too problematical a quantity to deal with at this stage. The opinion on the Continent, derived from leading coal merchants there during the past few days, is that prices will fall as the summer advances. Instead of being disposed to increase their limits, even with the knowledge of the state of affairs in this country at the moment, foreign importers are actually even now diminishing them. Circumstances may conspire to falsify these forecasts, but the want of elasticity in prices now to be obtained for forward delivery of coal for exportation must have a certain influence on the wages question. It is understood that the railway coal contracts do not generally expire till June, so that till then the coalmasters who have not stock are on the horns of a dilemma. They must supply coal against contract, or suffer loss through damages for breach of engagement, or they must accept the situation. It is to be pointed out, however, that the districts presently most affected by the strikes are not so much exporting districts as home-trade districts. The home trade in coal—about six-sevenths of the whole—is, after all, the most considerable factor, and here the shoe pinches very hard at the moment. It is one of the curious incidents of a series of strikes over a great number of industries that the inconvenience is slow in becoming manifest. The contemporaneous strikes of the dockers at Liverpool, of the engineers on the North-East coast, and numerous other strikes of less importance, in the aggregate involving the idleness of a great amount of machinery and of a large number of men, have lessened the demand for coal so materially that the pressure is less great than it would otherwise have been. So far as domestic coal is concerned, the demand is also lessened owing to the mildness of the weather. In Yorkshire, in Staffordshire, and in Lancashire mills are everywhere stopping, and men are being thrown out of employment. The influence of this extensive dislocation of industry upon the demand for commodities must be immediate and enormous, and there can be no doubt that, even though the strike should last no longer than a few days, a very serious check has been given to the expansion of trade. In one or two districts, where Wages Boards have been in existence, work goes on as usual. The moral of this whole series of disturbances is that the industry of the country cannot be allowed to be dislocated by the quarrels of employers and employed. The establishment of Boards of Arbitration is indeed the paramount necessity of the time.

THE LATE MR. THOMAS GRAY, C.B.

We regret to announce the death of Mr. Thomas Gray, C.B., of the Board of Trade, who died on the 15th inst. at Rokesley House, Stockwell, at the age of 58. Sir Thomas Farrer sent to the *Times* the following notice of his old friend and colleague:—"By the death of Mr. Thomas Gray, of the Board of Trade, the public have lost an excellent servant and his colleagues an old and valued friend. The many Presidents whom he has served—the Duke of Richmond, Lord Norton, the Speaker, Mr. Stanhope, Mr. Shaw-Lefevre, Mr. Chamberlain, and Mr. Mundella—would, I am sure, bear willing testimony to his merits. He was one of those men whose energy would have made a mark in any sphere of life, and who, if engaged in business, would probably have amassed a large fortune. He was the son of a poor man who gave his son something better than wealth—a strong character and a sound, practical education. He came into the Board of Trade about the year 1851 as a boy clerk at 15s. a week, was attached to the Marine Department, and won his spurs by making himself master of the business of surveying steamships—a branch of work to which he always remained much attached. There was something of genius in his rapid comprehension of mechanical problems, and his knowledge of ships and their machinery was as accurate and extensive as that of a shipbuilder or marine engineer. Few persons have such capacity as he had for making the technicalities of these subjects intelligible. The Duke of Richmond, when he came to the Board of Trade as President, used to say that after an hour with Mr. Gray he felt that he had been all the time in the inside of a ship. But he was not a mere specialist. In all subjects connected with the mercantile marine and with the welfare of seamen, in the abolition of crimping, in the improvement of officers, in wreck inquiries, in the commercial code of signals, in all the legislation and administration arising of Mr. Plimsoll's move, he took a leading, helpful, and useful part. The rules of the road at sea he made almost his own, and his rhymes on that subject are as well known among seafaring men as 'Rule, Britannia,' and have been translated into all languages. Like all energetic men, he was fond of power, and sometimes overshot the mark; but he was always public-spirited, loyal, and invaluable to those who trusted him. He was insatiable of work, and drew too largely on his powers. His holidays were work in another form—rough voyages, exposed to hardships in search of practical information to be used in his official duties. His place brought him into inevitable contact—not infrequently collision—with shipowners, sailors, and engineers. But I believe there are few among them who will not now join with me in recognising his devotion to the public service, his energy, and his very peculiar and unusual knowledge of the subjects with which he had to deal."

Letters to the Editor.

PLATINUM FOR ELECTRICAL PURPOSES.

To the Editor of "Industries."

Sir,—Can any of your readers give me an approximate idea of the quantity of platinum annually used in the industrial applications of electricity? For what purpose is it principally used in this connection?

Yours, &c.,
W. M.

Newcastle-upon-Tyne, 18th March, 1890.

FORTHCOMING SILK EXHIBITION.

To the Editor of "Industries."

Sir,—I am requested by the Council of the Silk Association of Great Britain and Ireland, and also by Lady Egerton of Tatton, the Hon. Sec. of the Ladies' Committee of this Association, to ask you to be kind enough to insert the accompanying preliminary announcement of the forthcoming Silk Exhibition, and also the report of the Ladies' Committee.

Yours, &c.,
Thomas Wardle, President.

The Silk Association of Great Britain and Ireland, Society of Arts, Adelphi, London, 14th March, 1890.

Silk Association of Great Britain and Ireland.

Report of the Ladies' Committee of the Silk Association for the year ending February 28th, 1890.

The Ladies' Committee report that they have been, through their Honorary Secretary, in constant communication with the President of the Silk Association during the past year. They have also attended two meetings of the Silk Association, at which they urged the importance of holding an Exhibition of Silk Manufactured Articles, which would give an opportunity of verifying the improvement in English manufacture. Two causes have prevented this Exhibition being, as was hoped, held this year—the difficulty of obtaining a suitable building, and the desirability of giving a longer time for the production of the articles.

The Ladies' Committee consider that popular attention should be drawn to the improved and improving condition of the silk industries in the British Isles. It is patent to all that furniture silks can be, and are, made in England, which will bear advantageous comparison with those produced in other countries, both as to excellence of material, beauty of colour and design, and cost of production.

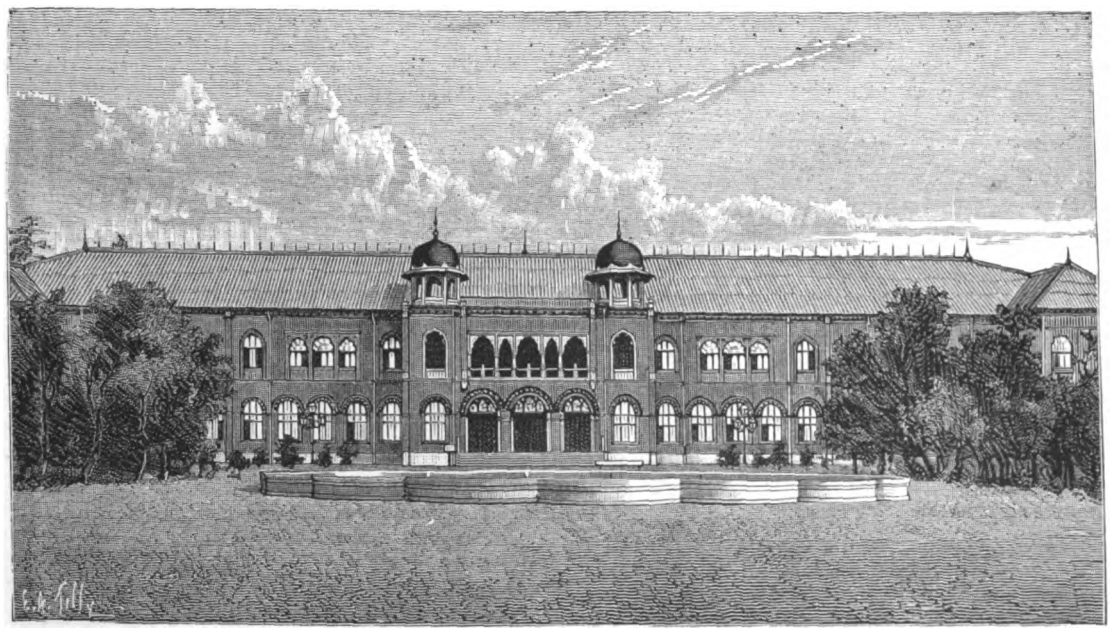
It is the belief of the Ladies' Committee that in other branches of the silk industry similar excellence is or might be attained, though for various reasons the goods now made are not always recognised as of British manufacture.

It is not within the province of the Ladies' Committee to inquire and enter into the vexed questions affecting industrial and mercantile prosperity, but seeing that for the first time the silk manufacturers and others interested in this industry have formed a representative association, which is a guarantee both of good faith and of united action, this committee, formed at the request of the Silk Association, consider that the time has come to invite the attention of the ladies of England to the revival of this ancient industry. In order to do this the committee propose to form a Ladies' Silk Association on an extended scale. Its members will not be pledged (any more than are the members of the Ladies' Committee) to the exclusive purchase and use of English-made silks but they will be asked to interest themselves and their friends in this British industry, and to make inquiry for and inspect English silks before deciding to purchase those of foreign manufacture.

In conclusion, the Ladies' Committee of the Silk Association trust that before long ocular demonstration of the excellence of English silks may be afforded by an Exhibition; and should success crown the efforts of those who have been working on behalf of the silk operatives of England, Scotland, and Ireland, they will feel rewarded by the knowledge that the time and energy they have devoted to this enterprise have resulted in increased material prosperity to their working brothers and sisters in silk factories.

Mary Adelaide,
President of the Ladies' Committee of the Silk Association.

At a meeting of the Ladies' Committee, held at 7, St. James's Square, London, on March 1st, H.R.H. Princess Mary presiding, it was resolved:—



> "That a small Loan Exhibition of British-made Silks be held by the Ladies' Committee early in May this year, subject to the approval of the Silk Association, and that Lady Egerton of Tatton be requested to communicate with the President of the Silk Association on the subject."

In consequence of this resolution the Council and Exhibition Committee of the Silk Association met at the Society of Arts, London, on Friday, the 14th inst., Mr. Wardle, F.C.S., F.G.S., President, in the chair. It was unanimously resolved to adopt the resolution of the Ladies' Committee, and to cordially co-operate with them in the carrying out of the Exhibition, which it is proposed to open on or about the 6th of May next, and to be open for a fortnight. Lord Egerton of Tatton has kindly offered his large ball-room, at 7, St. James's Square, for this purpose. It is intended that the Exhibition shall be as representative as possible, and, whilst the more ornamental silks for dress and household decoration would naturally form the most important part of the Exhibition, all the various branches of the silk industries of Great Britain and Ireland, it is hoped, will be adequately represented both through the manufacturers and distributors.

Intending exhibitors are requested to communicate as soon as possible with the President, addressed to Leek, Staffordshire, who will supply conditions and all particulars.

JAPANESE EXHIBITION AT TOKIO, 1890.

DISCOVERY OF COAL IN KENT.

We recently gave a short account of the find of coal near Dover, as obtained from the report of Mr. F. Brady. The connection of Professor Boyd Dawkins with the experimental borings is well known, and we note with some interest that he read a paper on the subject at the last meeting of the Manchester Geological Society, held on the 11th inst. The Professor is inclined to be cautious in making the details of the "find" public, although he expresses himself as quite confident that the true coal measures have been struck. We shall have a further opportunity of noticing Professor Dawkins' opinion when he lectures on the same subject at the Royal Institution at the beginning of June, but in his recent paper Professor Dawkins said that as yet he was only in a position to give a first sketch of an unfinished work, as obviously the promoters of the undertaking did not intend to publish a complete account until the work was finished. The question, however, of the existence of the coal measures under the newer rocks of South-Eastern England had now been proved beyond all doubt by the boring that had been undertaken by Sir Edward Watkin, acting under his advice. The hypothesis that the coal measures lay at workable depths under the tract of country which intervenes between the several coal-fields of South Wales, Somersetshire, Belgium, and the North of France, was started by Mr. Godwin Austen, thirty-five years ago, and, although opposed by Sir Roderick Murchison, was considered by the Coal Commission of 1866. Up to 1872, however, it was only a matter of theory, but in that year it passed into the experimental stage, when a committee organised by Mr. H. Willett conducted a trial boring near Battle, in Sussex. This work was abandoned after passing through 200ft. of Purbeck shale and 1,705ft. of oolitic rocks. From the fact that the bottom of the bore-hole was in the Oxford clay it would appear that the eroded surface of the coal measures at that point was over 2,000ft. deep. In 1886 Sir Edward Watkin commenced the present bore-hole at Shakespeare Cliff. This work, carried out by Mr. F. Brady, has passed through the following section:—

Cretaceous rocks	500 feet
Oolitic rocks	660 „
Coal measures, sandstones, shales, and clays	20 „
	1,180 „

The coal measures were struck at a depth of 1,160ft., and on the 15th February a seam of blazing coal was found at 1,180ft. Considering that most of the important collieries in Lancashire raise coal from depths between 2,000ft. and 3,000ft., and in Belgium and the North of France from still greater depths, a coal-field had thus been proved in South-Eastern England at the comparatively shallow depth of 400 yards. The amount of coal that might be expected to exist under the newer rocks might be estimated by comparing the coal measures of Somersetshire, Namur, Mons, and Douai. In the latter coal-fields the thickness of the coal measures was 9,400ft., and the thickness of workable coal was 240ft. These measures, coming to the surface from underneath the same rocks as those in Somersetshire, had been traced to within thirty miles of Calais, and in general direction made straight for Dover. It was too soon to measure the full importance of the discovery, but the proving of these concealed coal-fields was a question of national importance, well worthy the attention of Parliament.

THE INSTITUTE OF MARINE ENGINEERS.

A meeting of the Institute of Marine Engineers was held on the 11th inst., in the Langthorne Rooms, Stratford, when Mr. E. L. Morgan read a paper on "Coal." The author began by noticing the earliest records of coal being used for fuel, and then went on to mention such epochs in the history of coal as (1) its introduction for domestic purposes; (2) its condemnation by the citizens of London for polluting the atmosphere of the City by its smoke, and its use forbidden; (3) its re-introduction in consequence of the scarcity of wood; and (4) the use of coal for smelting iron and steel. He also discussed the question as to which quality of coal is best for use in steamships. The stowing quality of the block fuel, both in respect to ease in handling and cleanliness, appeared to give it a great advantage, and in addition it was made from the accumulated waste at collieries, and should therefore be cheap. The evaporative power and the qualities of the different kinds of coal, and the suitability of each kind for the various purposes for which coal is used, were carefully entered into, and the paper concluded with a reference to the introduction of oil for fuel as well as for lighting purposes.

In the discussion which ensued the various speakers dealt with the evaporative power of the various kinds and qualities of fuel under natural or forced draught, from which it appeared that under certain conditions of stokehold and boiler arrangement north country coal gave equally good results with Welsh, while in several cases cited the block fuel appeared to give results in no way inferior to good steamship coal. Reference was made to a new patent fuel to be placed on the market soon; it appears to be a composition of petroleum manufactured into a solid state. Several speakers pointed out that a very grave mistake was made by manufacturers of patent block fuel in not keeping up the quality of the fuel. The theory of heat and combustion was also dwelt upon.

LONDON ASSOCIATION OF FOREMEN ENGINEERS AND DRAUGHTSMEN.

Mr. W. H. White, Director of Naval Construction, presided, on Saturday evening, at the Cannon Street Hotel, on the occasion of the thirty-seventh anniversary festival of the above Association. In addition to the Earl of Ravensworth and Admiral Mayne, M.P., there were also present the representatives of the leading engineering firms in London and the provinces. In proposing the toast of the evening—"Prosperity to the Association"—the Chairman said it was impossible to over-estimate the value of such an association. Its objects were threefold—social intercourse, technical instruction, and benevolence. Standing, as foremen engineers did, intermediate between the employers and workmen, they naturally looked very much to their own ranks for friendly association and the pleasures of life, and that association was offered by the monthly meetings of that society. He owed a very great deal to the foremen and draughtsmen who had worked out his designs in the past and had always given him the benefit of their constant help and loyal and generous assistance. And what was true in his own experience was, he was sure, true in every workshop, when they reflected how much a design gained in its execution by the intelligent assistance of the foremen, and the cost of production was affected by comparatively little things. If that was so, how important it was that those who occupied such positions should not be content simply with what might be called mere workmen's knowledge, but should add to that technical culture; and he could conceive nothing more beneficial in that direction than the technical papers which were read, and the technical discussions which took place, in connection with that Association from time to time. To put into precise terms the ideas floating in one's mind was in itself an education, while the difference of opinion which arose in the treatment of any engineering subject was a further step in education and a distinct gain in knowledge. During the past year they had many valuable papers read to them by experts in various departments of engineering; and the fact that such men were content to place before them their thoughts and ideas was the highest testimonial which the Association could receive of its value to public life. Nor was that all. Engineering was a pure democracy: there was always an upward movement from the ranks to the leadership, and they who were engineers in any of its branches knew that it was for the best that that should be so, and that anyone who had the necessary ability, energy, and perseverance should be also able to rise. And then, with regard to the benevolent department of that Association, he pointed out that, besides the superannuation fund for old members and the assistance given to unemployed members, they had also a widow and orphans' fund, so that, should any member of that Association fall on evil days, they would know that the Association would not desert them in the time of their greatest need. He sincerely trusted that so excellent an Association would continue to flourish, and that its funds would be largely increased as the result of that gathering.

JAPANESE EXHIBITION AT TOKIO, 1890.

We give above a view of the principal building in connection with the forthcoming Japanese Exhibition which is to be held at Tokio during the present year. The site selected for the Exhibition is situated in the Uyéno Park, which is one of the most beautiful parts of Tokio. We hope soon to be able to place before our readers plans of the several Exhibition buildings, as no doubt great interest will be taken by many Europeans in this Exhibition. We are indebted to our contemporary, *La Nature*, for our illustration.

SHIPBUILDING NOTES.

The s.s. "Bremerhaven," which was recently launched by Messrs. Russell & Co. from their Greenock yard, was taken on her trial trip on the Clyde on the 14th inst. Her dimensions are: Length, 340ft.; beam, 42ft. 8in.; depth, moulded, 27ft. 4in.; and she has been specially designed for the carriage of petroleum in bulk between America and the Continent. For this purpose the holds are divided into numerous watertight compartments, or tanks, each of which has been severely tested by a head of water before launching. She is capable of carrying upwards of 4,000 tons of oil in addition to bunkers, and is, therefore, one of the largest, if not the largest, bulk steamer afloat. There are two very large oil pumps, made by the Worthington Company, of New York, each of which is capable of discharging the entire cargo in 24 hours, and as all the piping is duplicated, both pumps can discharge at once if required. Two large donkey boilers are fitted to supply them with steam. This is the fourth vessel by the same builders for Messrs. Hermann Stursberg & Co., of New York, and, like her predecessors, she has been built to the designs of Messrs. Flannery & Blakiston, of Liverpool and London, who also superintended the construction of the vessel and her machinery. In addition to receiving the highest class at Lloyd's, the Bureau Veritas have registered her with their special mark denoting that she is practically unsinkable. The engines are by Messrs. Duncan Stewart & Co., of Glasgow, with cylinders 25in., 40in., and 66in. diameter, and with a stroke of 42in. Steam will be supplied by two extra large double-ended boilers having 4,800 square feet of heating surface. Four runs were made on the measured mile at Skelmorlie, when a mean speed of close on 11 knots was obtained.

IMPROVED WENSTRÖM DYNAMO.

We illustrate herewith a Wenström dynamo of the latest type. Its output is 110 volts and 180 amperes at 500 revolutions per minute. Its weight is 1,800 kilogrammes, or under 2 tons. It has four poles, with the armature conductors in series parallel.

Mr. Wenström was the first, or, at least, one of the first, to imbed the armature conductors in the iron of the armature. He has apparently arranged the field magnets on the ironclad principle. We would suggest that this is a pity, as it prevents ventilation without any compensating advantage.

These machines have been very thoroughly tested in America at the John Hopkins University. They give very good results. It must also be remembered that the method of winding the armature conductors admits of great mechanical strength and durability. These machines are made by the Wenström Southern Electric Manufacturing Company, Baltimore, and are very largely used in America.

SAFETY IN ELECTRICAL DISTRIBUTION.

By James Swinburne.

II.

(*Concluded from page 259.*)

Direct Supply on Low Tension.—In this case direct currents are always used, though there seems no reason why alternating currents should not be employed where batteries are not used. On the two-wire, and perhaps on the three-wire system, danger to life need not be considered. There can, of course, be danger from fire.

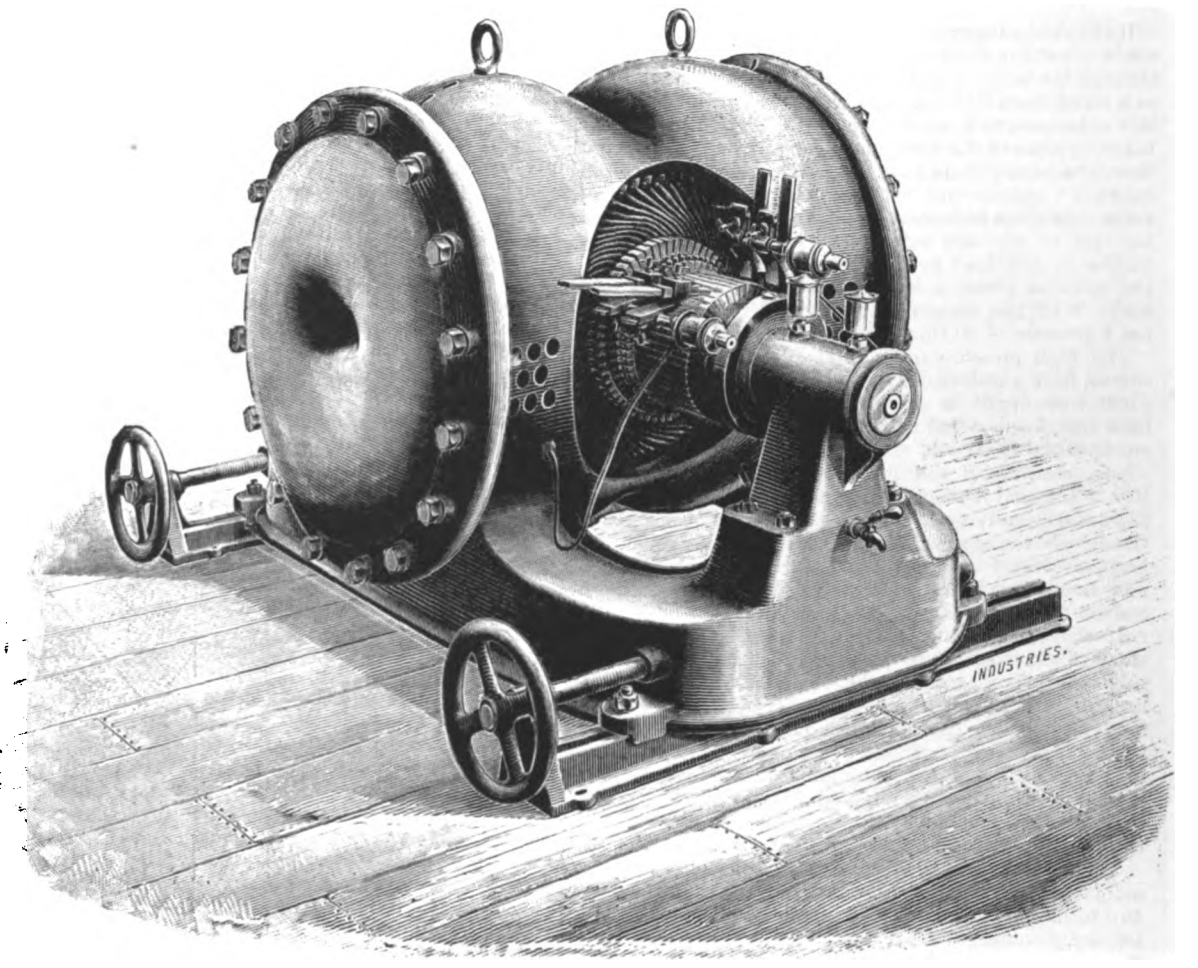
In the case of the two-wire system a leak-finder with an earthed middle connection may be used to show that there is a leak; but that is all it can do, for, though it might be advisable to shut down an arc circuit as soon as a fault occurred, especially as the lamps on one circuit are frequently arranged alternately with those on another, it would be impossible to shut down a direct current supply station directly a bad place began to show in some private house. It would be like shutting down a gasworks whenever some one left an unlighted burner turned on. It is no easy matter to localise a fault on a large parallel circuit which is under pressure all the time. The question of localising such a fault, whether possible or not, is outside the present subject. It would seem as if the simple direct current supply low tension system may be really the most troublesome to protect from fires. Of course it takes two faults to cause a fire, though a large general leakage might act as one; but if, on the alarm being given by the first fault, nothing can be done to find out where it is except cutting the houses off one at a time and testing their circuits, there seems to be little to be done until another fault shows somewhere else, and evidence of mischief gives the clue. It may be possible to localise a fault in a direct current system by superimposing an alternating current on the direct current through the leak, and awaiting notice of disturbance from the telephone companies. The telephone might also be applied directly for more nearly localising the leak. Of course, nothing has been said about the safeguard, which consists in putting in good wiring to begin with, and in periodically testing the various consumers' premises. The same difficulties in localising faults, after their existence has been made known, are to be met with in the case of three and five wire disturbances. When batteries are used, and charged in series, and discharged in parallel, the leak-finder, like that discussed in connection with series arc lighting, will detect any failure in the high tension circuit. There are the same difficulties in the discharging circuits as in the case of direct supply already discussed.

Alternating Current Systems.—Alternating systems have received far more attention in the matter of safety than direct current systems, and not without reason, for the transformer is generally placed on the consumer's premises, thus involving the introduction of high tension leads. Even if it is not, there is always the chance of a contact between the primary and secondary circuits at the sub-station, which might result in fires or dangerous personal injuries. The ordinary supply system with a transformer in each house will be taken first.

Danger to life may arise if the primary makes contact with the secondary, and, at least in the case of 100 volt circuits, it is not impossible that a sensitive person who made very good contact might be seriously injured, if not killed, by the low tension circuit. Of this more will be said at a future date. A fire may occur from leakage of the secondary circuit to earth in two places, or by leakage between two neighbouring wires without any earth; or it may occur if the primary circuit comes into contact with the secondary and there is a ground leak on the secondary also. It must be remembered that if the primary were to make contact with the secondary it would probably also soon find its way to earth, as the secondary insulation is seldom fit to withstand 2,000 volts alternating.

The dangers from contact between the primary and secondary circuits may be lessened either by preventing the contact, or by making it harmless if it does occur.

It has been proposed by Professor E. Thomson and by Mr. Kent to surround the primary completely with a sheath of thin metal, and to earth this sheath. This seems a most admirable plan, as low insulation will protect the secondary from the sheath, and even if the secondary were to come into contact with it, and if the primary were to break down too, there would be no danger. It has been urged against this plan that putting an earthed sheath round the primary is tempting it to break down. This criticism is not valid, for if there is the same insulation between the primary and the sheath as there would otherwise be between the primary and secondary there is just as little chance of breakdown, for the low insulation of the secondary circuit is, in comparison, so low, that the primary could find earth practically as soon through the slightly insulated secondary as through the earthed sheath. Even if it were to cause a break down, or, to write more correctly, if a break down were to occur with the sheath, it would be harmless as far as the consumer is concerned.



Mr. Mordey strongly recommends earthing the secondary. If the middle of the secondary is earthed there can be no danger from leaks from the primary, as each of the secondary leads can only differ by 50 effective volts from the earth. There is one objection to earthing the middle of the secondary, and that is that it only requires a leak on one lead to cause a fire.

Major Cardew's arrangement and Professor E. Thomson's film and vacuum tube apparatus avoids this difficulty, as it only earths the secondary if there is a dangerous pressure between it and the earth—that is to say, if there is a leak from the primary to the secondary. Major Cardew, in his patent, proposed an arrangement so that if a difference of 200 or 300 volts existed between the secondary and the earth a simple little electroscope short circuited the secondary or primary, and thus blew the fuses on both poles, so that the house was immediately cut off. In practice the little electroscope is arranged merely to make an earth contact with the secondary if necessary, and thus to prevent any danger to life or fire if the primary makes contact with the secondary. This ingenious contrivance will do nothing to prevent fires from faults in the secondary circuit—in fact, it is not intended to do so; it merely prevents danger from the primary. Its advantage over a directly earthed secondary is that it takes two faults in the secondary to cause trouble in the secondary.

The automatic leak-finder is applicable to secondary circuits of transformers, and prevents all sorts of risk. The middle of the secondary is earthed through an electromagnet. The armature of this electromagnet, when attracted, releases a small double-pole spring switch in the primary circuit, and thus cuts the consumer's premises off completely. Take the various possible accidents and trace the action. If the primary makes contact with the secondary there is an earth circuit through a local leak-finder and the station leak-finder. The station leak-finder merely gives an alarm and shows that some house has been automatically turned out. Even if the local leak-finder did not work, the station earth circuit would be broken, so that there is still only one earth in the whole of the primary circuit; and the house is in the same position as if the secondary had been purposely earthed to begin with, or as if the electroscope apparatus was in use. There is no reason to suppose the automatic leak-finder is not absolutely to be relied upon; it is only for the sake of argument, and because the best designed automatic arrangements sometimes go wrong, that this contingency is mentioned. The automatic leak-finder seems to have immense advantages over other methods, as the alarm is given at the supply station, and the whole installation is kept without one leak.

Take next the case of a leak to earth from one secondary wire; the automatic leak-finder immediately cuts the house off. At first sight this might appear to be a rather heroic remedy, but the companies have power, or will have power, under the new regulations, to cut off a house if the insulation is bad, so it cannot but be advisable to cut a house off automatically as soon as a fault occurs, without waiting for someone to find it in his ordinary tours of inspection. If the double-pole switch which is controlled by the leak-finder is locked, the consumer must apply to the company before he can get the light again. It is to be borne in mind that this does not mean that every now and again a house should suddenly be left in darkness; if the insulation is looked after properly, such a thing should never happen. If the light is put out through a fault on the consumer's circuits he has himself to blame, as he is responsible for his leads, and has probably had them put up badly. If his lights are extinguished on account of a leak from primary to

IMPROVED WENSTRÖM DYNAMO.

Digitized by Google

secondary, he would have a claim against the company for not supplying him continuously. There is no reason why the primary should not be perfectly insulated from the secondary; and if it is not, the company, too, are in that case flagrantly at fault, and should have to pay a heavy penalty.

If the electromagnetic leak-finder is sensitive, it can be made to cut the circuit off even if a man makes an earth through his body. It is doubtful if this is really advisable, as a shock from 50 volts can hardly do him any harm. If this extreme sensitiveness is not needed, a small fuse may take the place of the electromagnet, as it is simpler, and therefore more certain to act. A fuse like this goes off between a quarter and half an ampere. Such an apparatus thus gives immunity from dangers to life and from fire due to currents running to earth. Earthing the middle of any lead has also another effect; it prevents the extreme pressure coming on the insulation of one lead. With this system, on a 100 volt circuit, each lead has a pressure of 50 effective volts.

The high pressure on a 2,000 volt circuit should, of course, have a leak-finder at the central station. If the 2,000 volt circuit is only intermediate, and is supplied from transformers fed at 10,000 volts, it is most important that the 2,000 volt circuit should be earthed somewhere, especially if the 10,000 circuit is itself earthed. For if not, and if the 10,000 volt gets into contact with the 2,000 circuit, it will easily penetrate the insulation of the house transformers, and will run to earth in the houses. Transformer insulations designed for 2,000 volts and house insulations meant for 100 will offer little resistance to a 10,000 volt pressure.

If the consumers are supplied from sub-stations instead of transformers on their premises, a leak-finder for each sub-station can be used. The difficulties of localising faults then come in, as in direct current supply systems. In this case the leak might be localised with the help of a direct current superimposed on the alternate current and passed through the leak. When there is no network the superimposed current system might be of considerable value, but it is more complicated in the case of networks.

It must be remembered that none of these arrangements provide security against shocks from touching two terminals, or even fires caused by leakage between two neighbouring wires, the whole leak being insulated from the ground. For instance, the leak-finder would not be worked by a short circuit across a double-pole switch on an insulated base.

There is another source of danger from transformers. If two neighbouring turns of the primary circuit come into contact, or, as more often occurs, if two neighbouring layers come into contact, they act as a short-circuited secondary on the transformer, and grow very hot. The neighbouring insulation is burnt, and more primary turns become short circuited until the primary fuse goes. This is not at all an unlikely contingency, for in many transformers there is a difference of pressure of some hundred volts between the neighbouring layers of primary wire. A 10-horse transformer, for instance, if the fuses are set to go at 15 h.p., will, if this accident occurs when there is no external load on, have 15 h.p. converted into heat in its primary coil before the fuses go. If not provided against, this may easily cause fires, and it is also not unlikely that when the whole apparatus is charring the primary and secondary may make contact, and that, as one fuse goes first when there is a gradual rise of current, they would be left in contact. In America one eminent inventor has patented an arrangement, in which he places his transformers in a sort of stove with a chimney, so that if or when this catastrophe does occur the products of combustion are carried away by the flue without setting the house on fire. In this country all danger will be at an end when the Board of Trade rules are enforced, and transformers are confined in fire-proof cases.

There is still one more source of danger, and that is from explosions of accumulated gas in culverts. When the attention of the Commons Committee was called to this danger, during the conflict of the electric light companies, it was generally considered rather far-fetched, but since then there have been several accidents through explosions of culverts. Some culverts are free from this danger, either because they are quite air-tight, or because they have no space for gas to accumulate. The remedy, where there is possibility of accident, is to ventilate the culverts. There are several ways of doing this, by blowers, exhaust fans, &c. One of the simplest, perhaps, is to arrange a ventilating post here and there with a resistance to cause a constant draught. As the resistance can be easily heated by being connected with the mains in the culvert, the cost is small. Of course the resistance itself must not be hot enough to fire any explosive gas that may be finding its way out. A few openings into cool cellars supply cold air and make a draught.

(To be continued.)

PRACTICAL WORKING OF THE ELECTRICAL SUBWAYS IN NEW YORK.

(From our New York Correspondent.)

(Continued from page 259.)

The Johnstone sectional conduit has hitherto been the most extensively employed for distribution in New York City. This consists of sections of cast-iron ducts about 5ft. in length. The sections are placed directly above each other, and are held together when in position by removable clamp pins. The upper section rests in a groove in the lower section. Each section of the conduit is divided into two, six, or more compartments or ducts—depending upon the size of the section, the ducts being formed by removable partitions or slats held in position by suitable channels or grooves within the sections. Opposite each house, or every alternate house, a hand-hole is provided in the upper section of the conduit. This hand-hole consists of a removable cover, about 2ft. in length, on the upper section, and the side of the section at this point is provided with a branch or spigot.

This conduit is laid directly in the earth, not in cement. When it is desired to obtain access to a conductor to tap or loop the circuit into a building, the paving and earth are removed from the street and the cover of the hand-hole is lifted, thus exposing the conductors in the ducts. A 3in. iron pipe is run from the branch at the hand-hole to the basement or vault of the house or to the lamp-post with which connection is desired to be made. This iron pipe fits on to the spigot at the side of the conduit. The connection is then made with the conductors by splicing on short lengths of cable leading through the iron pipe to the house or lamp. Should the conductor which it is desired to tap be at the side of the section remote from the spigot, the intermediate partitions are removed to permit the passage crosswise of the connecting cable. After the joints are made, the cover of the hand-hole is replaced, and the earth and the paving are restored to their normal condition. When a hand-hole has not been provided originally at a point where access is desired to a conductor in the conduit, the entire upper section is removed and replaced by a half-section containing a hand-hole cover and spigot. This work can be done in a short time. The sections in use for this purpose are in some instances somewhat small, for ease in joint-making especially, as but very little slack is available when T joints are to be made, and in future larger hand-holes will be provided. These conduits are presumably made air and water tight at the junction of the two sections, and at the ends of the ducts, by the use of plumber's putty. In view of the number of supposed opportunities for the entrance of moisture at these junctions, it would be naturally expected that this type of conduit would be in a chronic moist condition Indeed, it has been predicted of it that the ducts would act as canals for the surface water, but, as a matter of fact, these ducts are almost invariably dry. There are two theories given to explain this fact—the first, that in reality the plumber's putty makes an air and water tight joint; the second, that if the joints are so imperfect as to admit water, they are quite capable of permitting its escape also. It must be said that this system has been found of much utility in the practical distribution of electric light currents. Recently a method of distribution in which wrought-iron pipes are used has been employed, consisting of a row of three or four iron pipes laid like the Johnstone conducts as near the surface as possible, in the earth, without concrete. Opposite every party wall, or at intervals of about 50ft, iron boxes about 18in. square are placed. These boxes have removable covers. The ducts enter at the ends of the box, but do not pass through it. The boxes are provided with side openings also for the entrance of the subsidiary iron pipes. Access is had to these boxes also by the removal of the street paving and earth. This method of distribution has, like the one just described, been found satisfactory. Certain mechanical improvements in the construction of both are, however, desirable. When it is desired to cross a street to reach customers subsidiary ducts are constructed.

The cables used for telephone service are chiefly of the Patterson type, ordinary cotton covering being used. The conductors, after being cabled, are drawn into a lead covering, and paraffin forced into the interstices. The insulation resistance laid and jointed in the subways is about 100 megohms, and the electrostatic capacity about ·16 microfarad. The longest stretch of telephone cable is seven miles, and the greatest number of conductors a hundred or fifty pairs. The telegraph companies have used kerite, okonite, Waring, and Patterson cables. The kerite and okonite are india-rubber compounds, and not usually lead-covered, although they might be. The Waring and the Patterson have fibrous covering saturated with insulating compounds and lead-covered. The india-rubber insulation has given satisfaction, excepting in the vicinity of steam pipes where the heat runs as high as 200° F. The average number of conductors in the telegraph underground cables is about fifty. The size of the wire used is No. 16 B.W.G., and the outside diameter, including the insulation, $\frac{6}{32}$in. The insulation resistance of the okonite insulation is about 2,500 megohms, that of the kerite 500 to 800 megohms, and that of the Waring and Patterson about 1,500 megohms per mile for the thickness of insulation. Outside of the injury to the cables due to the presence of the steam heating pipes no undue deterioration of the telegraph cables in the subways has been noted. The effect of the increased electrostatic capacity of the underground circuits has not caused any marked inconvenience in the operation of the telegraph circuits. Most of the telegraph conductors are placed on the elevated railroad structures instead of in the subways.

In the electric light service there are, exclusive of the Edison system, four different types of insulation used—namely, the Bishop rubber compound, the Waring, the "Safety" insulated, and the Cobb vulcanite-paraffin cable. All of these cables are lead-covered, as a precaution against mechanical injury, action of acids, &c., or moisture.

The sizes of conductors used in the electric light service vary with every company and with the character of the service. For feeders the conductors range in size from No. 6 down to No. 2 American gauge. For mains, from No. 2 to No. 6 American. In many instances, No. 10 American is used for connecting from the mains to lamps through the subsidiary ducts.

There are now in actual service for electric lighting purposes in the New York subways over 95 miles of Waring cable, carrying currents of an e.m.f. of from 500 to 3,000 volts, including many 1,000 volt alternating currents, and an additional 50 miles of the same cable will shortly be in operation. The thickness of insulation used in these cables is $\frac{5}{32}$, $\frac{6}{32}$, and of $\frac{7}{32}$ an inch. This refers to the thickness of the insulation from any given point of the circumference of the conductor.

The insulating material of the "Safety" cable is an india-rubber compound. This compound is vulcanised to a moderate degree of hardness sufficient to prevent decentering of the heavy conductors which it insulates, but yet it retains a high degree of flexibility. The thickness of insulation used in No. 4, B. and S. wire, ·204in. diameter, is ·108in. The weight of this conductor, lead covered, is 4,861lb. per mile.

A special thickness of this insulation was made in one instance in response to a call for cable to withstand a strain of 7,000 volts for arc lighting. This cable is now in the subways. Its length is about three miles. There are now over 65 miles of the "Safety" cable in actual use in the subways, assigned to electric light circuits, carrying continuous and alternating currents of from 1,000 to 2,500 volts e.m.f., and about 15 miles additional are now being placed in subways.

The Bishop rubber compound cable is of the well-known Silvertown type; having first a coat of rubber without sulphur, then a coat of rubber compound with sulphur, and over this a lapping of rubber cable, which is then taped. There are two sizes of this cable in the subways, namely No. 4 and No. 6 American gauge. The thickness of the insulation is $\frac{4}{32}$in.; the thickness of the lead covering is $\frac{5}{64}$ of an inch.; the outside diameter of the cable is 0·65 of an inch.; and the weight of the cable is about 3,432lb. per mile. There are of this cable in successful operation about ten miles assigned to alternating currents of 1,000 volts, and five miles to arc circuits of 2,500 to 3,000 volts e.m.f. Double this amount of this cable will soon be laid for similar purposes.

The Cobb vulcanite-paraffin cable is of a unique construction and design. It also differs, materially in one respect, from the other cables described, in that the conductor is freely movable within its insulating medium. The cable is made in practically the following manner: A vulcanite tube is first made in lengths of about 300ft. This tube is moderately flexible. The tubing is vulcanised in boiling paraffin. The wire is then threaded through the tube, after which the sections of tubings are jointed together. A thick cord is then wound spirally around the vulcanite tube. The whole is then lead-covered, and the space between the vulcanite and lead formed by the spirally wound cord is filled with paraffin. There are about 25 miles of this cable in the subways.

In the case of the Bishop, "Safety," Cobb, and Patterson cables, the lead is alloyed with about 3 per cent. of tin. The lead covering of the Waring cable is unalloyed, but it is covered with a thick cotton braiding soaked in "P. & B." paint (the latter a product of petroleum), which, it is claimed, will protect the lead from acid gases, &c., and the braid also acts to protect the lead from mechanical injury.

All of these cables are guaranteed by the manufacturers for three years. This term, however, is not to be taken as signifying the limit placed upon the life of the cables by the manufacturers. It is over a year since current was turned on the first high-tension electric

Digitized by Google

light circuit in the New York subways. The insulation resistance of the cable, as measured just before the turning on of the current, showed it to be 1,750 megohms per mile. A test made of the same circuit, after one year's continuous service, showed an insulation resistance of 1,516 megohms. Since the installation of the circuit just referred to, electric light cables of the various types described have been drawn into the subways almost as rapidly as they could be manufactured, and tests made of the conductors, months after the initial test, have shown them to be in the same electrical condition as when first laid. There have been several burn-outs in cables in the subways within the year, but, with the exception of an abandoned type of cable, these burn-outs have been traceable in every case to defective joints or to mechanical injury. In all, according to the records, and best obtainable information, there have been, exclusive of those in the abandoned cables, but five burn-outs in over 185 miles of electric light wire during a period of active service of the conductors, ranging from one month to thirteen months. In the case of 27 out of 34 of the electric light circuits in the subways, not a single defect of any kind has occurred since they were placed in the ducts. There have been several instances when faults not amounting to burn-outs have been discovered by the regular tests, which have brought the insulation resistance of certain conductors below the requirements of the rules of the subway, but these defects have generally been located and removed without serious delay to the circuits. Where this has not been the case it can be fairly attributed to the employment of untried insulation, unfamiliarity with underground service, or to the inexperience of the men to whom the work of connecting up circuits, &c., has been entrusted. For instance, in a number of cases grounds have been traced to contact of the conductor with the lead covering, and the linemen so connecting them have explained that they were not aware the lead covering would cause a ground.

The method employed for locating faults in electric light conductors in the subways is to test the conductor from point to point until the defect is placed between two lamps or man-holes. When a fault is located between two lamps or two man-holes, if it is in the cable proper and not in a joint at a hand-hole or box, the defective section is withdrawn and a perfect section put in its place.

In the case of arc light or series circuits, defects in the cables are more readily located than in multiple arc circuits, because of the facility afforded by the openings at the lamps for testing the conductor in sections. In the case of multiple arc circuits, there is at present no means of locating faults but by cutting the conductor in man-holes. For, as the house connections are made from the cable by T joints, it is obvious that the only effect of disconnecting the lamps or converters from the cable is to separate the two conductors of the circuit. No attempt is made to locate faults in electic light circuits in the subways by electrical measurements, for the reason that the obstacles in the way of obtaining accurate data are so numerous that it has not been considered expedient to rely on the results of such measurements—for instance, the uncertainty as to the distribution of the resistance of the conductor, owing to the numerous joints in the circuit; the variations in temperature of the subways and the difficulty in ascertaining it, &c. To facilitate the locating of faults, should they occur in the subways, several forms of accessible joints have been suggested for use in the manholes.

(To be continued.)

THE INSTITUTION OF ELECTRICAL ENGINEERS.

At the adjourned discussion on Mr. Swinburne's and Mr. Esson's papers on the 13th inst., Professor Ayrton exhibited curves representing results of experiments on the Gramme magneto and Gramme dynamo when run as motors and generators, which he described on the 27th ult. From these observations, he concluded that Mr. Swinburne and Mr. Esson were wrong in saying that the back e.m.f. in a motor could not be greater than the forward e.m.f. in a dynamo working under the same conditions as to speed and current. The secret of obtaining this increased e.m.f. in motors was, he believed, the employment of a relatively powerful armature.

Mr. Willans, speaking of the Admiralty temperature limit, said that in testing the combined efficiency of engines and direct driven dynamos they had, with machines that run cool, obtained 84 or 85 per cent. of the indicated horse-power available at the dynamo terminals. On the other hand, machines that get hot never yielded more than 70 per cent. Whilst agreeing with the Admiralty that the rise of temperature allowable should be small, he objected to the method of taking the temperature; this method he characterised as being more a test of the heat conductivity of the insulation and thermometer than of the temperature of the machine.

Professor Forbes said he could not accept Mr. Swinburne's statement that self-induction *prevents* waste of power, for all sparking is due to self-induction, and consequently it *causes* a waste of power. Another point about which he had grave doubts was the efficacy of the method of throttling cross induction. His own opinion was that such methods would tend to concentrate the lines about the trailing corners of each half of the partially divided pole piece, and to diminish them at the leading corners of each half. He also thought that by partly filling up the space at E a greater induction through the armature would be obtained. Referring to reversing pole pieces, he thought them ingenious, but open to considerable objection, and believed other and better means of preventing sparking would be devised. Coming to Mr. Esson's paper, he said the author's remarks, respecting the utility and accuracy of calculating the waste field, were directly opposed to his own opinion on the subject, and also to the experience of Mr. Ravenshaw. This point, he thought, gave a good instance of how some self-designated "practical men" object to spend the few hours necessary to calculate the waste field, and prefer spending a month's labour in making a machine, with all its attendant expense, in order to obtain experimentally results which could have been readily derived by calculation.

Mr. Mordey did not agree with Professor Forbes as to the result of reducing cross induction by the methods shown in Figs. 3 and 4 of Mr. Swinburne's paper; in fact, he considered the plan quite natural, and it was very effective in well-designed machines. He thought that subsidiary or reversing pole pieces would not be practical, and that sparking is generally due to overloading. A better plan of preventing sparking would be to utilise the additional length of armature which the pole pieces require for lengthening the main core, thereby reducing overloading.

Mr. Swinburne here pointed out that the devices were not to prevent sparking, but to reduce the back turns, thus diminishing or rendering unnecessary the series windings on machines for constant e.m.f.

Mr. Mordey (continuing) referred to "small air space dynamos," and said Mr. Swinburne was once a great advocate of such machines, as well as of "large output dynamos." However, as far as he was aware, no great progress had been made with either variety, for makers seem to have come back to machines having moderate air spaces and of moderate output. The Brush machine had been tried shunt wound, but it would not excite at small loads, and at large loads it flashed round. The supposition as to the cause of excessive heating of the trailing horn given in the paper was not satisfactory, for the same corner heats if the machine be run as a motor, only not quite so much. The effect is probably due to the magnetic tufts from the Pacinotti projections. In discussing methods of measuring temperature of machines, he said this was sometimes done by measuring the resistance of the armature when hot, but this was not to be relied upon, for, owing to expansion and consequent charge of coated resistance at the soldered joints, the resistance hot might be less than when cold.

Mr. Sayers questioned the accuracy of Mr. Swinburne's view of the action of coils short-circuited by the brushes shown, and thought the various statements were not consistent. One serious cause of sparking, which had not been referred to in either paper, was the want of accuracy in making all the sections and commutator bars exactly alike, and spacing them with rigorous exactness, round the armature. In his opinion nothing short of the accuracy obtained by engineers in cutting wheels would effectually overcome sparking. Neglect of such precaution causes variation in the non-sparking position, the result of which may sometimes be seen in some segments being marked whilst the others remain perfect.

Mr. Crompton said in making large machines difficulties presented themselves which were unimportant in small dynamos; for example, as pointed out in Mr. Swinburne's paper, the magnetic leakage across the internal cavity of Gramme armatures becomes serious. On the whole, he was inclined to agree with Mr. Swinburne's remarks on the disadvantages of Gramme as compared with drum armatures. Some doubt, he said, still exists as to the necessity of insulating the driving hubs of drum armatures from the shaft; in his opinion it was not necessary. The question as to what material should be used for transmitting the driving strain from the shaft to the armature required careful consideration; he himself found aluminium bronze and delta metal fairly satisfactory, for they combine good mechanical strength with high electrical resistance. Another point requiring particular attention was the subdivision of the armature conductors in machines for large currents. The heating of the conductors in "bar armatures" due to Foucault currents may be considerable, but by subdividing the bars into sections, and twisting them through half a turn, he had succeeded in reducing this effect to about half its former value. Referring to Mr. Mordey's statement about the lessened resistance of hot armatures, he said he had never observed such an effect, and thought the joints in machines exhibiting such peculiarities must have been defective. In conclusion, Mr. Crompton replied to Mr. Esson's remarks respecting his dynamo, by saying that this was the first machine in which the design had been influenced by the idea of magnetic resistance; and he was glad to see that its armature was the father of all modern ones of the Gramme type. In support of this he pointed out that the ratio of radial depth to diameter was one to five, a proportion now almost universally adopted.

The discussion was then adjourned to the 20th inst.

THE PHYSICAL SOCIETY.

At a meeting of the Physical Society, held on the 7th inst., Dr. S. P. Thompson described Bertrand's refractometer, and exhibited the capabilities of the instrument before the Society. Its action depends on total reflection. The refractometer consists of a hemisphere of glass, about 8 mm. diameter, set at the end of a tube, the plane face being outwards and inclined at about 30 deg. with the axis. One side of the convex surface of the hemisphere is illuminated through a piece of ground glass, set about perpendicular to the plane face. The hemisphere is viewed through an eye-piece focussed on a scale divided to tenths of millemetres placed within the tube. The instrument is particularly useful for mineralogical specimens and liquids. The procedure in the latter case is to smear a film of the liquid over the plane face of the hemisphere, and by looking through the eye-piece determine the scale reading of the line which separates the light and darker portions of the field. A reference to a calibration table gives the refractive index. In experimenting with solids, a thin film of a very dense liquid (supplied with the instrument) is placed between the specimen and the glass, and the procedure is then as above. The refractive index of opaque solids can be determined in this way. In using the instrument for minerals great care must be taken not to scratch the glass. The handiness of the refractometer and its perfect portability (its dimensions being about 5 cm. long by $2\frac{1}{2}$ cm. diameter) are great recommendations.

In the discussion which followed, Mr. Blakesley asked to what accuracy the scale could be read, and whether the sensitiveness of the instrument was at all comparable with that of other methods; and Professor Dunstan inquired if it could be used with volatile liquids. In reply, Dr. Thompson said that with non-homogeneous light the scale could be read to one division, but with a sodium flame one-tenth of a division could be estimated. For volatile liquids a drop may be used instead of a film, or the evaporation of a thick film may be pre-retarded by a cover glass.

Professor Dunstan then described an apparatus for distilling mercury in a vacuum, devised by himself and W. Dymond, and showed the working of the arrangement. It consists of a 3 mm. soft glass tube, rather more than a metre long, having an oblate spheroidal bulb blown at the upper end. The bulb is placed over a ring burner. At the top of the bulb, a tube of 1·5 mm. diameter is attached, and this passes outside the bulb and descends close to the larger tube. The part of the smaller or fall tube just below the bulb is enlarged so as to form a condensation chamber, and the lower part serves as a Sprengel tube. A conical reservoir, containing the mercury to be distilled, is in flexible connection with the lower end of the large tube, as in Clark's well-known apparatus. The advantages claimed for the new apparatus are, its relative shortness and portability, the small quantity remaining undistilled, and its non-liability to damage derangement if left unsupplied with mercury. To ensure satisfactory working a constant pressure of gas is necessary, and this is obtained by inserting a Sugg's dry governor in the supply pipe. During distillation, peculiar green flashes are seen within the condensation chamber, and these are intensified by bringing it near an electric machine in action. The apparatus also serves well to show the character of an electric discharge through mercury vapour, for the mercury in the two tubes may be used as electrodes.

After the reading of the paper, Professor Thompson said he devised a simple form of distilling apparatus some time ago which answered fairly well, and could be made by any amateur glass worker. It consisted of a double barometer, one leg of which was of small bore, so as to act as a Sprengel tube. The rising part of the bend at the top of the larger tube was expanded, and served as the evaporating chamber, below which a burner was

Digitized by Google

placed. The President asked why Clark's apparatus is made so lengthy. In reply to this question, Mr. Boys said that as the fall tube goes down within the rising one, the mercury near the top of the latter is heated by the condensing mercury (thus economising gas), and hence condensation does not take place until the vapour has passed a considerable distance down the fall tube.

Professor S. U. Pickering then read a paper on "The Theory of Osmotic Pressure and its Bearing on the Nature of Solution." The author said that considerable doubt exists as to the accuracy of the premises on which the theory is based, and if the theory is to be regarded as true, and not merely a rough working hypothesis, the following conditions must be fulfilled by weak solutions: (1) The molecular depression of the freezing point must be independent of the nature of the dissolved substance; (2) any deviations from (1) must be in the direction indicated by the theory; (3) the depression must be independent of the nature of solvent; (4) the depression must be independent of the amount of solvent (all solutions being weak); (5) the deviations, with strong solutions, should be in the theoretical direction, and (6) they should be regular. Prof. Pickering proceeded to show that experiments, instead of confirming the above statements, disproves them all. As regards (1), without counting abnormally low (half) values, Raoult's results show variations of 60, 40, 30, &c. per cent. in different cases, and the author quoted other values where the variations were 500, 260, 230, &c. per cent. These variations, he considered, were too great to be explained by the fact of the solutions used being three or four times too strong. Referring to (2), he said that low values are explained by the polymerisation of the dissolved molecules, high values by their dissociation into ions. He then argued that there are no abnormally high values, for the view that such exist and that they are explainable by dissociation involves the following conclusions:—(*a*) That the more stable a substance is, the more easily is it dissociated; (*b*) that solution dissociates molecules which we know can exist undissociated as gases; (*c*) that water must consist of $1\frac{1}{2}$ H_2O and the atomic theory is wrong; (*d*) that energy can be created, and therefore the theory of its conservation is untenable. With respect to (3) it was pointed out that in many instances the same dissolved substance gives the full depression with one solvent, and half depression with another. Cases were quoted where the depression produced by the same dissolved body in different solvents showed variations of 36,000, 21,000, and 28,000 per cent. In discussing (4), the author said that, even with solutions weaker than that corresponding to a gas, the law is not fulfilled. Taking the case of sulphuric acid (the only one at present fully investigated), the variations amount to 40 per cent., or about 28 times the experimental error. With reference to (5) it was stated that with strong solutions the molecular depression should become smaller, but in every known case (nine were quoted) it becomes larger, the increase in one instance being 3,200 per cent. As regards (6), all experimental data available, especially those relating to sulphuric acid, show that the deviations are neither regular nor always in the same direction.

M. T. H. Blakesley said he was greatly interested with Professor Pickering's paper, for some time ago he was induced to make experiments on the volume of salts in solution by reading Joule's papers on that subject. Some of the results confirmed, but others did not agree with, Joule's theory that the molecular volume in solution was a whole number. If this theory was true, then (he said) it would be possible to predetermine the density of solutions, and from the measured density of any known solution we could determine the water of crystallisation of the salt from the formula

$$n = (A/H_2O + x)[1 - (D - 1)\,W/w]/D$$

where W and w are the masses of the water and salt respectively, D the density of the solution relative to water at the same temperature, A the molecular weight of the dehydrated portion of the salt, x the number of molecules of water, and n the molecular volume of the salt in solution, the two latter being whole numbers.

Notes.

PATENTS IN QUEENSLAND.

We have recently received the first installation of a series of publications containing the complete register and illustrated abridgments of the patents granted in Queensland from 1860 to 1884. A patent law was first established in that colony in the former year, but it was far from being perfect, and it continued in that state until 1884, when the improved law came into force. During those twenty-four years no official abridgments of patents were made, and these arrears of work have devolved upon the Patent Office during the last few years. Great difficulties were in the way of the successful completion of the undertaking, but the authorities have managed to turn out some very satisfactory abstracts and illustrations.

RAILWAY CONSTRUCTION IN THE UNITED STATES.

According to the *Engineering News*, railway construction in the United States will, during the present year, show more activity than in any year since 1887. A summary shows 5,038 miles partially completed, 7,041 surveyed or under survey, and 2,831 miles to be surveyed—a total of 14,910 miles. Canada has a total of 2,118 miles.

A NEW PHOSPHORUS COMPOUND.

In the course of a lecture at the Royal Institution on Friday last, on "The Glow of Phosphorus," Professor T. E. Thorpe mentioned that, in experimenting on the slow combustion of phosphorus, he had recently discovered a new compound whose composition is represented by the formula P_4O_6. This body exists as acicular crystals, which melt on the application of the hand, and it can be made to glow in the same way and under the same conditions as phosphorus itself. It readily burns in oxygen and chlorine, and its action on ethyl alcohol is to form the hitherto unknown compound $POH(C_2H_5O)_2$. It is quite probable that further researches as to its properties will reveal some interesting facts about the glow of phosphorus.

MINING IN CHILI.

Some time back a new mining law was passed in Chili, and a full translation thereof has now been published by the Foreign Office. The effect of the law will be to greatly encourage the mining industries, and this should open up an increased market for the makers of mining plant in this country. Chili possesses a very large number of gold mines, but these were abandoned when copper mining was taken to, and also because at a certain depth they all run into iron pyrites, and with the primitive method of extraction then existing 60 per cent. of the gold was lost in washing the pyrites. The people at present working gold mines are poor, and without the necessary means of working on a scale adequate to the requirements of the industry, and for introducing new and more perfect methods of gold extraction. The remedy suggested is that English syndicates should be formed for taking up mining properties in Chili, and to exploit them with modern machinery.

THE PROPOSED UNDERGROUND RAILWAY IN EDINBURGH.

Notwithstanding the decided opposition which is offered to the proposed underground railway in Edinburgh by the Town Council, there is a considerable feeling in favour of the proposals of the Caledonian Railway Company. The Trades Council has strongly supported them, and expressed the opinion that if carried out they would promote the prosperity of Edinburgh and Leith. Sir James Gowans, the Dean of Guild of the City, supports them on the same grounds, and moreover thinks that, if certain precautions were taken, the amenity of the city would be enhanced rather than depreciated. Recent events have shown the correctness of the opinion which we expressed when writing of the subject a few weeks ago. (See *Industries* of the 28th ult.). We said that "if the North British and the Caledonian Railway Companies, instead of attending only to their own interests, would unite, and bring forward a scheme which, while respecting the rights of owners and of the community, also met the convenience of the general public, it would receive the support of all concerned, and would in the end lead to their own advantage."

TWENTY-FIFTH ANNIVERSARY OF THE BENZENE THEORY.

On March 11th, in Berlin, was held a meeting to celebrate the twenty-fifth anniversary of the benzene theory as advanced in 1865 by Professor Kekulé, of Bonn University. Since this date rapid strides have been made in organic chemistry mainly by its aid, and as a result of this progress in the pure science many important technical industries have arisen, which, by the manufacture of coal-tar colours, pharmaceutical and medicinal products, disinfectants and antiseptics, have wrought immense changes in the health, comfort, and progress of mankind. At the meeting the secretary of the London Chemical Society presented the following address from the Society:—"The President and Council of the Chemical Society, on behalf of British chemists, desire to offer to Professor August Kekulé their warmest congratulations on the occasion of the twenty-fifth anniversary of the promulgation of his theory of the constitution of aromatic compounds. The influence which the felicitous conception of benzene as a closed chain has had on the development of chemical theory, the impetus which it has imparted to the intricate problems of isomerism among the derivatives of this and similar compounds, and the guidance which it has afforded in an industry of such importance and magnitude as that of the coal-tar colours, is universally recognised; and it is with special pleasure that the countrymen of Faraday, the discoverer of benzene, recount these benefits while paying honour to their author. This theory found the chemistry of even the immediate derivatives of benzene an almost untilled field. It has transformed it into a fertile province, to which have been annexed regions the very existence of which was unknown. May it long be permitted to Professor Kekulé, whose work has been so full of suggestion and inspiration, to remain witness to the benefits which continue to flow from his fruitful generalisation."

PRODUCTION OF PIG IRON IN THE UNITED STATES.

The production of pig iron in the United States of America is making rapid progress. During 1888 the output was about 6,000,000 tons, while for last year, although the exact figures have not yet been published, it is estimated at 7,600,000, being an increase of nearly 13 per cent.

A LARGE SALT FIELD.

At the annual meeting of the Stockton-on-Tees Chamber of Commerce the President stated that the Teeside salt field covered an area of eleven square miles, averaging 70ft. in thickness, although in some places it was as thick as 100ft. Each acre contained about 200,000 tons of salt, and the district contained enough to supply the whole world for 800 years.

THE INDUSTRIAL DEVELOPMENT OF THE SOUTHERN STATES OF AMERICA.

The difference in the industrial position of the Northern and Southern States of America has always constituted one of the greatest difficulties in arranging the policy of the United States of America. In fact, it may be said that this difficulty was as great a factor in causing the war between the North and the South as the slave question. In his recent message to Congress, the President pointed out the advisability of developing the industrial resources of the Southern States. From recent reports it seems as if that development were taking place with rapid strides. Particular attention is being paid to the improvement of the facilities for internal and external communication, and especially to the navigation of the rivers and harbours. Considerable quantities of coal are now being exported, while a large importation of Cuban or Spanish iron ore has taken place, for use in making steel from native ore, is anticipated.

FOREIGN TRADE OF JAPAN IN 1889.

It will be some time before complete reports are published of the foreign trade of Japan during 1889, but a short summary has been issued, some of the items of which may in the meantime be mentioned. The total trade excluding exports and imports of specie, amounted to 136,163,459 dollars, against 131,160,739 last year, showing an increase of over five million dollars, the greater part of which has taken place in the exports, for the imports were almost stationary. Yokohama, of course, takes the first place, with a total trade of 76,183,046 dollars, the imports showing a decrease of nearly two-and-a-half million dollars, and the exports an increase of about a million dollars. In Kobe (Hiogo-Ozaka) the total was 49,759,332 dollars, being an increase of over four million dollars. This increase is largely due to the improved railway facilities which now connect Kobe with the interior and open up the country for trade. The trade of Nagasaki is about ten million dollars, while that of Hakodate is under one million. The foreign trade of Japan for last year does not show very much of an increase, but it ought to be remembered that during the previous five years the increase was very great, and it is satisfactory to find that the total amount has been maintained.

APPLICATIONS FOR PATENTS.

(The names in italics within parentheses are those of Communicators of Inventions.)

ENGINEERING.

3rd March, 1890.

3321. Jewiss, A. ..... Sewing machines.
3324. Hoey, D. G. ..... Apparatus for ventilating.
3326. Anderson, A. ..... Sewing machines (*Singer*).
3330. Fisher, T. ..... Screw propellers.
3336. Bibby, T. ..... Saws.
3341. Melvin, A. M. ..... Hydraulic engines.
3343. Fletcher, Brown, & Ure Brick and pottery kilns.
3344. Morgan, D. J. ..... Furnace grates.
3345. Ives & Barker ..... Lifting and lowering bridges, viaducts, &c.
3346. Barnett, F. ..... Low level bridges.
3347. Sheppard & Rispin ..... Couplings for railway carriages.
3348. Walker & Stephenson (trading as John Perry) ..... Vices.
3349. Taylor, J. ..... Removing sand from river beds, &c.
3356. Jones, W. J. ..... Oil cups.
3359. Cutlan, F. ..... Machines for attaching heels.
3363. Heucken, C. ..... Coke ovens.
3369. Cammell, G. H. ..... Welding metals.
3370. Van Gülpen, M ..... Cigar-bunching machines.
3383. Johnstone, J. F. ..... Drying machines.
3385. Tafel, P. A. ..... Separation of iron from grain.

4th March, 1890.

3386. Ball, A. F. ..... Calculating machines.
3394. Brown, A. F. G. ..... Metallic packing.
3395. Morgan, D. J. ..... Steam gauges.
3396. Wade, J. ..... Self-feeding motor.
3400. Allison, H. J. ..... Rock drilling machine (*Githens*).
3402. Wilson & Welsh ..... Protecting locomotive engines and trains from damage by collisions.
3404. Legge, J. ..... Lever rim locks.
3405. Salmon, H. ..... Automatic registering machines.
3414. Légé & Job ..... Air meters.
3415. Armour & Armour ..... Retorts for distilling shale.
3420. Whytlaw & McLaren ..... Looms.
3423. Summerskill, C. W. ..... Compound valve.
3428. Edwards, D., Jun. ..... Lifts.
3431. Naylor & Williams ..... Moulding bricks.
3434. Mayer, L. J. ..... Extinguishing fire.
3435. Cousins & Clarke ..... Machinery for bending cranks.
3438. Boult, A. J. ..... Tool-grinding machines (*Benton & Waldo*).
3442. Pegg, S. J. ..... Stone-breaking machines.
3447. Caspar, H. ..... Sleeping cars.
3449. Shaw, D. D. ..... Car couplings.
3451. Naylor, W. H. ..... Machinery for twisting cords.
3454. Trask, C. H. ..... Milling machines.
3456. Billings, J. D. ..... Machines for the manufacture of horse shoes.
3457. Lake, H. H. ..... Machines for lasting boots (*Copeland*).
3462. Von Solemacher, Baron A. ..... Manufacture of bricks.
3466. Justice, P. M. ..... Wood working machines (*Thompson*).
3468. Horsey, J. G. ..... Chairs for railways.
3469. Denne & Denne ..... Sewing machines.
3473. Malam, W. ..... Steam generators.
3474. Kiddier, Kiddier, & Kiddier ..... Rotary knitting machines.
3476. See, H. ..... Pistons.
3477. See, H. ..... Horizontal pistons.
3478. Graham, J., Jun., & Graves ..... Hydraulic travelling cranes.
3479. Sharpe, F. S. ..... Sewing machines.
3483. Burdom, L. L. ..... Seamless compound ingot
3485. Brotherhood, P. ..... Slide valves.
3486. Winburn, W. ..... Ball valves.
3487. Lake, H. H. ..... Smoke consuming furnaces (*Walker*).

5th March, 1890.

3488. Ledward, T. ..... Ejector condensers.
3497. Hampson & Bagnall ... Links of chains.
3498. Hunter & Machie ..... Winding yarn.
3500. Sayer, R. C. ..... Hoists and elevators.
3504. Fox, S. ..... Dies.
3506. Pickering, J. ..... Increasing the draught of furnaces.
3507. Sparkes, S. H. ..... Machinery for sectional warping.
3511. Campbell, H. ..... Machinery for making nails.
3514. Lloyd & Hemming ..... Draining tramways.
3516. Thompson, W. P. ..... Railway couplings (*Ford & Whitworth*).
3525. Schönheyder, W. A. G. Sight feed lubricator.
3531. McDougall, A. ..... Construction of vessels.
3535. Borland, Wood, & Carter ..... Injectors.
3536. Jones, W. ..... Sewing machines.

6th March, 1890.

3543. Elwell, T. ..... Steam boilers.
3549. Sabel, F. W. ..... Engraving machines.
3550. Johnston, D. ..... Lowering ships' boats, &c.
3552. Auld, W. ..... Furnaces.
3554. Elsworth, J. F. ..... Hydraulic valves.
3568. Mackenzie, J. ..... Propelling vessels.
3573. Parsons, E. ..... Railway chairs.
3575. Hayes, J. ..... Light steel railway.
3581. Granotier, P. ..... Constant water level in steam boilers.
3583. Lindner, R. ..... Starting gear for compound locomotives.
3587. Kreyczik & Kapri ..... Operating tramways.
3588. Horn, W. W. ..... Metallic railway cross-tie and rail-fastening (*Wiegand*).
3590. Hughes, Rigby, & Pirrie Valve for hydraulic elevators.
3591. Paddon, E. F. ..... Furnaces.
3593. Marchant, S. W., Jun. Apparatus for the manufacture of paper.
3594. Redfern, G. F. ..... Nut locks (*Barney*).
3595. Stanley, R. ..... Boring machines.
3599. Boult, A. J. ..... Metal cylinders (*Coas*).
3603. Pifre, A. ..... Hydraulic lifts.

7th March, 1890.

3614. Holgate, F. ..... Doors of lifts.
3615. Milnes & Birks ..... Round or conical shot and shell.
3621. De Macedo, J. A. ..... Tram rails.
3626. Norton & Hinchliffe ... Apparatus for dyeing warps.
3627. Arnall & Peirce ..... Hydraulic lifts, &c.
3632. Taylor, G. ..... Loading and discharging vessels, &c.
3634. Earnshaw, A. ..... Planing machines
3637. Walker & Carey ..... Lifts.
3642. Bawden, R. ..... Ploughs.
3646. Blaiberg & Marson ..... Drill braces, &c.
3651. Teasdale-Buckell, G. T. Printing apparatus.
3659. Galloway & Beckwith Slide valves.
3665. Papendick, R. E. ..... Fitting pulleys to shafts, &c.
3668. Foulds, R. ..... Circular shuttle box looms.
3674. Naumburg, S. J. ..... Railway switches.
3675-6-7. Lever, Holland, & Todd ..... Boiler furnaces.

8th March, 1890.

3678. Tosh, G. ..... Rolling mill machinery.
3679. Hulme, W., Jun., & Hulme Connecting pipes.
3681. Keith, J. ..... Hydraulic valves.
3688. Rothwell, Rothwell, & Collier ..... Picking motion of looms.
3696. Culpan, J. ..... Looms.
3699. Hetherington, J. M. ... Mules.
3700. MacLellan, J. A. ..... Stop valves.
3703. Norton & Hinchliffe ... Apparatus for dyeing hanks.
3704. Bremberg, A. ..... Rotary gun carriages.
3706. Phalp, O. ..... Automatic relief springs.

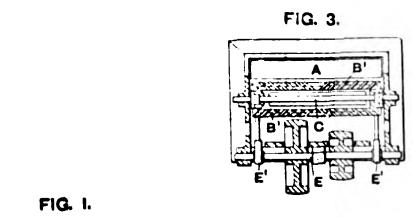
ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.

ENGINEERING.

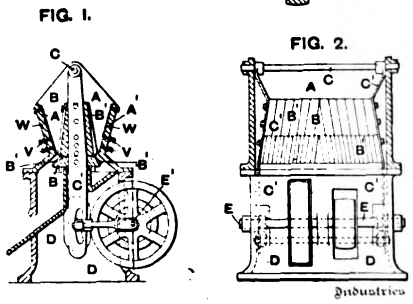
Mechanical Stokers.—*W. Leach, Accrington, Lancashire.*—The apparatus here described is intended to be worked in combination with the deflecting plate which is employed for distributing fuel into the furnace of a steam boiler as described in the specification of a previous patent, No. 16096 of 1887. According to this invention a tube is inserted in the front and at the top of the furnace, and a steam pipe made to communicate between it and the steam in the boiler. The outer end of the tube is open to the atmosphere, so in passing steam through it to the furnace air is drawn in with it. The air and steam thus passed into the furnace descend upon the smoke and force it down into contact with the fire, which consumes it, thus preventing its emission of dense smoke. By combining the smoke preventer with the mechanical stoker previously patented, the regulation of furnaces will be nearly automatic. Claim: In steam boiler furnaces the introduction of air and steam for consuming smoke in combination with a deflecting plate as described.—No. 9500. June 8th, 1889. 6*d*.

Scutchers.—*W. Hurst, Rochdale.*—This invention relates particularly to the gratings or grids which are placed between the beaters and the cages used in these machines, and the novelty consists in the arrangements by which the bars or grids of the gratings or grids may be altered in position such as to be in the most effective position. One method of carrying out this idea is to employ a grating or grid formed of bars or metal plates, and so arrange the alternate bars or plates that they may be raised or lowered by means of a cam or other suitable means. Another method is to secure the bars or plates in a cross-rail, which cross-rail and the bars secured to it may be raised or lowered by a cam. A third method is to employ a grating or grid formed of bars or plates, which are caused to approach towards or recede from one another as desired. The bars are mounted in suitable guides, and made to approach or recede from each other by means of a shaft or shafts formed with screw-threads of variable pitch. Or the bars or grids may be connected in the manner of parallel rulers. Three claims are made.—No. 6327. April 13th, 1889. 8*d*.

Spinning Rollers.—*E. de Pass, London.* (*G. Carbonnier, Pont St. Pierre, France.*)—The rollers made according to this invention do not slip upon the axle; they are cylindrical and without joints. The roller is made by glueing to an axle a facing of carded cotton, which is laid on in sheet form and then silicated. The silicate is applied in the form of silicate of soda, and at the same time the roller is rolled between other rollers to bring it to the thickness required. The silicate of soda serves as a varnish and agglomerate, but it may be substituted by any other suitable substance that would effect the same purpose. Claim: The improved covering for spinning rollers, characterised by the application of carded cotton, or other analogous material, glued or cemented on to the axis, then impregnated or treated with silicate of soda, or other like substances, producing the same effect as described.—No. 6352. April 13th, 1889. 4*d*.

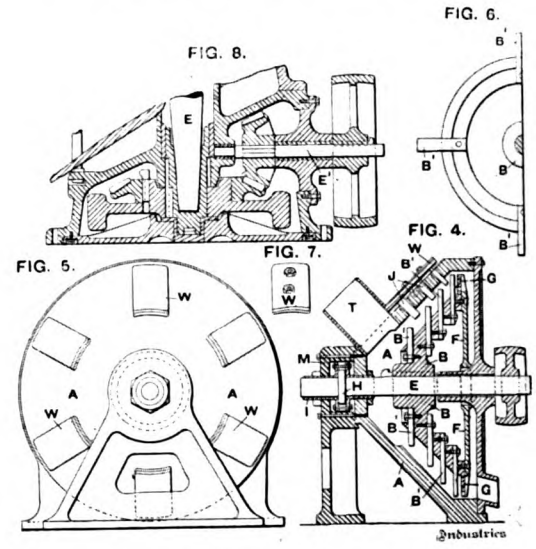


Tramway Points.—*J. Burrow & R. Johnson, Manchester.*—By this system the driver of a tramway car is enabled to guide the car in any desired direction without dismounting. A metal case is let into the ground, between the rails and at a short distance before the points. In this case is fitted a rocking lever, whose two arms extend upwards and project through openings and into grooves made in the lid of the case. The arms of the rocking lever are arranged so that when one projects into its groove the other is below. The rocking lever is connected by a bell-cranked lever and rods to the movable tongue of the points. On one of the axles of the car is a long boss provided with two arms, each arm carrying a small wheel. These arms are so mounted that the positions of the two small wheels correspond with the grooves in the top of the case. The long boss is provided with a third arm, which is connected by a rod to a controlling lever at the front of the car. By this controlling lever the driver can lower one or the other of the small wheels and cause it to pass along one of the grooves and operate the rocking lever. The rocking lever shifts the points, and the tram car passes in the required direction. Claim: The improved means for enabling the driver to actuate the points on a tramway without dismounting from the car, which consists principally of a rocking lever or scale beam, the arms of which project through grooves in the lid of a box sunk in the road between the tramway lines, the said rocking lever being connected to the movable tongue of the point; in combination with a corresponding rocking lever attached to the car, and fitted with wheels, which are adapted when depressed to run in the said grooves, such rocking lever attached to the car being so connected to a hand lever, within easy reach of the driver, that by moving such hand lever he can depress either wheel so as to act upon either arm of the first-named rocking lever, and thus move the tongue of the point, all being constructed and arranged as described.—No. 6303. April 13th, 1889. 11*d*.



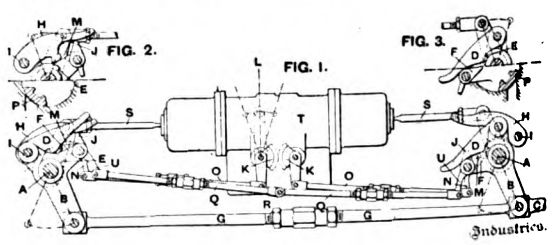
Pickers of Looms.—*T. Radcliffe, Halifax.*—This invention refers to a method of attaching picking straps to the pickers of looms for the purpose of reducing the friction upon the spindles when the shuttles strike the pickers. The picker is constructed with a projection or lug at the top of any suitable shape. The strap is passed through the picker, over the top, and the projection is passed through a slot in the strap, securely fastening it to the picker. The picker is formed with an ordinary scoop bottom with folded top. Claim: Pickers constructed with a projection at top, to which the picking strap is attached as described.—No. 6243. April 12th, 1889. 6*d*.

Fans or Blowers.—*A. Dougill, Leeds.*—Improvements are here introduced into the construction of the blades of fans and blowers with the object of rendering them more efficient. The vanes are formed of corrugated sheet iron. The corrugations may be made to run radially in the vanes, that is, at right angles to the axis of rotation; or they may be made to run longitudinally in the vanes or in a direction parallel to its axis; or lastly, they may be constructed diagonally across the blades, that is, in a screw or spiral direction around the axis of rotation. Claim: In rotary fans, ventilators, or blowers, the construction of the blades or vanes with corrugations as set forth.—No. 6248. April 12th, 1889. 6*d*.



Steam Ferry Boats.—*A. Brown, Renfrew.*—This invention describes an attachment to ferry boats for steadying them against the effect of a current, tide, or wash, and for holding them securely in position during the embarking or disembarking of vehicles and passengers. The appliance consists of a series of beams or spars, each one sliding in a socket pivoted to the side of the vessel, or otherwise connected to the vessel, to permit them being moved from a horizontal to a vertical position. When not in use the beams or spars lie horizontally against the side of the vessel, and serve the purpose of fenders, but to secure the vessel they are swung round to the vertical position and allowed to drop until they touch the bottom. The ends of the spars may be provided with spikes or otherwise suitably shod. Any suitable mechanism may be used to operate the spars, and be worked by steam, hydraulic, or other means. Three claims are made.—No. 6281. April 12th, 1889. 8*d*.

Pulverisers.—*G. Lowry, Barnsley, Yorkshire.*—Two separate machines are described in this specification; the one, as shown in Figs. 1, 2, and 3, is for coarsely crushing the material, and that shown in Figs. 4, 5, 6, 7, and 8 for pulverising the material to a very fine powder. In the crushing apparatus illustrated at Figs. 1, 2, and 3 A is the hopper or receiver, which is made of



oblong shape, with inclined sides A1. B is the crusher head, which is suspended in the hopper A by means of the shaft C and the side plates C1 C1. The plates C1 C1 extend down the ends of the crusher head B into the frame D, and are connected to the cranks or eccentrics E1 of the actuating shaft E, which thus imparts a pendulous motion to the crusher head B. The blades or moving tool B1 on the crusher head B are made by preference in two sections, so as to form a double set. The crusher head is tapered towards the top, so that the blades B1, which are set parallel with the ends of the crusher head, are spread out at the bottom. The blades B1 on the upper section are of greater pitch (say 4in. pitch) than the blades of the lower section (which may be, say, 2in. pitch), so as to break the material finer as it passes down. The hopper A is provided with adjustable side plates W, which can be set by the set screws V, so as to regulate the size of the opening between the crusher head B and the side plates W of the hopper A, and thereby regulate the size of the crushed material. Now with reference to Figs. 4, 5, 6, 7, and 8, in this case the receiver A is of a circular conical form, placed horizontally, the fixed tools or blades J, which are adjustable, are fixed by the plates W (see Fig. 7) which are placed round the shell of the receiver A, the tools passing through slots in the shell. The beater tools B1 are fitted to the head B, which is mounted on and driven by the shaft E. The tools J are stronger and coarser at the entrance part of the receiver than towards the extremity. The material or substance to be operated upon is fed in through the shoot T into the small end of the receiver A. The back of the crusher B is provided with an outlet plate or changeable screen F, having annular openings G as shown. The tail end of the shaft E is provided with a collar H, which runs in a screwed sleeve I, so that the shaft can be adjusted in the bearing M, and thereby the position of the crusher B and the tools B1 can be adjusted in relation to the tools J. Nine claims are made.—No. 1209. January 23rd, 1889. 8*d*.

Valve Gear.—*R. Middleton, Leeds.*—The valve gears referred to in this invention are of the form of trip gear valves in which the slide valves have cylindrical faces working in seats of corresponding curvature. The tripping mechanism is controlled by the governor, and improvements are made in the mechanism to cause it to act with greater promptness than heretofore. In Fig. 1 of the illustrations is shown a front elevation of the principal parts of the gearing. In the position shown the piston is at mid-stroke, the left-hand gear has just been tripped, and the right-hand gear is at the commencement of its stroke. In the Figs. 2 and 3 the valves are shown in section in the positions corresponding to those of the gear below. The valves P are worked by the rotary movement of the valve spindles A. Three armed levers B are fitted freely to the spindles A. The levers are coupled together by the rod G, and are rocked to and fro by an eccentric rod C. The other arms of the levers B support catches D and tripping toes J, M, and F. The toes J and M are part of the levers N, which are connected by the adjustable rods O to sector gear wheels K of the governor lever L. The toes F are part of the levers U, which are connected by the adjustable rods Q to a fixed pin R. Other catches H are supported upon stationary pins I. The valve spindles A are connected by the rods S to the dash pot T. The operation of the valve is as follows:—Referring to the right hand side of the gear in which the lever

B is in its extreme right hand position, the motion of the eccentric rod will now move B to the left. As B is moved to the left, the catch D engages with a catch E fixed to the valve spindle, and so shifts the valve over and opens it. As the valve is being shifted over, the toe F by the nature of its connections gradually assumes the position as shown in the left hand side of the gear and trips the catch D out of E. At the instant the catch D is tripped out of the catch E, the catch H falls into E and holds the valve in its open position, unless, as is shown in the left hand side of the gear, the toe J, which is actuated by the governor, holds the catch H out. When the speed of the engine is below the normal the valve is held by H in its open position until tripped by the toe J, actuated by the motion of the governor through the gear K; when the speed is above the normal, the toe M is caused by the action of the governor to lift the catch D, so that in the motion of the lever B to the left the valve is not moved. Claims: (1) The method of using double tripping devices on the steam inlet valves of a Corliss or other such valve gear, a part of the gear—actuated from a fixed centre—being used for bringing about the preliminary release and retention of the valve when it arrives in its "full open" position, whilst the other portion—actuated by the governor —is arranged to accomplish the final release and accompanying

Digitized by Google

closing of the steam port, for the purposes explained herein; (2) the valve gear with double tripping action, arranged, constructed, and operated, substantially as described and shown.—No. 4976. March 22nd, 1889. 8*d.*

STEAM ENGINES.—*C. Capeyron, Bordeaux, France.*—The invention is based upon a new application of a well-known geometrical principle, which is as follows: When a circle A (Fig. 1) rolls upon the inside of another circle F of double its radius, the two extremities of a diameter B C of the smaller circle will move upon diameters D E and G H of the larger or outer circle, the diameters being at right angles to each other. The centre I of the inner circle will also describe a circle X whose radius I L is equal to the radius of the inner circle. If, therefore, to one of the extremities B of a diameter of the inner circle is pivoted the rigid connecting rod of two opposite pistons, and to the other extremity C of the said diameter the connecting rod of two opposite pistons at right angles to the first, it follows that the alternating rectilineal movement of the pistons will transmit a circular movement to a crank whose radius I L is

FIG. 1.

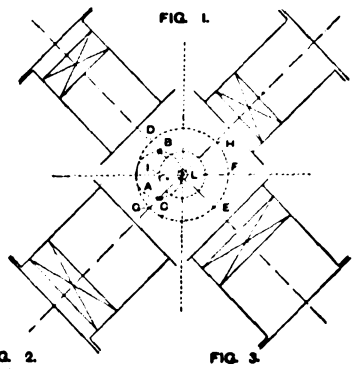


FIG. 2.

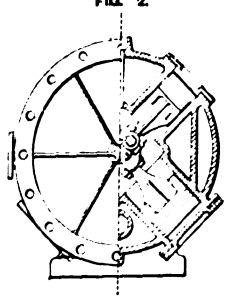

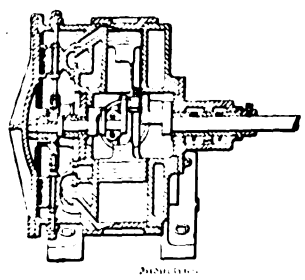

FIG. 3.

equal to that B I of the first circle A, and the centre L of which coincides with that of the second circle F. The improved engine constructed according to this invention is shown in Figs. 2 and 3. It comprises four fixed cylinders, the axes of which are at right angles to each other, and may be in the same plane, or in two parallel planes. By reason of the application of the geometrical principle above stated the stroke of the pistons will be equal to four times the radius of the crank. Claims: (1) The improvements hereinbefore described and represented in the figures of the accompanying drawing, substantially characterised by the arrangement of the fixed cylinders with perpendicular axes in the same plane or in different parallel planes; (2) the application of an intermediate crank enabling a rotary movement of the driving shaft to be obtained, the centre of which coincides with the point of intersection of the perpendicular axes of the cylinders; (3) the application of eccentrics to the movement of alternating slides.—No. 4570. March 15th, 1889. 8*d.*

BEARINGS FOR SHAFTS.—*E. W. G. Pomroi, London.*—In order to reduce the friction between axles and their bearings, the bearings are constructed according to this invention with a series of grooves cut longitudinally in their surfaces, and in these grooves are placed hardened steel rollers. The grooves are nearly cylindrical, but permit the rollers to project sufficiently to take the bearing of the shaft. Claims: (1) In axles and bearings the use of hardened steel rollers rotating in longitudinal grooves in the axles or bearings as described; (2) the improvements in axles and bearings as described.—No. 4571. March 15th, 1889. 6*d.*

STARTING GAS ENGINES.—*M. Partridge & R. H. Brutton, Yeoril, Somersetshire.*—A mechanical means is here described for starting gas engines. To the crank shaft of the engine is keyed a small ratchet wheel, by the side of which is mounted loosely upon the shaft a lever or hand crank. The hand crank carries a pawl which engages with the ratchet wheel in one direction, that is, the direction required to turn the shaft of the engine for starting; in the other direction the pawl passes freely over the teeth of the wheel. Thus the shaft may be turned by the hand crank until the engine has got well started, and then by letting go the crank its pawl will fall out of gear and the crank hang down stationary. Claim: In means or apparatus for starting gas and other engines or machines, a ratchet or other driving wheel fixed on the main or driving shaft, and a lever provided with a pawl or other driver, which, when the lever is raised, is capable of giving motion to the ratchet or other driving wheel, and when the lever is allowed to fall drops out of gear.—No. 6161. April 10th, 1889. 8*d.*

SIGNALLING TRAINS.—*S. B. Kincaid, Woodbridge, Suffolk.*—This appliance is for signalling trains in foggy or misty weather. To the under part or side of a locomotive is fitted a magazine for a number of short tubes. These tubes can be placed one at a time by the driver to hold down the end of a lever and keep closed a valve which operates a steam whistle. The tube is placed in position by the driver pulling a cord or some equally simple action. By the side of the rail is a second device consisting of a stiff post which can be raised or lowered simultaneously with the ordinary signals and by the same means. When in the raised position the post is so situated that as the engine passes the post it strikes the tube holding the whistle valve closed. The tube is thus smashed or bent and so dislodged, permitting the valve to open and blow the whistle, indicating danger. If the signal is not at danger the arm is lowered and no signal made. As one tube becomes broken another is caused to replace it from the magazine. Claim:—The use for signalling to the driver or other person on a moving train of a tube or bar of metal or other material fixed on the train in such a way as to operate the signal by the destruction of such tube or bar by its encountering a stationary cutter or breaker set when required so as to intercept the tube or bar, this tube or bar being so fixed that it cannot be struck out without being destroyed.—No. 20837. December 28th, 1889. 8*d.*

ROPE AND CHAIN GEARING.—*S. Eddington & J. E. Steerenson, Chelmsford.*—Bosses are fixed at certain intervals to the wire, rope, or chain. They are preferably made of a reel shape, and the rope passed through their holes. The bosses are secured in position by pins driven through them and the rope, and by filling up the remaining space of the holes, which are recessed, by metal such as lead. The pulleys for driving these belts are of the usual grooved form, with notches cut radially in their rims to receive the bosses or reels fixed to the rope. The bosses, instead of being made reel shape, may be made in halves of a disc form. The holes in the halves for admitting the rope are made to face each other when the halves are bolted together. The hole through the boss is thus made larger at its centre than at its outer parts. Where the boss is attached to the rope the rope is swelled by driving in a wedge. The swelled portion fits the enlarged part of the hole in the boss, and so the boss is retained in position upon the rope. Claims: (1) For transmitting power to machinery and for elevating or conveying goods, hauling carriages, trucks, and the like, or for dredging or other analogous purposes, the use or employment of bosses, cogs, or projecting blocks, fixed or fitted at intervals upon metallic ropes or cables, and engaging in recesses or wheels or pulleys as described; (2) the method of fixing such bosses, cogs, or projections as described; (3) the method of and means for transmitting power to machinery of various kinds as described.—No. 4,376. March 13th, 1889. 6*d.*

LOCOMOTIVE FURNACES.—*D. Clegg, Philadelphia, U.S.A.*—This device is constructed for the purpose of consuming the smoke and fine cinders that are otherwise discharged from the stack. The stack is divided longitudinally into three passages. The central passage leads to the smoke box of the engine, the two outer ones to the ashpit. The central passage of the stack is covered with a cap, to direct the smoke as it issues from it down into the passages leading to the ashpit. In order to drive the smoke down the passages into the ashpit the top of the stack is covered, and a flaring funnel-shaped opening made in the front near the top. When therefore the locomotive is in motion, the smoke, as it issues from the central passage, is directed down into the ashpit passages, and then driven down by a draught of air entering the funnel-shaped mouth. The smoke and fine cinders, with the draught of air thus driven down, pass through the bars of the furnace and are consumed, the larger cinders remaining in the bottom of the ashpit. Claims: (1) The combination of the combustion chamber and ashpit with the smoke stack at the upper end, and having communicating up and down flues with a deflecting hood and a valved inlet opening in the down flue; (2) the combination of the smoke stack provided with up and down flues, the deflecting hood, the head having an air inlet opening communicating with the down flues, and a valved opening in the upper portion of the said head, and mechanism for operating the valve from the cab of the engine; (3) the combination of the smoke stack having up and down flues, with openings in the said flues, and slats in each of said openings for directing air into the stack and creating a draught in the down flues for carrying the smoke to the ashpit; (4) the combination of the stack having up and down flues, openings in said down flues, with pivoted slats in said openings, said slats being controlled from the cab of the engine so as to regulate the draught: (5) the combination of the smoke stack, the up and down flues therein, a valved opening in the top of said stack, and openings in the down flues, with pivoted slats therein, a rod connected to the slats and to the valve rod, said rod being connected to a lever in the cab, so that on the operation of said lever the slats and valve will be operated simultaneously.—No. 19001. November 26th, 1889. 8*d.*

SHAPING BOLTS AND NUTS.—*O. Koch, Germany.*—This machine is intended for shaping a number of bolt heads or nuts simultaneously. In the accompanying illustrations Fig. 1 is a right hand side elevation, Fig. 2 a plan, Fig. 3 a cross section, Fig. 4 a left hand section, and Figs. 5 to 11 details. The machine has cutters B, one to each of the bolt heads being shaped; thus, in the machine shown there are six. The cutters B are mounted upon a slide A which receives motion from a crank M in the usual

FIG. 1.

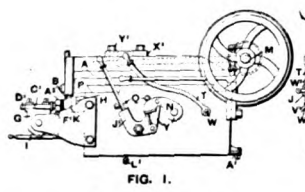

FIG. 3.

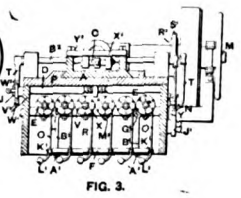

FIG. 2.

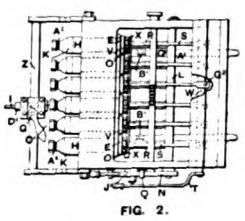

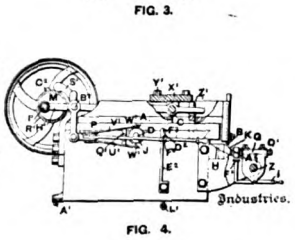

FIG. 4.

manner of shaping machines. The slide A is mounted upon a second slide P, which has a lateral motion sufficient to move the tool over the face of one bolt. Motion is given to the slide P by the screw spindle D which is revolved by the motion of the oscillating shaft B^2 transferred through the ratchet wheel J and spring pawls V^1, U^1 (Fig. 4), whose actions are reversible by the lever D^2 and spring stop E^2. The connecting rod H^1 of the slide A does not partake of the lateral motion due to the slide P, but is retained in position by the fork Z^1 and slides upon a cross-bar C, by which it is connected to the slide A. For shaping bolt heads the bolts are placed in the sleeves H under the cutters B. On each of the sleeves is a head K which receives a conical spring sleeve E^1 (Figs. 6, 7, 8, and 9). The bolt is placed in the sleeve E^1, as shown in Fig. 7, and the head of the bolt is pressed home, so that the sleeve E^1 grips the bolt firmly. For inserting the bolt in a proper position and driving it home, a small appliance G is provided, worked by the levers I and C^1, and sliding upon the bar Z. The part F^1 is brought to bear upon a face of the bolt head, whilst the pusher D^1 forces the bolt home. For turning the bolts

FIG. 5.

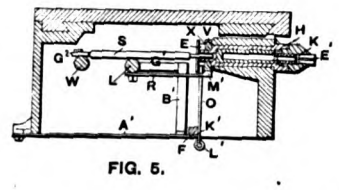

FIG. 6.

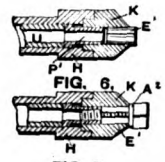

FIG. 7.

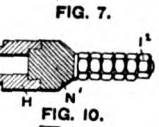

FIG. 8.

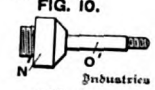

FIG. 9.

FIG. 10.

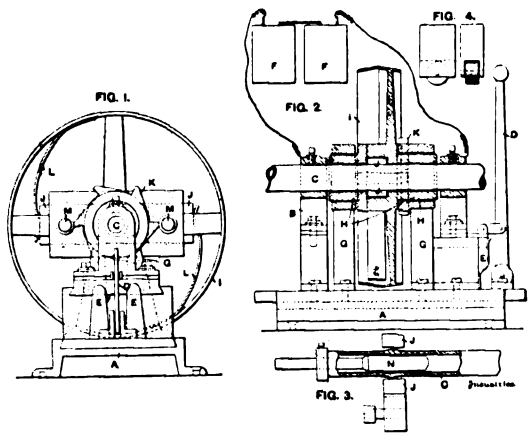
FIG. 11.

upon their axes, small division plates or discs E are fixed to the sleeves H, and revolved through one sixth of a revolution by the lever J^1 situated at the side of the machine. By moving the lever J^1 to and fro between the stops Q, the stops R are removed from the disc E, and the discs revolved by the pawls O and ratchet wheels X. The bolts are discharged simultaneously from the machine by forcing out the sleeves U by the rods S, to which motion is imparted by the shaft W and lever T. When shaping nuts, they are fixed to the machine by mandrils as illustrated in the Figs. 10 and 11. Five claims are made for this machine.—No. 18264. November 15th, 1889. 8*d.*

CARDING FLATS.—*E. W. Wrigley & Robert Patterson, Oldham.*—This invention relates to an improved means of more effectually protecting and supporting the carding wires at the edge of the card filleting forming the flat, and in that part generally named the heel of the flat. In performing this invention the length of the wires is reduced all along at this edge, and to the extent of about an eighth of an inch more or less in width, or wires of reduced length are employed, or a solid strip of metal is applied of about the same depth, riveted or otherwise secured in the same position. It is found that this means of supporting the edge of the card filleting also gives a straighter and more parallel edge to the carding wires than has been hitherto practicable. Claim: Improvements in carding engines as described.—No. 6485. February 15th, 1889. 6*d.*

ELECTRICITY.

SECONDARY BATTERY PLATES.—*W. L. Wise, London.* (*The Gibson Electric Company of Europe, Paris.*)—According to this invention a plate is constructed by striking out raised loops from the surface of a sheet of lead, or by casting similar loops on it. The active material extends under these raised loops, and becomes firmly united with the plate. The plate is preferably prepared with a raised rim round its edge of a height approximately equal to the thickness of the active material, and the loops are made of about the same height as the rim. Claims: (1) A storage battery plate, consisting of a sheet of metal, having portions thereof raised above its surface in the form of loops; (2) a storage battery plate, consisting of a sheet of metal, having loops raised from its surface and active material covering the surface of said plate and extending under the loops; and (3) referring to the drawings of specification.—No. 2472. February 12th, 1889. 8*d.*

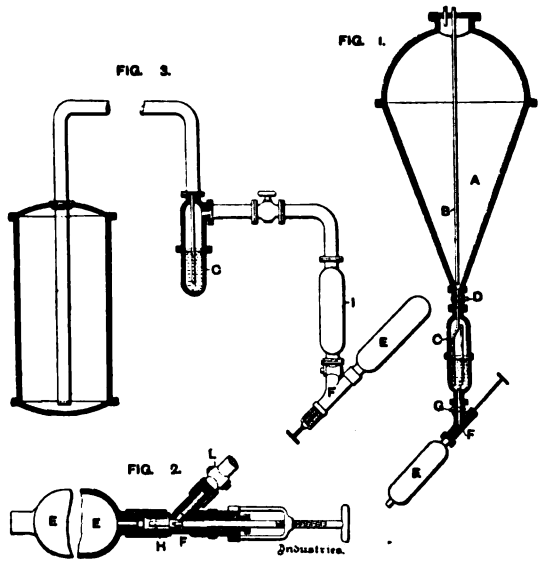


INSULATORS.—*C. V. Boys, London.*—The insulators are made by melting quartz or materials that are very largely composed of silica with the oxy-hydrogen flame or by the heat of the electric arc or by heat generated in infusible conducting rods or plates such as the carbons used for electric lighting, and when it is in the plastic condition working it into rods or pieces of any desired shape much as glass is worked, the treatment being slightly modified on account of the high melting point of quartz. In melting quartz in small quantities it is held in the flame much as the glass blower holds glass. When melted in larger quantities it rests on a bed of clean sand or broken quartz and heated from above or by electricity passing through carbon rods buried in the material. The quartz is preserved as far as possible from contact with earthy materials. When melted it is drawn or blown into rods, tubes, or other desired forms or rolled or worked in moulds. Claims: (1) The making of rods, tubes, or pieces of other desired shape by melting quartz, sand, or other material that is largely composed of silica substantially as described; (2) making insulators of quartz that has been melted or material largely composed of silica.—No. 4849. March 20th, 1889. 4*d.*

TELEPHONE TRANSMITTERS.—*J. C. Goulding, Cardiff.*—The transmitter is so arranged that it can be placed temporarily at any desired height to suit the person using it. Claims: (1) The improvement in telephone transmitters, which consists of mounting the telephonic apparatus upon a carriage capable of being raised and lowered upon guide-ways and of being readily adjusted thereon at any desired height, the connecting wires being provided with sufficient slack to permit of such vertical movement; (2) a telephone transmitter, in which a carriage having the telephonic apparatus mounted thereon is adapted to slide vertically between parallel uprights, and to be held stationary in any position in its vertical path by a friction device capable of setting up a sufficient amount of friction between the sides and the opposing

Digitized by Google

surfaces of the uprights, substantially as described; and (3) referring particularly to the appliance as illustrated in the specification.—No. 11215. July 12th, 1889. 8*d*.



WELDING METAL BY ELECTRICITY.—*H. E. Fowler, New Haven, U.S.A.*—In this machine the weld is formed by working the joint without removing any of the metal. After the weld has been formed by pressing the ends of the work together, the bulged part is hammered or rolled down to the normal size of the work by revolving hammers or rollers. In the accompanying illustrations, Fig. 1 is an end elevation, Fig. 2 a part section upon the side elevation, and Figs. 3 and 4 show details. Upon the base A are supported insulated standards B, which hold the tube C or other work to be welded. The standards B are connected to the source of electricity F, and one of the standards is made movable upon a slide operated by the spring E and the lever D. Two second standards G are fixed to the base and support the hollow trunnions H of a driving pulley I. In the boss of the pulley I are formed guides for the sliding hammers J. As the

pulley I is revolved these hammers are caused to oscillate in their guides by the studs M and cam wheel K in conjunction with the springs L. The operation of the machine is as follows:—Two sections of pipe, rod, or bar are secured in the bearings of the standards B, with their ends in contact, and the current of electricity is passed along the wires to the pipe. When the abutting ends of the sections are sufficiently heated or fused, the movable standard, with its section of pipe, is forced against the other, thus upsetting the ends of the pipe, as shown in Fig. 3. The pulley carrying the hammers or rolls is then rotated around the work, and the blows or pressure delivered upon this upset portion by the hammers or rolls, as the case may be, spread the metal on both sides of the joint and form a secure weld without removing any of the metal raised by the upsetting. Where the machine is used to weld pipe, a mandrel N may be inserted to prevent unevenness on the interior. Three claims are made.—No. 19892. December 10th, 1889. 6*d*.

CHEMISTRY.

MANUFACTURE OF LIQUID CHLORINE.—*J. B. Hannay, Loch Long, Dumbarton.*—In certain metallurgical operations—such, for instance, as extracting gold from the ores containing it—chlorine is advantageously employed. It is, however, generally difficult to produce the chlorine upon the spot where it is required to be used, and a method of storing it for conveyance, such as the one here described, is necessary. In this invention the chlorine is stored in a liquid state in the following manner: Chlorine gas is produced by any of the known processes and passed into a vessel A (Fig. 1) containing water at a temperature a little above

freezing point. The gas flows into A by the pipe B, and as it bubbles up from the mouth of the pipe to the surface of the water some of the gas combines with water and forms crystals, which fall to the bottom of A. Attached to the bottom of A is a smaller vessel C containing sulphuric acid and communicating with the vessel A by the cock D. To the bottom of the vessel C is connected the storing vessel E and its sealing appliance F, communication between the storing vessel C and the storing vessel E being formed by the cock G. When a sufficient quantity of crystals have accumulated at the bottom of A by the passage of chlorine gas through it, it is sealed and gently heated. The crystallised chlorine is thus liquified, and remains at the bottom of the vessel whilst the water it contained separates and ascends. By this process pressure is produced in the vessel A, and when the cocks D, G are opened the chlorine is forced through the vessel C, and the sulphuric acid contained in it to the storing vessel E, in which it is sealed by a screw plug H, as shown in Fig. 2. By passing the liquid chlorine through sulphuric acid any water present in it is absorbed before it passes to the storing vessel. Fig. 3 shows a modified form of the apparatus fitted with a graduated glass vessel I to make the charge visible. Claims: (1) For storage and transport of liquified chlorine the use of a holder made of bare steel tube closed at the ends with an end boss provided with a screw plug substantially as described; (2) for producing liquified chlorine and charging holders therewith, the combination of the funnel-shaped vessel A, the water trap C, and the branched pipe F fitted with screwed spindle substantially as described.—No. 4037. March 7th, 1889. 8*d*.

EXTRACTION OF IRON.—*A. Hodgkinson, Jun., Talke, Staffordshire.*—This invention relates to the manufacture into blocks of the calcined and hitherto generally unused or wasted products of the various ironstone seams known in North Staffordshire as the Half Yard Mine, the Red Shag Mine, the Red Mine, the Bassey Mine, and Red Mine Shale, and the respective equivalents thereto in parts of the United Kingdom other than North Staffordshire. Those products are generally known as "small mine," and they include uncalcined pieces of stone or rock containing iron which may have been left in the rocks on the mine hearths after the puddle or furnace mine has been formed and removed from the mine hearth for smelting. By this process the "small mine" is pressed into blocks by means of hydraulic machinery. These blocks are then ground or crushed to a semi-plastic powdered or granulated condition. If the "small mine" is damp it will, when reduced as above, be sufficiently plastic, but if it is not damp sufficient water should be added to make it plastic. This semi-plastic stuff is moulded by any suitable means into bricks, and then dried in the open or by artificial heat. The bricks so formed are suitable for further reducing the iron substances contained in them by the usual methods adopted in blast puddling or other furnaces. Claim: The treatment of calcined products and "small mine" of the above-mentioned iron ores, ironstone mines, and shale singly, or when two or more are mixed together, or with any other iron ores, ironstone mines, or shales, or other matter, and the manufacture by means thereof of blocks for the production of iron substances as described.—No. 4537. March 15th, 1889. 4*d*.

PRODUCTION OF HOMOGENEOUS IRON.—*A. E. Barthel, London.*—By the following method, pure and homogeneous iron may be deposited of any desired form and thickness. The process is a wet galvanic one. The bath for producing deposits of iron according to this invention is prepared as follows:—In five litres of well or river water six hundred grammes of crystallised ferrous sulphate (copperas) are dissolved. In a second vessel a solution of two thousand four hundred grammes of carbonate of soda in also five litres of water is made and the two solutions are poured together into a larger vessel. This mixture produces a deposit or sediment of ferrous oxide. Concentrated sulphuric acid is now added in small quantities to this fluid until the above deposit has again dissolved and has taken a cloudy or muddy green colour. Pure water is then added until the two solutions become a volume of twenty litres. Blue litmus paper when dipped into this solution must change but very little and should take a deep red wine colour. Should it become red only carbonate of soda must be added until the proper colour is obtained. Red litmus paper must retain its colour. Into the bath above described the object is placed upon which an iron deposit is to be produced as for instance a plate for the production of sheet iron or any object with a smooth or relieved surface to obtain a corresponding smooth or relieved impression or deposit. Cylindrical objects are required to produce tubes. Leaden bullets or other leaden articles can in this way be coated with iron. Opposite to the article intended to be covered with the above mentioned iron coating the anode of about the same surface as the object to be treated is suspended This anode may consist of cast iron, wrought iron, steel, or iron ore. Both the cathode and anode are now connected with the corresponding wires of a dynamo or any hydro-galvanic battery, and thereby acted upon until the iron deposit has attained the desired thickness. The temperature of the bath ought to be at least as high as 14° Reaumur to obtain a satisfactory deposit. Surfaces and forms from which the precipitate or desired iron deposit is to be removed must be first carefully cleaned from all dirt, grease, and oxide, and then rubbed with graphite and cotton, and may be even slightly coated with cyanide of silver or any other metal foundation. Claims: (1) The production of chemically pure homogeneous iron by a wet galvanic process, forming a deposit upon cathodes in a bath, composed as described, of hydrated ferro-protoxide, employing pig iron, or wrought or cast iron, or steel or iron ores, as anodes; (2) the production of fixed and firmly connected undetachable deposits of chemically pure homogeneous iron upon metallic surfaces or objects of all descriptions in a bath composed as described of hydrated ferro-protoxide and previous thorough cleaning of the article to be coated, the objects when of lead being first thinly coated with any other metal; (3) a direct process for the production by a wet galvanic process of detachable or firmly connected deposits of chemically pure iron in any desired form and thickness, such iron being formed by the employment of a bath of ferro-protoxide as hereinbefore described, and by placing the objects to be treated (after they have been cleaned from dirt, grease, and oxide) in the said bath, with an anode of wrought or cast iron, or steel or iron ores, both anode and cathode being connected with the corresponding poles of a dynamo, hydro-electric battery, or any other source of electricity.—No. 5078. March 23rd, 1889. 6*d*.

MANUFACTURE OF COPPER.—*P. C. Gilchrist, London.*—The invention particularly relates to the purification of copper from arsenic, antimony, and tin. Certain of the operations in connection with the production of refined copper are conducted according to this invention in furnaces lined with shrunk dolomite, magnesia, or other base. These linings are not employed in all the stages of copper refining, but may be advantageously in the following: In the fusion of calcined coarse metal, in the roasting of the white or fine metal for the production of blister copper, and in the refining of copper from blister or bar copper. The operation of refining the coarse, white, blister, or other form of impure copper is performed either in a reverberatory furnace as at present used, or preferably in an open-hearth regenerative gas furnace or other convenient form of apparatus, in either case furnished with a basic or chrome lining. The charge of coarse, white metal, blister, or other impure copper is placed in the basic furnace and melted down in an oxidising atmosphere as at present. With the copper is charged some lime or limestone, and some copper slags rich in oxide may be added. When the bath is thoroughly molten successive additions of lime or fine limestone are made, and when necessary some copper slags rich in oxide, the object being to obtain the oxidation of the arsenic, antimony, and tin present, either by means of the atmospheric air or by means of the small amount of cuprous oxide which forms, and to combine and fix the impurities in the slag. The amount of lime or limestone to be used varies with the composition of the charge. The slag should not be very silicious; it is preferable always to keep the silica under 20 per cent., the best results being obtainable when silica is under 10 per cent. Claims: (1) The purification and treatment of cupriferous reguluses and mattes and copper in basic or neutrally lined vessels in the presence of a basic slag whereby a slag lower in copper oxide than has heretofore been usual is obtained with a correspondingly larger yield of metallic copper substantially as set forth; (2) the treatment of cupriferous reguluses or mattes and copper in basic lined furnaces for the removal of arsenic partly by combining it with lime in the slag in place of copper oxide as at present, and partly by volatilisation, substantially in the manner herein described.—No. 4882. March 20th, 1889. 6*d*.

MISCELLANEOUS.

SIGNALLING UPON STEAMSHIPS.—*R. R. Little, South Shields, J. Hall, Newcastle-on-Tyne, & T. Archer, Gateshead.*—The appliance here described is for the purpose of signalling between the engine and the captain's bridge to indicate that orders referring to the working of the engine have actually been carried into effect. Upon the propeller shaft or other shaft operated by the engine is fixed a projection which revolves with the shaft and strikes two tappets, so constructed that when the shaft moves in one direction one of the tappets is worked, and when revolving in the contrary direction the other is worked. The tappets, when moved, compress air pumps or air displacers which are connected by tubes to the captain's bridge. On the captain's bridge the tubes are made of glass and contain balls which rise and fall as the air in the tubes is alternately compressed and expanded by the tappets working the pumps. Thus the one or the other of the balls work according to the direction in which the engine is going, and as the balls make but one rise and fall in one revolution of the shaft the captain is able to see any alteration in speed or direction. Claims: (1) In apparatus of the kind hereinbefore referred to, the combination of a projection from the propeller shaft (or from a shaft driven therefrom) and a pair of tappets or levers and air forcing or drawing devices for operating a signal and acted upon by the said levers in accordance with the direction of rotation of the shaft as described; (2) in pneumatic apparatus for conveying signals directly from the engine to the captain's bridge or other place the combination with air forcing or drawing devices and tubes of balls, spigots, or the like moving in the said tubes to act as indicators as described.—No. 5495. March 30th, 1889. 8*d*.

SIGNALLING TRAINS.—*A. S. von Blendorf & C. Adler, Baden, Vienna.*—This invention consists in providing an adjustable obstacle between the rails, which is adapted to operate a suitable device on the train as the train passes. The obstacle between the rails is preferably a metal disc mounted upon a slide. This slide, and with it the disc, is constructed to move to and fro transversely between the rails by means of the mechanism that works the signals. Upon the locomotive or tank is suitably mounted a mechanical device consisting of a spring arm or lever. When the signal is brought to danger the obstacle is simultaneously brought to danger by the slide plate already mentioned, and as the train passes the obstacle it acts upon the spring arm or lever and operates an alarum, air-brake, or similar means for warning the driver or stopping the train. At the time of operating the alarum, &c, the spring lever also causes the disc to partly revolve and connect up the electric circuit actuating an alarum at the next station. Claim: In combination with a line signal, a disc carried in and capable of turning in bearings between the rails of the permanent way, and adapted to engage with a yielding or resilient pendant device, and as a consequence to operate an acoustic signal on the engine, or the throttle valve, the reversing gear, or the brake, as and for the purpose described.—No. 5632. April 2nd, 1889. 6*d*.

INDICATING STATIONS, &c.—*H. Brocklehurst & H. Constein, London.*—The apparatus is designed for use on railway platforms for the purpose of indicating the stations that a train will stop at during its journey. It is worked by a current of electricity. A number of apertures are made one above the other in a hollow column or box. Behind these apertures are arranged tablets having the names of the stations marked upon them in the order they are situated on the line to which the column refers. These tablets are hinged so that when they hang down they may be seen through the apertures, and the name of the station upon them indicated. Normally the tablets are held up out of view by small catches, which are controlled by electro-magnets. When the electromagnet of a tablet is vitalised the catch is drawn back and the tablet falls upon its hinge, and the name of the station marked upon it is exposed. The wires of these electro-magnets are connected up, and the current passed through them, by a series of switches. Each tablet may be actuated individually or the whole series collectively. Three claims are made.—No. 3683. March 1st, 1889. 8*d*.

Copies of the British specifications may be obtained on application to H. READER LACK, Esq., *Comptroller-General, Patent Office, Southampton Buildings, London, W.C. The published price must be remitted, together with a sum sufficient to cover postage, which may be reckoned at* ½*d. for every* 10*d. or fraction of* 10*d. Remittances exceeding one shilling must be made by Post Office Order.*

IMPROVED DRILLING MACHINES.

THE design of the machine shown in Fig. 1 is very simple. It will be seen that no overhead motion is required; that there are four changes of speed; and that, as the mitre wheels always run at the same rate, there is no more tendency to cause noise at the highest speed than at the lowest. Silent running is still further secured by one of the mitre wheels being of gun-metal. The pillar is turned, and the table can be adjusted to any desired height. These machines are well made. The spindles and shafts are all of steel, and the feed motion is hardened to resist wear. They are also easy to fix, and entirely self-contained.

Fig. 2 shows a hub drilling machine which is complete in itself. The hub is carried between the centres of two small headstocks, one of which carries the dividing plate. These headstocks are mounted upon a sliding bed, which can be moved sufficiently to bring either flange of the hub opposite to the drill, and suitable stops can be adjusted to bring the slide always to the same position. This slide has also an independent swivelling motion for giving the correct angle; this motion is also controlled by stops, so that when the machine is once set a boy can work it without fear of mistake. The division plates employed are compound, with two rows of divisions arranged round the circumference, and the dividing catch may be readily moved from one row to the other. The first row of divisions is used for drilling the left hand flange of the hub, and the second row for the right, or *vice versâ*, so that the spokes in each flange are always correctly spaced with reference to those in the other. Also it is not necessary to reverse the hub, or to remove it from the machine, until it is drilled in both flanges. The makers of these two machines are Messrs. Herbert & Hubbard, engineers, Coventry.

THE PROTECTION OF CHIMNEY SHAFTS FROM LIGHTNING.

BY C. MOLYNEUX AND J. M. WOOD.

IT is by no means uncommon, even in the present scientific age, to see tall chimneys in various parts of the country which are unprovided with lightning conductors. Can this be due to ignorance and thoughtlessness, or to the consideration of the question of expense; or again, to a disbelief in the efficiency of a conductor as a means of protection against injury by lightning? To one or other of the above reasons must be attributed such culpable neglect. On the other hand, many chimney shafts are so provided; but if examined it would be found that their conductors are not in an efficient condition. So long as the rod is visible and in its place it is taken for granted that it is ready to perform its function; its efficiency is assumed to be as good now as when it was first fixed, perhaps twenty years ago. Corrosion, however, may have destroyed the joints, and even severed in two the conductor; whilst the upper terminals may have entirely perished under the action of the gases and weather. So, too, at the lower extremity there may be no proper earth connection.

On account of its height a tall chimney is more liable to be struck than any other structure—excepting perhaps a church spire—and such an accident may be attended with disastrous results to life when the shaft is placed in close proximity to a factory full of workpeople. This contingency alone should be sufficient to call for some legislation for the compulsory provision of lightning conductors.

A flash of lightning has been described as the passage of an electric spark between two bodies oppositely electrified, and between which the difference of potential or electric pressure is sufficiently great to cause a breaking across of the air space or dielectric which separates them. The object of a lightning conductor is to facilitate the safe discharge of this spark from the clouds should it occur; but it has another and equally important function, its action being preventative as well as curative. It tends to prevent the occurrence of a flash—*i.e.*, of a disruptive discharge—by silently neutralising the conditions which determine such discharges in the neighbourhood of structures which it is proposed to protect. Such being the case, and prevention being better than cure, a lightning conductor should be so constructed as to have that end in view as well as that of safely conducting the discharge to earth; and both these results are obtained by the same means—viz., by increasing the number of terminal points—thus reducing the tension and enlarging the zone of protection. Nevertheless, experience shows that the occurrence of a flash cannot be prevented by the silent discharge of very numerous terminal points.

IMPROVED DRILLING MACHINES.

CONSTRUCTED BY MESSRS. HERBERT & HUBBARD, ENGINEERS, COVENTRY.

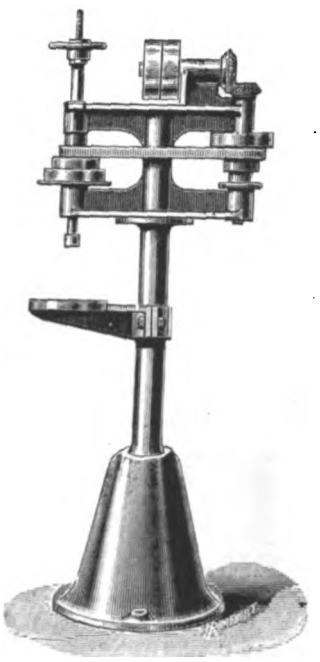

FIG. 1.

FIG. 2.

Such cases are attributed to the electrical energy stored up in the clouds being so great that no points are sufficient for the work of silently reducing the tension below the sparking point. Or, again, the electrical energy may be so rapidly generated or sparked from cloud to cloud that there is not time for the choice of the best path, and the nearest object is struck with apparently little discrimination. But under ordinary conditions of electrical disturbance, a path is created inductively beforehand; and a well-made lightning rod, if near that path, will become part of it, thus protecting the building to which it is attached. As a matter of fact it has been found in the course of many years' experience, both in Europe and America, as also in all parts of the world, that lightning conductors seldom fail to act the part expected of them. In this country the past experience of the postal telegraphs clearly points to the practical value of conductors. In the Navy no accident is stated to have occurred since 1872, whilst the rods attached to British lighthouses have failed on very few occasions only.

The following is a description of a good recognised form of conductor for chimney shafts. Starting with the sky end, points offer the best protection, but they need not be high spikes or tridents. The Lightning Rod Conference of 1881 expressed the opinion that a coronal or heavy band, with copper points about 1ft. in height at intervals of 2ft. throughout the circumference, would form the most useful and durable sky end for a conductor, and this advice has since been followed in many cases. Under no circumstance should one point only be carried high up above the shaft, as till comparatively lately used to be the universal practice in England; for one guiding principle is to avoid attracting the lightning—to "let the lightning come to you, but not to go to meet it." Several points are better than one, not only because the electric tension (by the influence of silent discharge) is thus more reduced, but because single points are occasionally fused or blunted by a flash, and this injury may remain for awhile unnoticed. Copper points should be so platinised, gilded, or nickel-plated as to resist oxidation. On account of this fusion or blunting of points the Lightning Rod Conference advised the use of a sky terminal, consisting of a stout copper rod having a short point (height equal to one-half of the diameter) to receive the flash without risk of melting the metal, and having at the same time, at 1ft. below the extreme top, a copper ring bearing three or four copper needles, each 6in. long, and tapering from ¼in. to as fine a point as possible, thus separating the double functions of a terminal point; whilst Dr. Lodge (in his lectures before the Society of Arts) suggested the use of cones of copper not too sharp, and gilded or otherwise protected against corrosion.

With regard to the choice for the form or section of the main conductor, of the various styles in use—rope, rod, ribbon, tube, plait, and tape—that most approved of by the Lightning Rod Conference is the copper tape. It is neat, easily fixed, flexible, and free from joints; whilst this section is considered to offer less resistance to the passage of electricity than any other. It should be about ⅝in. by ⅛in. thick, and weigh 6oz. per foot run. The junction with the upper band or coronal can be easily made by clamping and riveting the two surfaces together and embedding the whole mass in solder.

Materials for Conductors.—Iron and copper are the only two metals which can be advantageously adopted for lightning conductors. The Lightning Rod Conference recommend copper, but do not put it much before iron. If the latter be used it should not weigh less than 2½lb. per foot run. Copper has the advantage on the score of durability; on the other hand, it is much dearer than iron, and is more easily melted. The principal objection to iron is its liability to oxidation, but this is in a great measure prevented by galvanising. As iron rod, on account of its rigidity, cannot be used in long lengths, many joints have to be made, which is objectionable, because these joints are liable to rust, and thus destroy the metallic continuity. Copper has been generally adopted in England for many years past as the proper metal for conductors attached to all important structures, including chimneys of note. In America and the Continent, however, iron is much more in vogue, and has stood the test of a very long experience.

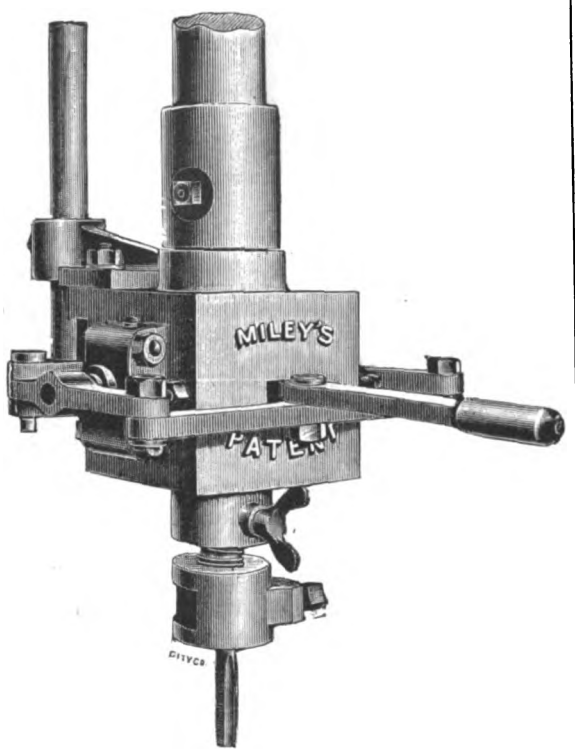
Mode of Attachment.—There must be no insulation, and the copper tape should be fastened to the chimney with holdfasts of the *same* material, to prevent voltaic action. The holdfasts should be driven in just tight enough to support the tape without distorting it, and so as to allow play for expansion and contraction. The conductor should be placed in such a position as to be least liable to corrosion from the gases, and also, if possible, where the extremes of temperature are at a minimum. Inasmuch as in this country the prevalent winds are from the south-west and north-east, the face or corner towards the north-west would seem to be the best position for it. The Lightning Rod Conference, however, recommended the side most exposed to the weather—*i.e.*, that which is usually more or less damp. An allowance in the length of the conductor has to be made for contraction and expansion—1in. in 40ft. is sufficient. Slight bends in the tape, if not too abrupt, answer this purpose very well. The bends necessary for passing over and through cornices and mouldings should be eased, inasmuch as lightning is apt to take a direct course, jumping over sharp turns in a conductor: in other words, the latter should be as straight as possible. The tape should not be bent at a greater angle than 30 deg. at any point of its length. As copper is a valuable metal, and offers a temptation to thieves, the tape should be carried in wrought-iron gas tubing for the 10ft. or 15ft. above the ground surface and for some few feet below it. It is considered best to connect the conductor electrically—*i.e.*, metallically—to all metal in the chimney, such as strapping and metal caps. Conductors are sometimes duplicated, which is a good

Digitized by Google

method, as it facilitates testing for electrical conductivity, &c.

Earth Terminal.—This portion of a conductor is of equal importance to the rest, and expense should not be spared to obtain a very good "earth." The best "earth" is water, and when a deep well or other large body of water is close at hand, the conductor should be carried down into it. The Lightning Rod Conference advised soldering the end of the conductor to a plate of metal (copper to copper and iron to iron, to avoid voltaic action) at least 3ft. square and $\frac{1}{16}$in. in thickness, buried as deeply as possible in a damp spot. A good earth may also be made by coiling the end of the tape or rod in a few tons of coke or ashes deposited in a soil which is always damp. The addition of a bag or two of salt is recommended, or rain water may be led there from roofs by stoneware pipes. Under all circumstances there should be a good, deep, damp "earth," and this can usually be obtained by boring, where other methods are not available. It is still better practice to have a duplicate "earth," bifurcating the conductor underground, and carrying each branch to a separate metal plate; the latter being surrounded, as before stated, with coke or ashes, which are good conductors of electricity. When there are gas or water mains in the immediate neighbourhood, the conductor should be connected to them metallically for their own protection; otherwise the lightning may jump across to them and injure them. Such mains, however, must not be relied upon as terminals, because they are often in dry weather badly earthed. When the mains pass under or have branches entering the building, it is best not to connect the conductor to them, but rather to place it as far as possible from their neighbourhood.

The painting of a copper conductor is optional, but an iron one is usually both galvanised and painted.



The providing and fixing of this important safeguard should be—and usually is, in the case of tall chimney shafts—left to firms who make this their speciality. It seems a pity, however, that a cheap, yet thoroughly efficient, conductor is not readily to be obtained in this country to meet the case of the small shafts which are so very numerous in various districts. If such were in the market, with clear instructions how to fix them correctly, many builders might feel disposed of their own accord to attach them to their chimneys, who, as it is, leave them unprotected. He who provides a good lightning rod not only protects his own structure but benefits the neighbourhood. The effect of the presence of many conductors in a town is—by the relieving action of silent discharge—to lessen the violence of the storms passing over it. Such has been the experience of Paris and of other cities.

Inasmuch as an ordinary chimney shaft is seldom built alone, but usually stands close to an engine-house or factory, it is not out of place to add a few words as to how these buildings may be protected. Terminal points are generally erected at the ends of all ridges, and they can sometimes be made a slight feature in the architectural design. The conductor should run along the ridges, and may be provided with short terminal points at intervals. It should be carried down all hips and corners of the structure to "earth," so as to cage the latter in, as far as possible, with metal. The different branches of the tape or rod should be taken to a good deep "earth," and by preference to earth at several points, care being taken—as before stated—to have soldered joints and to avoid galvanic action, &c. Rain water spouts, vanes, finials, &c., and all outside metal should be in perfect metallic connection with the lightning conductor, and, generally, with one another; but it should be kept well away from soft metal and small bore pipes and from internal gas pipes of every kind. Some judgment is required in this matter as in that of connecting to water and gas mains. A cheap method of protecting a building, and one which is recommended on high authority, is that of using ordinary stout galvanised telegraph wire for the conductor, carrying it up all corners, along all ridges, hips, and eaves, and up chimneys, taking it down to "earth" in several places, and at each place burying a load of coke or cinders. It stands to reason that, whatever style of conductor be adopted, the general course of the path offered to the possible flash of lightning, from sky end to earth, should be as direct and as vertical as possible. For instance, right angled changes of direction in the conductor from the vertical to the horizontal and back to the vertical, in order to avoid a roof or to lead it from one face of the building to another—as is occasionally to be seen in the case of lightning rods attached to modern structures—should be avoided. The course chosen should be one more or less diagonally downwards—*i.e.*, one making a considerable angle with the horizontal.

Finally, when the lightning conductor is in place it has to be electrically tested; an operation which is best entrusted to an expert. This testing has to be repeated from time to time in order to ensure the conductor being in working order; and to make provision for this a wire is sometimes, in the first instance, metallically connected to the upper end of the conductor and brought down to the base, being attached to the structure in the same manner and with the same care as the conductor itself. If this practice were universally followed, the periodical testing of conductors would not be so much neglected as it undoubtedly is.

MILEY'S PATENT TAPPING TOOL.

The tapping tool shown below can be used on any ordinary drilling machine, without the machine having to be fitted with a reversing motion. Special taps are dispensed with, as the appliance is made to work with ordinary machine taps with square ends of various sizes. Any breaking of taps is avoided, as the tapper is so constructed as to convey to the handle a percentage of the pressure on the tap, and the moment undue resistance is offered, or the tap comes to the bottom of a hole, it is detected at the handle, and the working instantly stopped or reversed. The tool consists of a square box, jointed in the centre, and enclosing five mitre wheels, all of which have turned bosses at their back. These revolve in bearings arranged in the sides of the box. On the driving wheel is a shank which fits into the spindle nose.

The driving wheel supports the box on its back, and the box is prevented from revolving by a rod at the back. The spindle wheel has a hollow boss at both sides, and the part at the back takes a bearing in a recess in the driving wheel. The spindle is fitted inside this boss, so that it can rise and fall with the tap, and the end of the tap is provided with an adjustable driver, to suit the square of the various sized taps. The remaining three bevel wheels are arranged at right angles to the other wheels, two of them being horizontally opposite to each other, to the right and left of the vertical spindle, and the other at the back. The latter wheel always retains its position, and is always in gear with the driving wheel; the other two wheels are arranged so that their bosses can slide in the sides of the box, and each is brought into gear in its turn and held there by the compound levers shown in the illustration. The tool is made by Messrs. Dean, Smith, & Grace, Worth Valley Tool Works, Keighley.

THE IRONMONGERS' EXHIBITION.

This Exhibition, which was started by Mr. H. Etherington as a purely ironmongery Exhibition, has now developed itself into an "International Exhibition of Machinery, Manufactures, Appliances, and Inventions Incidental to Engineers, Electricians, Builders, and Ironmongers." The Exhibition was opened on the 17th inst., at the Agricultural Hall, Islington, and will be closed tomorrow. The exhibits are less imposing than the length of the title of the Exhibition would lead one to believe, but although a good many of them deserve the respect which is due to old age, inasmuch as they have figured at exhibitions for many years past, some novelties are presented. It is almost needless to say that on the opening day affairs were in a somewhat backward condition, but they have now got into order.

Messrs. Alldays & Onions, of Birmingham, have numerous types of smiths' forges with hand blasts, and a Roots blower driven by a small steam engine. They have also a pneumatic hammer.

Some handy little tools are exhibited by Mr. J. Parkinson, Chester Street, Bradford. Among them is a small drill for foot driving, and a combination breast and table drill for holes up to $\frac{5}{16}$in., and a very neat lathe. A vice is also shown for heavy work with a very ready adjustment.

A good show of gas engines is made. Several "Otto" gas engines are shown by Messrs. Crossley Brothers, and one of 14 h.p. is in motion running a Thomson-Houston dynamo, supplying current to thirty Thomson-Houston arc lamps of 1,200 c.p. Messrs. Dick, Kerr, & Co., 96, Queen Victoria Street, have seven of their "Griffin" gas engines, one running a "Tyne" dynamo of Messrs. E. Scott & Co., Newcastle-on-Tyne, for the supply of twelve arc lamps. This firm also shows a "Fife" arc lamp of simple construction on the lines of the "Pilsen-Joel" lamp. The "Stockport," the "Campbell," and Atkinson's "Cycle" gas engines are well represented. We also noticed a new gas engine made by Fawcett, Preston, & Co., Limited, Liverpool, which is called the "Fawcett." The advantages claimed for this engine are its extreme symplicity of construction, the ease of starting, and an impulse at each revolution.

Wood working machinery is represented by Messrs. Lewis & Lewis, of Cambridge Heath Road, London; Messrs. L. Amette & Co., 291, City Road, E.C.; and Messrs. E. Jacobs & Co., 105, Queen Victoria Street, E.C. The last firm has a large exhibit, which includes band saws, tenoning machines, hand and power feed surfacing and thicknessing machine, single deal frames surface planer and jointer, four-side inch moulder, and a self-contained circular-shaped recesser and surface moulder. A most ingenious arrangement is that shown by the Folding Truck and Carriage Company, Bellevue Street, Swansea, by means of which a hand-cart 3ft. 6in. in width folds up to 1ft. 6in.

Messrs. Winnal, Callow, & Winnal, Bromley Street, Stepney, have various electrical appliances, including an electric ship's bell. They also exhibit a small "Phœnix" dynamo, not in motion, and a model of Newall's rotary engine.

The Incandescent Gas Light Company, Limited, 3, Victoria Mansions, S.W., have introduced into the Welsbach lamp an improvement in the method of attaching the mantle to the burner. Several regenerative lamps are on view, including the "Champion," made by the Champion Gas Light Company, 37, Southwark Bridge, S.E.; the "Meteor," of Messrs. Henry Greene & Sons, 153, Cannon Street, E.C.; and the "Thomas," of the Thomas Lighting Company, Limited, 15, Carthusian Street, E.C. The last mentioned is specially prominent by the brilliance of its light. Messrs. J. Stott & Co., 174, Fleet Street, have their well-known gas governor on view; they are introducing a new type of sunlight for theatres and workshops. Mr. Joseph Shaw, Albert Works, Lockwood, Huddersfield, is represented by his gas governor, which is shown in different sizes. Mr. H. L. Müller, 22, Mary Ann Street, Birmingham, has some of his "Alpha" portable gas making machines, but these are not at work.

Mr. Dan Rylands, of 62, King William Street, London, shows his patent glass-lined metal piping, which he has just put on the market. This patent piping consists of a distinct internal solid glass tube, which is covered and protected externally by ordinary iron tubing; a suitable cement is inserted between the glass and the iron, making the whole homogeneous, and at the same time rendering this new piping unbreakable by ordinary use. Tee-pieces, bends, elbows, and crosses can be similarly manufactured with the internal solid glass lining. The advantages claimed for glass-lined tubes are many, and they would appear to have a future before them for chemical and electrical purposes.

THE PROGRESS OF BRITISH WATCH AND CLOCK MAKING.*

The one fact which the late Paris Exhibition has made patent is that the English watch and clock making trade has awakened from a long lethargy and has entered on a veritable Renaissance. At Paris, there were altogether 500 clock and watch making exhibits, coming from Austria, the Argentine Republic, Belgium, England, France with five centres (Besançon, Haute Savoie, Beaucourt District, St. Nicholas d'Alièremont, and Paris), Italy, Japan, Roumania, Switzerland (with its 147 exhibitors), and the United States of America. Of these 150 were watch and 37 clock manufacturers, and these are the sections that will be the subject of my paper.

Taking the class of watch manufacturers, the somewhat large number of 150 exhibitors may at once be separated into two

* Paper read by Mr. Julien Tripplin before the Society of Arts on the 5th inst.

Digitized by Google

groups, viz.:—*A.*—Manufacturers by the new mechanical processes, that is to say, those who by means of steam or hydraulic power, new appliances, improved organisations, and larger output, make the whole or part of the watch on the interchangeable system. *B.*—Those makers who follow the old mode of watchmaking, still almost exclusively in use in Clerkenwell, partly at Coventry, and also at Besançon and parts of Switzerland, wherein the rough movement is produced in places which are far distant from those localities in which the finishing operations of jewelling, dial-making, 'scaping, chasing, finishing, timing, and adjusting are done under a system of sub-letting to small makers who work at their own homes.

Of the former there were 25, and of the latter 125 exhibitors. Dividing these again into nationalities we found that in Group *A* (25) England had 1, France 6, Switzerland 16, America 2; while in Group *B* (125) England again had 1, France 49, and Switzerland 75. This classification is, of course, not sharply defined as in some cases it became difficult to discriminate, but it facilitates the task of examining and comparing.

The importance of the question of watchmaking by mechanical processes, suggesting as it does a large, complicated, and complete manufacture, deserved some analysis. A small amount of investigation made it clear that under this heading were grouped a number of manufacturers who differed widely in the extent to which they carried out the principle; indeed, five fairly-well defined divisions were seen to exist. These may be stated as follows:—*A.*—The watchmakers using automatic appliances more or less in the making of plates and barrels, and of various parts of the watch, but who obtain wheels and pinions from outside their own organisations. *B.*—Those firms making the movement complete, including wheels and pinions, but not the parts of the escapement. *C.*—Those who couple the finishing process with the operations of Group *B*, but who yet obtain the parts of the escapement outside. *D.*—Firms who add casemaking (sometimes only in metal and silver, sometimes both in silver and gold) to the operations of Group *C*; still, however, obtaining the parts of the escapement from elsewhere. *E.*—Those firms whose organisation embraces the making and finishing of the whole of the parts of the watch and the case, except the specialised parts of the mainspring, balance-spring, hands, and perhaps jewel holes. Accepting these divisions as in the main indicative of various degrees of watchmaking by machinery, although it is true they interlace in great complexity, and applying this analysis to last year's Exhibition, it was noticed that Switzerland, so strong in collectivity, was comparatively weak in work of type *E*. Looking at the testimony of the exhibits themselves, we found none that realised the conditions of Group *E*, except the English firm of Rotherham & Sons (and perhaps that of Messrs. Japy Frères, and the well-known Waterbury Company of America; but these two firms only deal with metal-cased watches of less than ten shillings in cost, and can scarcely be considered when speaking of watches of precision), and this firm thus at once attracted attention, even among so large a number of exhibitors taking part in the competition. It is difficult to assign a reason why the Swiss have not yet carried their revision of operations far enough to cover the ground that the American and English companies consider the ultimate necessary extension of the modern mode of manufacture. Probably the causes are manifold; it may be that a large command of skilled labour and an extensive subdivision in their older method have created certain vested interests in the community and make it more difficult to change; or it may be the large capital required and the absence of joint stock enterprise in Switzerland. Again, the cheapness of their productions, made under their old methods, would naturally at first render them freer from competition, and so necessity, which on close investigation is always seen to be the compelling agent, was not early felt by them. Be this as it may, there can be little doubt to-day of the enormous gain of carrying the combinations to the extent of Group *E*; it is, in fact, the only rational course which meets the requirements of this present time.

Before entering into a more detailed consideration of this Group *E*, which forms the main body of my remarks, allow me to say a few words on the British section as it was arranged in Paris last year. This section had a compact and collective appearance, and as such arrested attention. The exhibitors were chronometer-makers, turret-clock makers, and watch manufacturers by both methods; a school of horology, tools and materials, and literature were also represented. It differed widely from that of previous exhibitions in many ways. Formerly the few exhibitors were scattered about, and their stands arranged with small counters for purposes of sale, justifying in some measure the Continental sneer "that England is a nation of shopkeepers." In the present instance the very reverse was the order of the day, the firms exhibiting were of weight and substance (chiefly *bonâ fide* manufacturers), and were for the most part induced to do so from patriotic motives, endeavouring to counteract by ocular demonstration the feeling which had begun to take root in the public mind, that English watch and clock making was a thing of the past. The representative character of the exhibitors and the substantial merits of their exhibits greatly impressed the jury, and obtained for our section the unprecedented number of awards it received; in point of merit, the watch and clock making section stood before all others in the Exhibition. In chronometry Mr. V. Kullberg carried the palm from all competitors. Messrs. Dent, of the Strand, and Gillett & Johnston, worthily sustained our reputation for public clocks, this last firm emphatically so. Messrs. Grimshaw & Baxter's exhibit of watch and clock tools and materials was large, and representative of the excellence of our products in this particular; while Messrs. Usher & Cole, Parkinson & Frodsham, and Webster, of Queen Victoria-street, showed that the traditional skill of Clerkenwell was still the best of its kind. For the first time, too, an English school of horology presented itself to the consideration of a jury, and we must note, in this new departure, a happy augury for our future. As tending in the same direction should be classed the translations into English of Saunier's textbooks for schools and workshops by Mr. Edward Rigg, jointly with myself.

But the exhibits I have selected to illustrate my conclusions to-night are those of the British United Clock Company of Birmingham, as regards the manufacture of the cheap drum clocks (with which American and French firms have flooded the markets because of their singularly low price); and the old and important house of Rotherham, of Coventry, as regards the manufacture of standard types of English lever watches. I may say that the latter's exhibit was intended to show the reorganisation that English watch manufacture has undergone during the present decade, and the result is, perhaps, best shown by quoting two criticisms by foreign experts. One was delivered by an eminent Swiss writer, who said of the English trade, as represented at the Paris Exhibition of 1878:—"It is complacently asleep in the conviction of having raised limits which its rivals or successors can never surpass" The other criticism is taken from the *Revue Chronométrique* of November, 1889, and is from the pen of Mons. E. Antoine, one of the Besançon jurors, himself a watch manufacturer of the first rank. He says of this firm, in showing the application of machinery to watchmaking:—"It equals, if it does not surpass, its predecessors in every country." We have here a complete reversal of previously existing impressions, and this should be highly gratifying to every Englishman. The exhibit was in itself very simple; it consisted of a connected series of pieces of the movement, showing, step by step, the condition of each part as it passed, process by process, from the raw material to the finished work. Every part of the watch was illustrated in this way, and so arranged as to convey a clear indication of the methods, and to show the nature of the machinery employed throughout the whole of the manufacture. In like manner the making of enamel dials, of gold and silver cases, and of pendants and bows, were exemplified; but simple as it was, it was readily seen by the jury that they had under their consideration as complete an organisation as could be found in any country. The various branches of watch manufacture were found to be all brought under one control, and each of those branches had been revised in its methods by the introduction of automatic machinery of the latest type. By a series of photographs it was also seen that they were manufacturers of their own machinery and appliances, and it was elicited by the jury that in their tool-making a regular system of measurements and gauges secured the advantage of interchangeability in the lathes, engines, and general machinery of the place.

I will try to make clear the essential difference between the old and the new methods of manufacture. It is generally known that in the very early days of watchmaking the whole of the mechanism was the handiwork of some master craftsman, who designed and fashioned all its parts from crude metals, and even worked up the metals themselves, by his own peculiar treatment, into a condition of special fitness for his wants. This craftsman, with mechanical aptitude of the first order, was of good education and wide reputation, and such workmen were often retained by emperors and princes for the making of costly gifts. The whole of the operations were thus concentrated under one roof and control, with a high level of education in the worker. After this time came the usual evolution, differentiation began, and slowly we find the making of the parts more and more subdivided, and specialists in the various branches combining their work to form the whole machine, resulting in a very great advancement in quality. Further divisions and sub-divisions follow, also further raising of the standard of excellence, until the errors of time-keeping fell from five minutes a day to less than one minute a week. But all this was attended by a greater and greater separation between the workers. Beginning by occupying different houses in a given district, and then different districts in a town, they eventually became distributed over the whole face of the country, until the loss of time in fetching and carrying became from 10 per cent. to 20 per cent. of the cost. Even this, however, was not the most serious evil. Absence of control gave rise to the much greater disadvantage of a loss of unity of proportion and of evenness of quality; excellence in one part joined mediocrity in another, this being discoverable even in the most costly watches; and, finally, the impossibility of bringing such a disconnected course of working under fixed standards of reference or under a uniform system of exact measurement, brought about such a condition of things that at last a point was reached when the advantages of specialisation were balanced by the want of dovetailing in this disjointed and cumbrous procedure. Such was the condition of things up to forty years ago, when these drawbacks gave rise to the desire in many minds to get back the advantages of unity of control without losing the advantages springing from sub-division and specialisation; and this is exactly what has been secured by the new system of manufacture in large factories. The system is fundamentally sound and logical, because it secures the union of these advantages. The twenty odd branches of the trade are once more aggregated under one roof and control; an extreme sub-division is set up, and the whole fabric linked together and governed by a rigid system of measurement for the size and proportion of every part.

The increased application of machinery, associated with this revised method of manufacture, excellent as its results are, is, one may say, almost secondary in importance to the reorganisation which this re-grouping of the trades admits of; but when the automatic processes are added to this reorganisation, we have the powerful weapon which gave the Americans, who early adopted it, a leverage in economic production which threw the old manufacturing centres of Europe for a moment into confusion and panic. The American companies were thus able to develop themselves on a vast scale, and to obtain almost complete control of their own markets before the other countries had time to reform. It is now difficult to dislodge them, although it has long been evident that, with anything approaching equal manufacturing facilities, the old centres would once more invade American markets were it not for the existing heavy prohibitive duties.

It has been said that an extreme subdivision is made possible by the factory system; this involves as its corollary great quantities in manufacture. It has been further said that this specialising of the functions leads to increased excellence, but it has this further advantage that, for industrial purposes, it enables the creation of skilled labour in the least possible time. Take, for instance, the formation of a balance-staff-cone pivot; a lad can be taught in two or three months to pivot a staff in a style that would not be possible without several years' practice in the old order of things, and, from doing but this one thing he quickly obtains a dexterity that surprises, until it is remembered that he has made more pivots in six months than an ordinary watchmaker, in the old way, would make in a lifetime.

It should be pointed out that one of the special difficulties in establishing a watch factory is that—until quite recently—it was not possible to purchase the machines indispensable to commence the manufacture. It was necessary to begin by starting an engineer's shop, in which to build up the tools and machinery; and to design these, to make the patterns, and to make a long series of machines, required some years of preparation.

In the "plate room" of Messrs. Rotherham's all the brass parts of the movement are turned and milled into the required form and size, as well as the drilling and tapping of the holes, the steady pinning of the pieces, the planting of the position of each wheel, and the boring out of the recesses to receive the jewel holes. The parts are received here from the press-room, where they have been stamped out to a given shape, and are here finished ready for gilding. Girls are largely employed in these operations, as the machines, when set up to measurement by the foremen, are rendered wholly independent of the skill and judgment of the worker. Quickness, care, and cleanliness are the only requirements. Gauges, verniers, and micrometers are *de rigueur*, to check the wear and tear of cutter edges and points. Fines are imposed if anyone is found working without a periodic testing of their work by the standard. An independent office examination of the pieces when completed gives a further check to these precautions. This is one of the strong points of a factory organisation. It is desirable to note here that an essential difference between the old and new methods shows itself at this point. There is no roughing the part out somewhat nearly to its right proportion, and then passing it on to another workman to remake it smaller, to refit it, or to shorten it to the right height and length, thus practically travelling over the same work twice. This was the custom formerly; but now a book of drawings of each piece is furnished to the foreman who has to set the machines, and therein a diagram and measure are given for every cut made upon the piece, so that it is reduced at once to the proper dimensions with quickness, directness, and with the certainty that it will coincide with the part it is to be attached to. There is obviously a minimum waste of time in this way.

In another room the workers are engaged in making the steel work of the watch—that is, the cutting of pinions, ratchets, springs, regulators, studs, and numerous steel pieces of strange shapes which constitute the keyless mechanism. The directness of procedure is again apparent in the fact that, contrary to the older plan, the pinions are at once turned to the right height of head, the arbors to the right length between shoulders, and the pivots to the right size according to the diagram of measurements furnished to the foreman of the department. No hesitation or mental debating as to proper size is called for; that has all been decided in getting out the original drawing and model from which the measurements are obtained, and action, and nothing but action, is now the order of the day. The general rule of this department is that all finishing operations are done by automatic machines, which only require the operator to feed in the "blanks." The approach of the cutter to its work, the travel, or feed, and the withdrawal of the cutter and the stoppage of the machine, and the completion of the operations, are functioned automatically, leaving the worker free to attend to several machines, or prepare the blanks, or cleanse them. The reason why these machines are not made self-feeding is twofold: firstly, the minuteness of the parts, and secondly, the need of clearing the centres and surfaces of chucks and cutters after each operation, when dealing with such minute pieces and with such exact measurement.

In the next shop the workers are all skilled hands engaged in putting the parts of the watch together, and in timing and adjusting, and in casing the movements. Messrs. Rotherham receive the time current daily from Greenwich for this purpose, and the low, middle, and high temperatures are obtained by refrigerators and ovens placed under ground, and kept within a variation of one or two degrees Fahrenheit all the year round.

In illustration of the kind of economy obtained by the latest labour-saving appliance, let us take the case of a wheel—that most important element in a watch. A watch wheel has four, five, or six arms or spaces, formed to give lightness to it, and these are stamped out in a press, and in cheap watches it is left so, but the act of stamping out these spaces leaves a very rough, torn surface where the metal parts, and hitherto it has been the habit to laboriously file and scrape the surfaces of every arm, web, and boss to give squareness and finish to the object when completed. This required some skill, and was a costly operation of a minor kind; but I will refer to a new kind of sub-press or cutting instrument (Figs. 1 and 3) which is devised to cut just a thin shaving off all the twenty sides and surfaces of a five-armed wheel at one stroke; the operation, including the fixing of the wheel, is accomplished in less than thirty seconds, and, what is more, leaves the wheel in perfect poise. The whole of the parts are fitted by a slow process of polishing when hardened, and this fact, coupled with the fact that it must be related to the previous punch, which forms the spaces by very exact measurement, makes this a very costly tool. Messrs. Rotherham's is the only place in England where this is practised.

The formation of the pivot of a watch is an operation of the first importance. In Fig. 2 is an apparently simple machine in use for this purpose at the factory at Coventry. The principle on which it is built is the recognised one for securing perfect roundness—viz., the work revolving one way and the polishing disc rotating at high speed in an opposite direction. The driving band or gut, it will be observed, is arranged to take off all side pressure from the spindle, and this leaves the "feel" or touch of the worker's hands unimpaired. A device consisting of an inclined plane and roller is added at the base of the machine, which, by adjustment, will give any desired taper to the pivots. The pivoting is all done to ruby holes of standard sizes.

In illustration of the control in detail made possible in the new system, I may mention a machine (Fig. 4), the sole function of which is to repair the polishers used on another line of machines, in order to insure uniformity of form when the polishers require renovation from slight distress in wear. This machine is used to preserve a uniform shape on the cone of balance pivots, and is simply a type of a line of tools, existing in a well-organised factory, to preserve unchanged the curves and angles of polishers and cutters under the strain of constant use and repairs. Running in a head-stock is a revolving abrader, which may be either a file or emery disc. To this is presented the polisher, moulded in a holder having a circular motion. The radius of the curve given to the edge of the polisher is regulated by the distance it is fixed from the centre of motion of the holding frame, and this distance is an adjustable one.

Perhaps there is no part more difficult to deal with by machinery than the pallets of a lever watch, and especially is

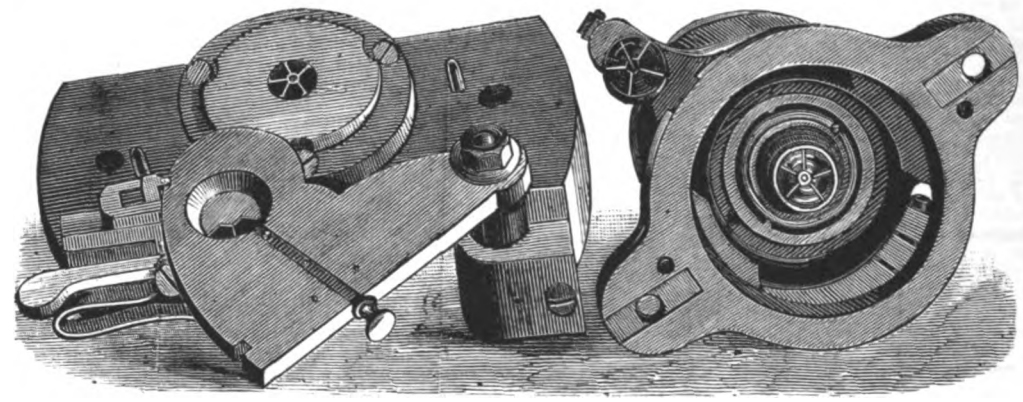

Fig. 3.—Portions of the Sub-Press Wheel Shaving Machine.

this so in the form which it assumes in an English lever, where, for the purpose of being secured against any sort of accident in use or repair, the slips of ruby are encased in steel. In most cases the difficulty has been evaded by adopting some other form more convenient for the application of machinery; but Messrs. Rotherham were very desirous of preserving this distinctive feature of the English watch, and, after a rather considerable outlay in experimenting, they were able to produce a line of tools which gave excellent results. Fig. 5 shows a view of the semi-automatic cutting engine for forming this English form of pallet. Here the whole of the nine angles that have to be cut are expressed on a dividing plate, and the blank pallet (mounted on its pallet holes and the two lever pinholes) is cut to these angles, all in absolute relation to one another, in the same manner that the teeth of wheels are cut; the three cutter spindles that revolve are shifted by hand as each cutter is brought into action, but the eighteen stops required and geared together are all moved automatically by the up movement of the cutter handle. The principle in the design of this tool is that the angles cut on the pallets shall not depend upon any angle given to the cutters, but be cut by square-faced cutters easy to produce. Similar devices permit of the polishing of these faces after the insertion of the slips of ruby.

The operations of working the precious metals are necessarily directed to guard against waste, and to this end do away with filing or scraping, or the making of shavings by turning, or any operations which, by producing dust or minute fragments, result in loss; and further, to do away with soldering the parts together, as this involves filing or dressing in some way the points of junction. The modern method, therefore, is to treat metals as plastic material, and force them by pressure into the required forms and thicknesses. The metal is rolled down into a ribbon of given thickness, and then a disc of a calculated diameter is stamped out, and then fashioned into a cover as follows:—A disc (Fig. 6) is placed in a cupped die under a strong screw-press, and a stamp of corresponding shape with one blow turns up the disc into the form shown in Fig. 7. A second stamping turns over the edge a little for the snap, as in Fig. 8. A third continues the formation of the snap, and completes it as in Fig. 9. The die used in the foregoing operations has a groove to correspond with the bead required on the bottom, but as yet the bead is not well defined, and therefore a stamp is now used, the contour of which, instead of following closely the outline of the die, bears hard on the points where the beads should be. A blow from this gives the requisite fulness and sharpness to the bead, as shown in Fig. 10. Well and uniformly shaped bottoms are thus produced without soldering. The snaps and outer surface of the bottom are skimmed in the lathe. However necessary turning might be for the snaps, it seems like painting the lily to apply the lathe tool to the already smooth and finished surface of the remainder, but the silver would not yield the particular high polish desired unless the skin of the metal were first removed.

The making of machinery for gold and silver cases is an industry which has kept pace with that for dealing with the watch movement. In Fig. 13 is shown a view of a tool designed by Messrs. Rotherham to cut the spaces and recesses into which the knuckles or joints of the case are to be soldered. These spaces are cut by a revolving cutter, at a fixed distance from each other, by means of a dividing plate, and a novel invention is introduced into the machine for securing the truth and accuracy of the depths of the hollows, in spite of the twisting of the case under the heat of soldering. This spacing on a dividing engine, and providing for the distortions of metal in soldering, strikes one as refinement in manufacture.

The British United Clock Company is a company formed for the production of cheap lever drum timepieces and alarms, a work hitherto monopolised by foreigners, and in the short space of five years they have successfully checked the importation of these goods. The production of the company has reached 500 clocks per diem. This may appear a large number, but is comparatively trifling compared to the demand. The best appliances have been laid down, and the factory, although it covers 1,250 yards, and is fitted with engines of 70 horse-power, as yet only covers one-third of the ground acquired for future extension. An excellent machine room is established for making dies and machines, and for repairs. This and an extensive press-room are fundamental requirements in such a manufacture.

A simple recital of a few of the operations in making these clocks may interest those unacquainted with the care and precautions made possible in large works, even where the goods are sold at the singularly low price at which these clocks can be obtained. The wheels have their teeth cut in an engine in place of being stamped out, and the pinions are no longer made from "drawn" pinion-wire, but are also cut in an engine, three cutters in succession traversing each leaf, and they are then subject to a certain degree of polishing. The mainsprings are tested individually after hardening.

There is a very neat invention in connection with the winding of the Speedwell alarm. The great wheels of the going and alarm trains are mounted on the winding arbor, one on each side of the mainspring, which serves to actuate both. The wheels are loose, and driven by ratchets and clicks to allow of the arbor being reversed to wind the spring, the outer end of which is attached to the great wheel of the going train. When the alarm is let off, the force of the spring will cause the winding arbor to turn and carry with it the great wheel of the alarm train. But the problem is to lock the spring again when the alarm has run its course. On the winding arbor is a pinion with coarse teeth taking into a segment having a strong butt, which forms the alarm stop. In winding the piece, the first turn of the winding arbor winds the alarm stop, if it is down, and a missing tooth in the segment allows the winding of the going train to proceed in the usual way. This is made clear in Figs. 11 and 12, where the wheels and segment are shown as they appear before and after winding. There is, it will be observed, a light spring, which presses against a pin in the segment when it is wound, thus keeping the butt away from the pinion, and ensuring the engagement of the pinion and segment teeth when the alarm is let off. The arrows in Fig. 11 indicate the course of the wheels in winding, and the arrow in Fig. 12 the direction in which the segment will move when the alarm is in action.

In evidence of the thorough-going way in which the company uses every modern aid in furtherance of its work, I may mention that the cases of these clocks and the ornamental dials are prepared for gilding with that peculiar soft grain known as "satin-matt," by the use of a steam sand blast, the process being as follows:—The object is placed in an air-tight box and over the orifice of a pipe containing the sand; the box is then exhausted of air and a jet of sand impinges on the metal, and in a few seconds it has the desired matt. The energetic way in which the management attacks the difficulties that arise is shown in this fact that, finding the brass supplied in Birmingham is not so good for the purpose as that obtainable in America and Germany, because the sulphur from the coal used in annealing injuriously affects the surface of the metal, and shows itself as an uneven surface after being "dipped," it is now preparing plant to make brass with the object of overcoming this defect. Such great energy and enterprise, as I have alluded to, leads one to understand how, in the short space of less than five years, this company found itself strong enough to venture on competition with the whole world in an international exhibition, and in the opinion of many competent judges did so more successfully than even their Paris award indicated. There is here a lesson of what may be accom-

plished by a union of intelligence and energy on the one hand and capital and commercial capacity on the other; for it must always be remembered that it is not enough to make the goods, but that to distribute them with sufficient rapidity and volume is an essential of success where great producing power is developed.

I hope this hasty glance at these few details may have served to convey an idea of the manner in which watches and clocks are produced by the new method, and that you will perceive that it is not of the nature of a new discovery, but rather a development from our past, and that, as is common in such a case, is attended by an increasing complexity, which requires greater grasp and width of knowledge, and more organising power on the part of those who conduct it. The superintendents, foremen, and sub-foremen of the various departments have not only to know all that appertains to their own proper business, but to deal with the details and functions of the complex machinery set in motion to produce these watch parts, and they have, further, to conduct operations on a much larger scale than has been the custom hitherto. All these requirements demand new facilities for acquiring this special knowledge, and imperatively call for the specialisation of theoretical training in schools equipped with a proper range of teaching appliances. Our continental rivals have long recognised this fact, even before the advent of this complicated machine system, and the magnificent display of their ten horological schools at Paris last year testifies to the importance attached to this educational machinery abroad. It is true that for the first time in our history we had a Clerkenwell school exhibiting side by side with these foreign schools, but the comparison naturally showed our weakness, and the great advantage it is now to the foreigner that he established these training centres a generation before us. The necessity for these schools amongst us has become so great of late, owing to the gradual decrease of the apprenticeship system, that we are not without some movement in the desired direction, for a second school has been established in London and one at Edinburgh; while Coventry has, within the last two years, established one in connection with the technical institute in that city. But in view of its supreme importance this matter moves too slowly with us, and it is to be hoped that the energy and thoroughness which distinguishes the English character will display itself in anxiously promoting and fostering schools of horology.

These remarks bring me to the conclusions at which I have arrived after a careful study of the horological display at Paris. I find that in comparison with our competitors our position to-day stands as follows:—1, In chronometry we are supreme; 2, In two or three branches of the clock trade we have a decided lead; 3, In the manufacture of the cheaper kinds of clocks we show a successful and hopeful new departure; 4, I find that the cost of our best grades of adjusted watches is now as moderate as is the corresponding grade of foreign work, while the gradual elevation shown by the timing records at the Kew Observatory trials testifies that their excellence is being steadily advanced year by year; 5, The records of our deck watches under the severe trials of the Greenwich Observatory show performances unequalled in the world; 6, As I have shown, in the important matter of watchmaking by machinery we have, during the past ten years, vigorously pushed ourselves to the front rank in quality and organisation, for besides the large factory of Messrs. Rotherham, we have in London those of Messrs. Guye & Company, and Nicole, Nielsen, & Company, and two in Birmingham, that of Messrs. Erhardt & Company and the English Watch Company; besides these a new organisation is now arising in Coventry, while only last month Lord Derby attended the opening ceremony of the new Lancashire Watch Company in the village of Prescot, a very old seat of watchmaking.

Now, taking the contrary impressions, I am struck with the, to me, unmistakable evidence that the following points of advantage which the foreigner appears to have over us is closely, if not solely, related to his having so long possessed those specialised educational advantages we are in the habit of speaking of as technical instruction. In the first place, then, he is decidedly superior to us in the variety and flexibility of his manufactures, in the wealth of his style, and in the beauty of his decorations; 2nd, in many branches of clockmaking, notably in mantelpiece clocks, where the decorative art comes into play, he holds a decided monopoly; 3rd, in the application of electricity to horology he is considerably more advanced than we can claim to be; 4th, in all that relates to the synchronising of timekeepers, whether by electricity or pneumatically (although perhaps this is debateable ground), I fear we must grant the foreigner a foremost place. In considering these four points, I venture to reiterate the thought that they are all more or less related to the widened mental condition that comes from special training in the science and technics of the art. I have estimated that the ten schools exhibiting in Paris have during their existence trained more than 7,000 students, who have passed out and taken positions in the trade as manufacturers, foremen, &c., and thus become centres for extending the knowledge they have acquired.

FOREIGN INDUSTRIES.

(From our own Correspondents.)

(FOR LATEST TELEGRAPHIC DESPATCHES SEE PAGE 297.)

PARIS, 25TH MARCH, 1890.

COAL.—The effect of the dearth of coal, due partly to strikes among the miners and partly to greater activity in the iron trade, is distinctly visible in the Customs returns recording the imports of coal in the first two months of the current year. Throughout 1889 there was a constant falling off in the deliveries of foreign coal. Now the import trade is increasing, and the increase has been such that the quantities received for consumption in the country compare favourably with those of the corresponding period of last year—1,312,058 tons, against 1,166,124 tons. The particulars of which this total is made up show an increase from all sources. Thus we have from England, 666,357 (550,982) tons; from Belgium, 552,140 (530,071) tons; from Germany, 91,131 (84,995) tons; and from other countries, 2,430 (76) tons. The coke imports in the period in question amounted to 181,367 (165,424) tons. The quantities in parentheses are those for 1889. There is a falling off in the coke trade with Germany, where the home demand has for some time past exceeded the supply. Very little English coke is shipped to France.

IRON.—The improvement which was brought about in the iron markets of this country by the colliers' strike in England is maintained, and the rates have become firm on the announcement of a considerable permanent increase in the cost of English coal. Our merchants here refuse to accept less than 160s. a ton for bars and 164s. for joists; but it must be confessed that they are doing but little business. The requirements of consumers are now very small, and there is no prospect of a larger demand. In the provinces the markets are on the whole fairly active; but buyers are chary of entering into large contracts. In fact, consumers do not believe in the maintenance of the present rates for any great length of time. There is more life in the district of the Haute-Marne than anywhere else. In the Meurthe-et-Moselle the pig iron trade is somewhat slack. The declared value of the exports of iron and steel of all sorts in the first two months of the current year amounted to £244,280, against £59,680 in the corresponding period of 1889.

STEEL HORSE COLLARS.—The latest application of steel to a new use is to be learned from the circulars of the Société du Harnachement Métallique, a company formed here for the manufacture and sale of steel horse collars. The collar consists of two halves of a U jointed at the bottom and joined at the top by a clasp of arched form. The weight is from 8lb. to 12lb.

THE TRIAL OF ELECTRIC METERS.—The electrical authorities of Paris some time ago offered several prizes for the best instruments for recording the consumption of electrical energy, with a view more especially of choosing a suitable meter to use in the systems of electrical distribution. A large number of makers sent in meters, viz.:—Desroziers, Aron, Ferranti, Richard, Bauer, Cauderay, Jacquenier, Leslie, Batault, Weber, Brillié, Clerc, and Blondlot. Although the judges considered that none of these were sufficiently excellent to deserve the premium offered, the following grants were made:—M. Cauderay, 2,000fr.; M. Aron, 2,000fr.; M. Brillié, 1,000fr.; M. Blondlot, 1,000fr.; M. Jacquenier, 1,000fr. On account of the premium not being awarded, and also because several meters arrived too late, the judges have decided to hold another trial in August next.

ELECTRIC LIGHT AT THE VAUCLUSE HOSPITAL AND REFUGE.—The hospital and refuge at Vaucluse, near Paris, which is intended for the reception of foreigners, has had an electric light installation since November last. This installation is supplied with steam from three Belleville boilers, whose heating surface is 26 square metres, and which give 600 kilogs. of steam per hour at a pressure of 12 kilogs. per square centimetre. The steam is collected in a common chamber, from whence it passes at a pressure of 6 kilogs. per square centimetre. There are three vertical engines made by Messrs. Breguet, of 30 h.p. each and 350 revolutions per minute. Each engine drives a Desroziers compound-wound dynamo of 140 amperes, 122 volts, and 850 revolutions per minute. The service comprises 322 incandescent lamps of 10 c.p., and 243 incandescent lamps of 16 c.p. The hygienic conditions of the hospital have been immensely improved since the adoption of the electric light.

TELEPHONES.—Since the 17th inst. the subscribers to the Paris telephones have been able to communicate with the Brussels centre up to midnight.

BERLIN, 24TH MARCH, 1890.

IRON.—Though the demand for iron is considerably below what it was at the beginning of the year, the tone of the market continues strong. Silesian bars maintain their price firmly at 210s. a ton. That this price will be upheld throughout the summer months seems pretty certain, but a further advance is not probable. Great activity prevails in the foundries. The production of pig iron in Germany, including Luxemburg, in the second month of the current year amounted to 362,026 tons, against 374,066 tons in the first month and 334,912 tons in February of 1889. The total production in the two months of 1890 amounted to 736,092 tons, against 702,023 tons in the corresponding period of last year.

FLAX AND YARNS.—There is a growing activity in the market for flax and yarns. At Trautenau the demand for tow and linen yarns is very brisk. The latter are hardly procurable for prompt delivery. A late report from Bielefeld describes the market as animated, yarns being in strong demand at prices a little above those of a week ago. As the cost of production has considerably increased of late, spinners are compelled to advance their rates.

THE PROPOSED COAL SYNDICATE.—The attempt to include the fiscal mines of Upper Silesia in the projected syndicate of colliery owners and coal merchants has failed. As the output of these mines forms fully one-third of the total production of the Upper Silesian coal-field, the scheme may be regarded as having fallen through.

SOAPMAKERS' CONGRESS.—An International Congress of Soapmakers is to be held in Stuttgart from the 16th to the 18th of April inclusive. During the time of the Congress there will be an exhibition of soap goods, as well as machines, tools, and utensils used in the manufacture of soap.

STERILISED MILK.—A share company, with a considerable working capital, has been floated here to work a patent for what is called the "sterilisation" of milk, that is, the destruction of the bacteria, through which certain diseases, notably typhoid fever, are spread. The milk in bottles is subjected to heat by means of a jet or current of steam at a temperature of 215° Fahr. Heat so applied has, it is said, no effect in changing the colour or taste of the milk. The stoppers are put into the bottles before the latter are removed from the steam. Care is taken to fill the bottles quite full to prevent a churning action during transport. Thus prepared, the milk will be sold retail by the ordinary milkmen at the price of 0 25 mark per litre. Arrangements have already been made with the Berlin milkmen for this purpose. It is said that the municipal authorities will specially favour the trade in sterilised milk with a view to promote its use among the general public.

DWELLINGS FOR OPERATIVES.—M. Krupp, of Essen, has recently given a sum of 500,000 marks as a fund out of which advances may be made to workmen who are desirous of buying dwelling-houses. He has also established a school of housekeeping for the benefit of the daughters of his workmen.

VIENNA, 24TH MARCH 1890.

THE COAL MARKET.—The market is without any change, and continues very firm. It is as much as the producers can do to keep pace with the demand. The Dux-Bodenbach Railway has already this year forwarded 160,000 tons more than during the same period of 1889. The two coal railroads, Dux-Bodenbach and Prague-Dux, each week show a greater increase of income. The Salgo-Tarjan Coal Company produced last year more than 600,000 tons, and made a clear profit of 432,000fl., which enables a dividend of 20 per cent. to be paid. The best orders for Bohemian brown coal come from Saxony. From the 1st of January to the 8th of March the Saxony State railways forwarded 1,702,000 tons of coal, 790,000 tons of which came from the Western Bohemian territory. Nearly 47 per cent. of all the Saxony coal traffic comes from Bohemia. The average has been 60,000 tons of brown coals per week from Bohemia to Saxony, but now the weekly export amounts to 80,000 tons.

THE IRON MARKET.—In the home iron market the influence of the English market is not yet visible. The brisk demand for pig iron is still steadily increasing, and cannot be satisfied, as there are no stocks. The works have orders for nearly the whole of the year. Refined iron has a good sale. The favourable condition of the market may be seen from the high prices of the shares of the public companies. The 3,000 shares of Sigl's locomotive manufactory, which remained in possession of the State since the fall of the ancient establishment, have recently been bought by the Credit Bank for a sum of 753,000fl. The condition of trade during last year is signified by higher dividends everywhere. The Pilsen Machine and Waggon Company is paying a dividend of 5 per cent. In general, waggon companies have the best of business. A few days ago Mr. Ringhoffer, of Smichow, received an order from the Bustehrad railway for 760 coal trucks and 11 tenders. The Simmeringer Maschinenfabrik have received an order from the State railways for some goods cars.

RAILWAYS.—During the year 1889 763 kilometres of new railways were opened for traffic in Austria-Hungary. Of these new lines 306 kilometres were in Austria, and 467 in Hungary. Most enterprise has been shown by the State Railways and the Northern Railway. Most of the new lines are only of local importance.

ELECTRICAL ENGINEERING.—The scheme is now settled for the construction of the electric railway between Baden and Vöslau. The contract is in the hands of Messrs. Siemens & Halske, of Berlin, and the work will be on their overhead wire system.—At a meeting of the Vienna and Brünn Telegraph and Telephone Company, held last week, it was announced that the total number of subscribers had increased from 1,317 at the end of 1888 to 1,776 at the end of 1889, and that already during the current year 250 new stations had been established. The directors also reported a very substantial profit.

BRUSSELS, 25TH MARCH, 1890.

THE COAL MARKET.—The condition of the coal market does not change, though the state is extremely sensitives The rumours of strikes in Germany and France and the recent labour troubles in England have given rise to hope. for better times in the Belgian centres. To lower the prices of fuel would, of course, be contrary to the desires of exporters, but if the prices do not slacken a little it is feared that the manufacture of iron and steel in all branches will suffer considerably. *Fines demi-grasses* are quoted at from 15fr. to 18fr., and nuts for rolling mills are firm at 18fr. The sorts for sugar works are at 20fr. Domestic coal at the pit, which has shown some activity lately, remains at from 20fr. to 22fr. Coking coal maintains its price of 22fr. to 23fr. for good qualities, and the minimum for coke is still 35fr. The Administration of the State Railways will proceed to grant contracts for the supply of 75 lots of 2,000 tons each of coal for use on locomotives.

THE IRON MARKET.—There is not much to report of the iron market. The buyers are still expecting that circumstances will arise which will prove more favourable to them, but all the same many of the products in manufactured iron are in good demand. In spite of the slowness of the market the prices are held firmly. If, however, the present condition of things is prolonged for any length of time, the manufacturers will experience some difficulty in obtaining replacing orders at the official rates of the iron syndicate. The raw materials continue to be expensive, and the price of fuel especially is out of all proportion with that of iron. The State railways are asking for tenders, to be sent in by the 2nd prox., for the supply of 2,500 tons of steel rails 52 kilogs. per metre.

THE GLASS TRADE.—The glass trade could manage with much more animation than is the case at present. The production has been decidedly raised lately, though perhaps to a greater extent than the demand. The prices are bound to be high on account of the cost of fuel. The Glass Association will meet this week to discuss and probably to settle definitely the statutes drawn up by the commission for the regulation of the trade with the United States. In plate glass the situation continues to be very good. The cost of raw materials has made itself felt here also, but the margin of profit is still large enough to satisfy the majority of manufacturers.

DÜSSELDORF, 25TH MARCH, 1890.

COAL.—The situation of the coal trade in this locality is significantly indicated by the fact that for a contract of 10,000 tons required by the railway authorities for delivery in April, only 5,700 tons were offered. The daily output of the pits is now about 108,000 tons. The present strong demand, which is in part the result of the measures taken by consumers to protect themselves against another interruption of the output, is not likely to continue many weeks longer, for the stocking is nearly completed, and business in the iron markets is falling off. There is no diminution of the agitation among the miners; indeed, the success of the English miners has given fresh impetus to the movement here.

IRON.—There has been a little more life in the market for pig iron during the last week, and prices have been firmer. The stimulant has been the increased cost of coal in England. Business in finished iron and steel has, however, shown no improvement. Joists are more inquired after; but in most other classes of iron goods the volume of business now being transacted is very appreciably less than it was a few weeks ago. The export trade is slack, the demand growing more languid week by week. Exaggerated reports of the falling off in the iron markets are being circulated for Stock Exchange purposes; but that they contain a large proportion of truth no unbiassed observer will deny. The American Institute of Mining Engineers has invited the members of the "Vereindeutscher Eisenhütteleute" to attend its meeting in Pittsburgh in October.

THE MILITARY EXHIBITION.—The Military Exhibition to be held at Cologne promises to be a great success. Upwards of 400 applications for space have been already received. The limit of time for receiving such applications expires with the current month. The scope of the Exhibition covers every branch of the military service. Some of the exhibits will be of a very instructive character. Thus we are to have a carefully arranged collection of rifles and field guns illustrating the progress made in the last twenty-five years. The Metal Cartridge Works Company at Karlsruhe, is preparing an interesting exhibit of its manufactures.

LILLE, 25TH MARCH, 1890.

IRON.—The iron market is moderately active and firmer in tone, but there is not much buying forward. Numerous small orders are being placed for prompt delivery. Generally consumers avoid dealings for which the necessity is not urgent, being persuaded that prices cannot long be maintained at their present level. The manufacturers, on the other hand, affect to believe that no relapse is possible, because the cost of the raw materials cannot be reduced for at least many months to come. As the building season is now commencing, a brisker demand is expected for joists. For the moment, the market is unusually quiet in that class of iron goods. Export orders are still coming to hand in considerable abundance.

Digitized by Google

TEXTILE MANUFACTURES.—The three last weeks of February and the first two weeks of March have been marked by a degree of activity in the market for linen goods considerably above the average for that time of the year. This activity has been maintained throughout the last week, and the tendency of the market is still good. The Roubaix woollen goods trade continues slack. In the raw wool market prices have given way. This decline is, however, wholly the effect of speculative operations. The state of the tulle trade at Calais is disappointing. A few months back everybody believed that the spring of 1890 would bring a great revival, and certainly there seemed to be good grounds for this belief. But the event has not fulfilled the hopes entertained. The season generally has been slack, and there is not much prospect of improvement. The tone of affairs in the tulle industry is therefore somewhat gloomy.

FLAX AND YARNS.—The market for flax grows stronger. The demand for home-grown steadily increases, and as there is not much on offer the price keeps up. Business in Russian has fallen off considerably. First-class Riga tows are in good demand, but there is not much doing in other sorts. Fine linen yarns are much inquired after. In the coarser numbers business is somewhat slack. For jute yarns the market continues active at full prices.

AMSTERDAM, 24TH MARCH, 1890.

THE ROYAL MACHINE WORKS.—The Royal Machinery Factory, an old-established and once prosperous concern at Amsterdam, has fallen upon evil days. Its president last week told the shareholders that the previous losses have not been made good in 1889, but, on the contrary, have been heavily increased. The company is losing over some completed contracts, whilst the profit on others, upon which it is still engaged, is still doubtful. The meeting of shareholders resolved to petition the Courts for a suspension of payments as a protection to the creditors. This means virtually a compulsory winding up, a result which must be regretted, because, on the one hand, it will throw thousands of mechanics out of employment, and on the other will bring to a close one of the largest machine works of Holland.

TRAMWAYS IN ROTTERDAM.—From the report of the directors upon the results of working of the Rotterdam Tramway Company, which enjoys a monopoly, it appears that the lines of the company have a total length of 24 kilometres. The company owns 116 cars, with accommodation for 3,728 people. In 1889 the company had 398 horses, and carried 5,961,050 travellers, who paid 446,000 guilders, or nearly £40,000.

STRIKES.—The strike among the stevedores and boatmen of Amsterdam still continues. Messrs. Burns and Tillett are coming from London to speak at meetings of the strikers. An extensive strike is now in progress at the large cotton mills of the company of Messrs. Ter Kuile at Enschede, the ostensible reason for this strike being the fining of two operatives who would not obey orders. The weaving factory of Messrs. Van der Weyll is also at a standstill, and the strike is rapidly extending. Thousands of artisans are idle. The authorities keep the Municipal Guard under arms for fear of disturbances.

THE WEST INDIAN MAIL SERVICE.—The Royal West Indian Mail Packet Company has done well in 1889. In twelve monthly journeys out and as many back the company has made a profit of nearly £20,000, and, after allowing £6,000 odd for depreciation, the directors propose a dividend of 6½ per cent. on the ordinary shares.

COPENHAGEN, 22ND MARCH, 1890.

INDUSTRIES IN SWEDEN.—The advances in Swedish industries are shown by the statistics of last year's exports. One of the most striking examples is wood pulp; the export of this article has been:—

25,630,000 kilogs.	in 1886	38,484,000 kilogs.	in 1888
28,578,000 „	1887	52,035,000 „	1889

There is a corresponding movement in the export of paper, although the rate of increase is a much smaller one; a still further growth of this industry may be confidently reckoned upon. The exports for the last four years were:—

8,596,000 kilogs.	in 1886	11,440,000 kilogs.	in 1888
9,802,000 „	1887	11,540,000 „	1889

In dairy produce Sweden has by no means managed to keep pace with Denmark; the export of butter was, in fact, slightly smaller last year than during 1888. The figures respectively were: 14,734,000 kilogs. in 1889, and 14,809,000 kilogs. in 1888. With regard to cheese the export has been on the decline for the last three years. Bacon has become a very important industry in Denmark and Sweden; from the latter country the exports during the last four years were:—

1,588,000 kilogs.	in 1886	4,744,000 kilogs.	in 1888
3,124,000 „	1887	7,347,000 „	1889

The exports of textile manufactures are steadily increasing, and this industry is doing well in Sweden, most of the manufactories being fully employed. In the mining and metal trades an improvement is manifest in almost all the branches. The export of iron ore has become a very important one and will no doubt continue to increase, especially when the Norrbotter railways are completed.

The exports of iron ore for the last four years were:—

19,288,000 kilogs.	in 1886	117,350,000 kilogs.	in 1888
41,985,000 „	1887	118,573,000 „	1889

Of iron the exports of the more important descriptions were as follows:—

		1888.	1889.
Pig iron	kilogs.	49,095,000	79,175,000
Ingots	„	6,459,000	8,530,000
Blooms	„	14,536,000	15,596,000
Bars (hammered or rolled)	„	187,775,000	200,244,000
Plates „ „	„	5,780,000	5,717,000

MORE BREWERIES.—Another large brewery company has been formed in Stockholm, under the name of "Stora Bryggeriet," with a capital of about 2,000,000kr. A site of 441,624 square feet has been secured, and the erection of buildings will be commenced shortly. The establishment is to be fitted with everything "up to date" in the way of practical and scientific appliances. The capacity is estimated at 100,000 hectolitres annually, but as a commencement it is not intended to brew more than 50,000 hectolitres per annum. The newly-formed Fortuna Brewery Company at Christiania held a meeting a week or two ago, when the chairman informed them that it had not been possible to find a suitable and convenient site, wherefore negotiations had been entered upon with the proprietors of Eger & Co.'s brewery with a view of purchasing this establishment for the Fortuna Company. This brewery would then be gradually extended, and in every respect brought up to the mark. The Fortuna Company would thus have one competitor less, would acquire a going concern, and would be able to commence operations at once instead of waiting till a new brewery had been erected. The proposal was unanimously carried. The price for Eger & Co.'s brewery is 660,000kr.—In Copenhagen the building of a kind of co-operative brewery is understood to have been decided upon, mostly intended for the working classes.

MADRID, 24TH MARCH, 1890.

THE WATER SUPPLY OF BARCELONA.—A considerable increase of the water supply of Barcelona is contemplated, and has every chance of being carried out vigorously.

RAILWAYS IN VIZCAY.—The good commercial results of the railways in the Vizcayan provinces, under the control of local companies at Bilbao, have given a great impulse to the demands for concessions, and within the next two or three years that province will be as well provided with railways as any part of England or Belgium. It is no wonder that this is the case, since the Bilbao and Durango line yielded 17 per cent. interest on the shares last year. Another instance of the excellent business in railways is the line from Bilbao to Portugalete, whose 500fr. shares are sold at 1,250fr.

TINPLATES.—A severe battle is being fought between makers of tinplates and the Galician and Asturian vendors of preserved meats, fruits, &c. There is a law in Spain which authorises the free importation of certain articles which may be worked upon and then re-exported. The makers of preserved foods have asked the Government to include tinplates on the list. This the tinplate makers oppose, and it is very doubtful what will be the final decision. So far there is only one maker of tinplates in the country—Messrs. Goitia & Co., of Bilbao—who make a first-rate quality from Siemens-Martin steel slabs. There is still an opening in Asturias for the manufacture of tinplates at a much lower price.

HORNACHUELOS COAL BASIN.—Señor Ingunza has lately made a report on the Hornachuelos coal basin in the province of Cordova, half way between Peñarroya and Guadalcanal. Although a comparatively small mine, the engineer considers that it would be easy to establish workings to raise 200,000 tons per annum for a period of twenty years without going to any considerable depth. The excellent quality of these coals makes it very desirable that they should be worked, but there is very little chance that this can be done at a profit before the southern lines of railways follow the example of the large northern system as regards reducing the rates of carriage. The high prices prevailing in England would soon lead to the exclusive use of native coals, but a hindrance to this is that many coal mines are in the hands of the railway companies, and these prefer to make large profits on small quantities, and they consider it to their interest to keep the prices as high as practicable in comparison with the cost of English coals.

NEW YORK, 15TH MARCH, 1890.

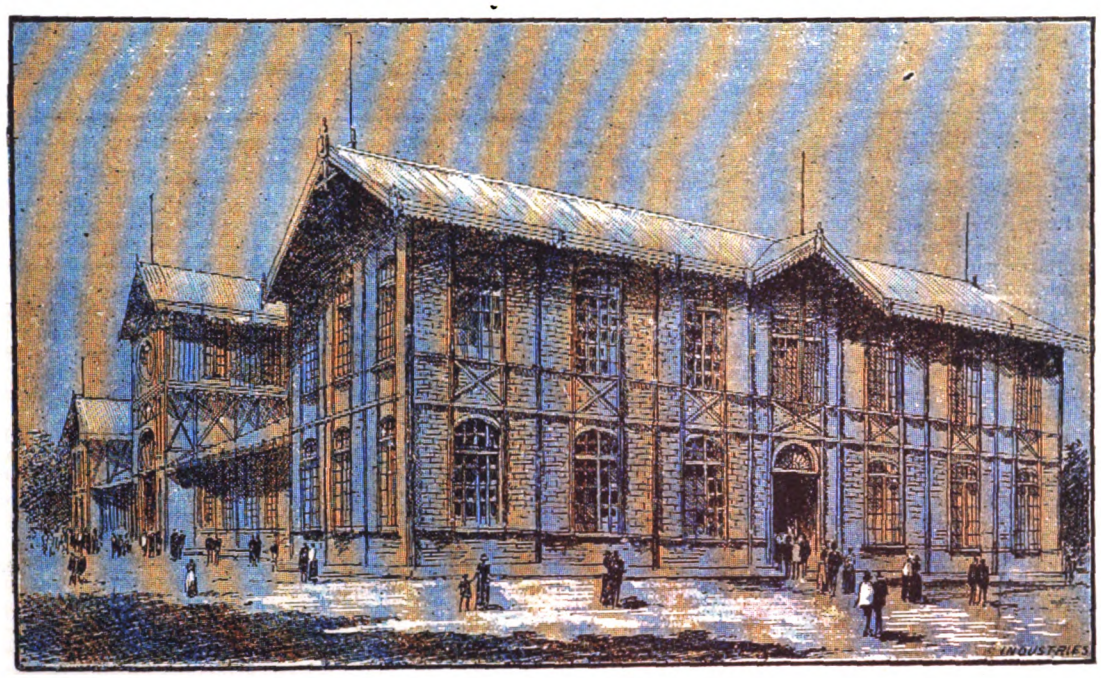
GRAVITY ROAD UNDER EAST RIVER.—On the 5th inst. the contract for the construction of the tunnel of the East River Railway Company was let in New York to the American Tunnel Construction Company. By the terms of the contract the surveys and drawings are to be made within sixty days. Steps are then to be taken to secure the necessary authority for the cities of New York and Brooklyn, and the president of the company expects to have the railroad in full running order within two years after these privileges are obtained. It is proposed to connect with the Manhattan Elevated Road on Broome Street, New York. The tunnel train will run on an elevated track until within a block of the river, when a plunge will be made into the tunnel; the car will gain a momentum sufficient to carry it up an incline on the Brooklyn side, where before it stops it will clutch a cable, and this cable will draw it to the station platform on South Sixth Street. The car will run back the same way. The whole time of the trip in the tunnel is estimated at fifty-six seconds.

PROSPECTIVE STRIKE.—The miners and cokers of the Fort Hill and Paull Works of Mr. W. J. Rainey have decided to come out on a strike, but have deferred doing so until the employés of Rainey's other plant agree to join them. If they are joined by the Moyer men they claim they can force Rainey to sign the scale and reinstate a discharged man which is the cause of the disaffection. This means a strike of over 800 men, as the men of the three works will join forces. Rainey is the only operator in the district who has not signed the labour contract, and a very small opportunity has been afforded his men to organise, and if any of them attempt further organisation they will be discharged.

SMELTING TRUST.—The *Chicago Herald* states that, with the exception of five companies, all the refining and smelting companies of the United States have formed a trust with a capital of $25,000,000, of which three-fifths is to be common stock and two-fifths preferred. The common stock is to be used for the purchase of the properties that go into the new organisation, while the preferred stock is to be used to carry on their business. The chief object of the smelters, it is said, is to place their interests beyond the control of the late combination.

THE SOCIAL SIDE OF THE ELECTRIC STREET RAILWAY.—At a meeting of the New York Electrical Society, on the 12th inst., Mr. T. Commerford Martin, editor of the *Electrical Engineer* of New York, gave an interesting lecture upon this subject. The effect of the stables which house the 15,000 horses engaged in hauling the street cars of this city upon the public health was a strong point in favour of electricity. The effect of the electric railway upon the physique and morale of the employés compared very favourably with the effect of the horse-cars. One certainly could not expect a man who spends the day with his nose near the tail of a horse to realise a very high ideal of life and duty, especially when the whole of his work is done under conditions exhausting alike to temper and physique. With the electric car the matter is not one of brawn and muscle, but of average intelligence and ordinary readiness of decision. From a humane point of view, electricity was destined to do a great work, for the straining and struggling of tired horses on slippery stones would soon be a thing of the past.

THE "ELECTRICAL ENGINEER" OF NEW YORK.—A change is coming over the aspect of the New York *Electrical Engineer*. Instead of coming out monthly, it will in future appear every week. Messrs. T. Commerford Martin and Joseph Wetzler, well known so far as the able editors of the enterprising *Electrical World*, have now become joint editors of the *Electrical Engineer*. The rapid development of electrical engineering in the United States is noticeable in its literature.



PHILADELPHIA, MARCH 14TH, 1890.

STREET RAILWAY TRANSACTION.—By a transaction recently completed a company, known as the Philadelphia Street Car Syndicate, has obtained possession of a controlling interest in the Twenty-third Street Cross-town Railroad Company of New York. The syndicate purchased 3,300 shares out of the 6,000 of the company's stock, mostly in small lots, from 150 different holders. The road, with the Blecker Street and associated lines, will be hereafter run in harmony with the Broadway and other lines already controlled by the syndicate. The company has been paying 10 per cent. The syndicate offered 17 per cent. rental, but was prevented from securing a lease by a clique which had control of a minority of the stock, a two-thirds vote being necessary to lease the line. By buying up a majority of the small holders the control of the line was secured without the lease.

PENNSYLVANIA RAILROAD.—The annual report of the Pennsylvania Railroad Company for 1889 shows the gross earnings for the whole system to have been $122,917,337, or $6,408,044 larger than in 1888; the expenses were $83,811,127, or $3,073,792 greater than in 1888; and the net earnings were $39,106,209, an increase of $3,334,252 over the previous year. These are the largest earnings in the history of the company; this is a very remarkable fact, for during the whole month of June, owing to the Johnstown flood, the main line was partially closed to traffic. The number of tons of freight carried was 122,164,118, against 110,843,874 in 1888, and the number of passengers was 78,126,957, an increase of 4,126,871. The average earnings per ton per mile for freight were ·686c., against ·693c. in 1888, but the cost of transportation was ·473c. in 1889, against ·482c. in 1888, and the profit ·213c., against ·211c. last year. The average earnings for each passenger per mile were 2·082c., against 2·092c., and the cost of transportation was 1·527c., against 1·543c. in 1888, and the profit was ·555c., against ·549c. in 1888. The average distance travelled by each passenger was 18·1 against 17·9 miles in 1888. Dividends of 5 per cent. were paid. The total amount expended for flood repairs to December 31st was $3,475,425, and a considerable sum remains to be spent; this does not include the loss from suspension of traffic. The improvements under consideration include a locomotive shop at Altoona, a bridge over the Ohio river at Pittsburgh, the construction of a cut-off from Downington to a point near Trenton, a new line from Downington to Lancaster, important improvements on the New York water front, and large expenditures to avoid grade crossings in this and other cities.

EXHIBITION AT BUENOS AYRES, 1890.

EXHIBITION AT BUENOS AYRES, 1890.

The Société Rurale Argentine will open its second Exhibition at Buenos Ayres next month. The Exhibition will be divided into three sections, namely:—

Section 1.—Cattle, domestic animals, and fowls.
Section 2.—Agricultural machinery and implements.
Section 3.—Products of agriculture.

Sections 1 and 2 are open for all countries, but Section 3 will be devoted solely to national productions. As regards Section 2, it has been decided that no machine in use before the year 1886 shall be available for exhibition. The jury will only admit such machines as have been invented or fundamentally modified since that time. In connection with the Exhibition four prizes are to be offered, amounting to 2,500 piastres each, for the best essay on each of the following subjects:—

(1) The exportation of meat.
(2) The present and future condition of agriculture in the Argentine Republic.
(3) The national industry of wine growing.
(4) The present and future condition of the sugar industry in the Argentine Republic.

We give above an illustration of the grand central pavilion forming part of the Exhibition buildings. We are indebted to our contemporary, *La Revue Illustrée du Rio de la Plata*, for the illustration.

THE INSTITUTION OF CIVIL ENGINEERS.

At the sixteenth ordinary meeting of the Session, on Tuesday, the 18th inst., Sir John Coode, K.C.M.G., President, in the chair, the paper read was on the "Lough Erne Drainage," by Mr. James Price, Jun., M.Inst.C.E.

The physical characteristics of the Lough Erne district, comprising 1,056,160 acres, were first described, and the various schemes proposed at different times for effecting the drainage of the district, without lowering the navigation level, were referred to. The works which had been carried out were designed by Mr. James Price, Sen., M.Inst.C.E., in 1878, and consisted in cutting a channel through a rocky barrier at Belleek, on the River Erne, below the Lower Lough Erne, controlling the discharge through this channel by large sluice-gates, and improving the channels above Belleek and between the two lakes. The sluice-gates, when closed, retained the water at its normal summer level; whilst the raising of the gates, on the first intimation of heavy rain commencing in the upper districts, enabled the large water-surface of 27,643 acres on the lower lake, and 9,453 acres on the upper lake, to be drawn down 6in., so as to make provision for a flood in anticipation of its arrival, and thus prevent the flooding of the adjacent lands. The works were commenced in 1882, at the lower end, and the sluices were completed in September, 1883, the upper works being subsequently carried out. The channel at Belleek was excavated under the protection of clay dams, and the upper channels were mainly improved by dredging. The four sluice-gates, designed by Mr. F. G. M. Stoney, M.Inst.C.E., sliding against a train of 8in. live rollers, were 29ft. 2in. wide and 14½ft. high, and capable of being raised 9ft., and had been working most satisfactorily for the last six years. Each gate weighed 13 tons, and could be easily raised by one man to its full height in forty-five minutes, or the four gates could be lifted simultaneously by a turbine in half an hour. Their total cost, exclusive of masonry, was £4,000. Large compensation had to be paid for anticipated injury to the fishery rights, though the works had actually improved the salmon fishery. The total cost of the works was £180,000, of which £30,000 was for navigation and £150,000 for drainage. The author was the resident engineer for the whole of the works, and the lower works were carried out under his supervision; whilst the works between the lakes, and in the upper lake, were executed by contract. Observations of the rainfall, lake levels, and sluice discharges, for the years 1885–88, had been put in the form of a diagram. Allowance had been made for a discharge of 600,000 cubic feet per minute, of which 400,000 cubic feet had to be provided for by enlargements of the channels; but it appeared from the diagrams that, owing to the power of anticipating a flood by means of the sluices, a discharge of 500,000 cubic feet per minute would have sufficed to prevent flooding, without unduly lowering the navigation level of the lakes. The Erne diagrams showed how little the storage in the lakes affected the summer flow, and indicated that the great store for the summer yield of a river was the ground-water. The general effect of the Erne drainage had been to render the water level of the lakes more uniform—higher in summer and lower in winter. The bad effects of the flooding, during a wet summer, of the extensive flat lands bordering Lough Erne, which extended in an unbroken sheet of water for 50 miles, were not confined to the loss of the year's crop of grass, for the decayed grass affected the next year's hay crop; whilst large tracts of undrained land, by exposing large surfaces of spongy grass to evaporation, chilled the air, preventing or delaying the ripening of corn; and the damp chilled air, mixed with the products of decaying vegetation, fostered disease. In some cases occasional floooding might be beneficial to land, owing to the manuring qualities of the flood deposits, and sluices enabled such flooding of flat lands to be effected for short periods at suitable seasons.

The author advocated the following general principles in designing drainage works: (1) That the cross section of the enlarged channels should be hyperbolic instead of trapezoidal, increasing the discharge in proportion to the section, obviating slips by flattened slopes next the land, facilitating dredging and confining the low-water channel so that the sides could be cleaned; (2) that the channels should be given a fall of only 1ft. or 2ft. per mile, with embankments and back drains where necessary, and accumulating any excess of fall at certain points where the discharge might be effected along paved channels. The extension of arterial drainage in Ireland would render large areas of land available, and would raise the mean summer temperature, which at present was only 58° Fahr. Amended laws, however, would be required for carrying out any large drainage works in the future, and the initiation of the schemes could no longer be left to the landowners, who, under their altered conditions of tenure, had lost their former interest in the improvement of their estates.

THE COAL FIELDS OF THE TRANSVAAL.

(From a Johannesburg Correspondent.)

The coal fields of the Transvaal are perhaps much more extensive than most readers would imagine, both as regards area and mass, and the amount of solid work and money which have been and are being put into the coal industry will probably surprise many people. Avoiding figures as much as possible, we will endeavour to give a brief outline of the position and prospects of this rapidly rising industry.

We will begin, then, at Boksburg, which up to date is the nearest source of coal to Johannesburg, being only some fourteen miles distant. Over a year ago we were informed that it was more than probable that coal would be found within five miles of the town, but owing to this idea being "jumped," the verification has never been put to the test. We will take as our starting point the mine of the Boksburg Coal Company, the property of which is now absorbed by the Transvaal Coal Trust Company. In this mine we have a seam of coal from 5ft. to 10ft. in thickness, at a depth of 60ft., roughly speaking. The coal, however, appears to be "drift" coal, and, as may be expected, not of the best quality, carrying as it does a rather large proportion of shale. The development of this mine has been well thought out—timbering, tram-lines, and other facilities having from time to time been added as required to the underground workings, while the head-gear and hauling-gear are as good as will be found at present on any mine in the Rand Fields. But in the Boksburg district, which is no exception to the general rule, we have varying qualities of coal, and find small companies and even private individuals able to hold their own against companies with a good capital and agents in Johannesburg, simply by having a better quality of coal, as is seen by the Black Diamond property and on one or two lesser blocks.

Leaving Boksburg the next centre reached is Brakpan, where perhaps one of the best planned mines in these coal fields is to be found, due to the exertion of Mr. Newby. The coal at Brakpan is of a better quality than that at Boksburg, yet inferior to that found further east. The mode of working this mine is so conducted as to make it a really good property in spite of the second rate quality of the coal. From Brakpan one or two doubtful "vleis" are crossed, one being the famous Bronkhorst Spruit, the district being the Wilge River, about thirty miles beyond Brakfontein and fifty miles from Johannesburg. Several companies are at work in this district, including the Anglo-African, the Holfontein, Excelsior, Klipfontein, Greville, and others. Some of these companies are already absorbed by the Transvaal Coal Trust Company, others are worked by private companies and individuals, some of which pay excellent returns; one is yielding over £3,000 per annum profit, which certainly is not bad interest for the capital expended, when the amount of opposition is considered. The present systematic operations in the Excelsior mine stand in strong contrast to the old workings now abandoned in the same mine, the output of coal from a 14ft. seam being worked by drive and cross-cuts of only 6ft. by 7ft. These give ample room for easy working without endangering the "falling in" of ground by cutting out huge caverns and having no thought of safety or drainage, two essential points which are carefully attended to in the new workings. The average output of this mine is twenty waggons, or 80 tons, per day, and this without any strain upon the staff of five white men and about seventy Kaffirs, and but for the difficulty of transport this amount could be largely and easily augmented by the present staff. One remarkable feature of this property is that no machinery is used on any part of the mine, hauling being done by mules, and pumping superseded by natural drainage. The quality of Wilge River coal is superior to that of Brakpan and Boksburg, and finds a ready market. About twelve companies are at work in Wilge River district. The Greville Company (one of the latest) are almost down to the coal in their shaft. The quality of this coal has been already tried and proved from borings, and found to be excellent for steam and gas purposes. In this district also several smaller mines are carried on by private individuals, and are made to pay their way. From Wilge River to Steen Kole Spruit, the next centre, is about twenty miles. Many pans, appearing almost like craters, are passed along a rather heavy road due to loose sand. The Johannesburg Gas Company have recently taken over a property in this district to supply their

Digitized by Google

works and to be independent of outsiders. There are also several other companies turning out coal of a better quality in most cases than that in the former districts, yet inferior to the next area—Olifants River—chiefly from the fact that the coal from this district is non-coking. This is a rather significant point, as all the districts mentioned so far have non-coking coal, which is an all important point in connection with gas-making. This coal is in good demand for steam purposes. The next and perhaps the most important centre is the Olifants River district, distant from Johannesburg about eighty miles, and from the last-named centre about ten miles. The opening of these fields was carried on in a very primitive manner, as until quite recently the whole of the coal was taken from the splendid seam which in many cases outcrops, or rather is exposed in the bed of the river. This is undoubtedly the true carboniferous formation—a gentle undulating country on the surface, with a true and almost undisturbed sandstone, along with stratas of true shale, give a sort of introduction to the coal. Several large properties are being worked in this area, and but for the inconvenience of transport, this would undoubtedly surpass many of the nearer districts which possess inferior coal but easier transport. Shafts are now being sunk, and most of the properties are taken up and being worked. Want of accommodation is much felt here, and but for the hospitality of people living in the district visitors to this locality would fare badly.

Notices of Meetings.

THIS WEEK.

INSTITUTE OF MARINE ENGINEERS.—Saturday, March 29th. Annual General Meeting. 7.30. Business: Reports, Election of Office Bearers and Council for ensuing year.

NEXT WEEK.

CHEMICAL SOCIETY.—Thursday, April 3rd, at 8 p.m. "Note on the Hydrosulphides." by G. H. Picton.

PRICES CURRENT, 26TH MARCH, 1890.

Quotations at per ton, unless otherwise specified.

ANGLES, PLATES, BARS.

Messrs. G. Bailey Toms & Co., London, quote as follows:—

„	English Ingots	95	0	0	„	.....		

Messrs. Carrick & Brockbank, Manchester, report as follows:—

COPPER: A large decrease in stocks is reported during the first fortnight in March, owing to heavy deliveries and the smal charters from Chili. The figures are: Decrease for first fortnight March, 3,232 tons; total visible supply 15th March, 91,920 ons. This decrease, together with the settlement of the coal strike, has helped to improve prices of Chili bars, which have advanced 30s. per ton during the week, to-day's quotations being £48 12s. 6d. to £48 17s. 6d. cash, as compared with £47 2s. 6d. to £47 10s. on the 19th. Manufactured, however, continues very quiet, with small demand. Prices to-day are £61 sheets and £64 bottoms.

TIN: This market remains inactive, with but little variation in prices. The continued unsatisfactory condition of the tinplate trade has a decidedly unfavourable influence on this metal.

LEAD: Values are a shade firmer, but with small business doing.

SPELTER: Market keeps very dull, owing to the quietness of the galvanising trade, and quotations are unchanged.

Messrs. S. W. Royse & Co., Manchester, report as follows:—

CHEMICALS: With the termination of the coal strike matters have become more settled in the chemical trade. Soda ash, caustic soda, and soda crystals continue scarce, and high figures are paid for prompt delivery. There is only a comparatively moderate inquiry for bleaching powder, and prices are likely to be easier. Carbolic acids, crude and crystal, are very dull, but liquid is firmer. Benzoles weak. Sulphate of copper is scarce on spot, and is less freely offered forward. Tartaric acid has advanced strongly, and oxalic acid is also dearer.

FOREIGN TELEGRAPHIC ADVICES.

(From our own Correspondents.)

PARIS, March 27th.—*Iron.*—There is not much doing in the iron market here; nevertheless, bars and joists are firm at 160s. for the former and 164s. for the latter. Business is very active in the Haute-Marne, but quiet in the Nord. Prices are maintained at 160s. for No. 2 bars in the Ardennes. The Longwy syndicate is offering forge pig to Belgian consumers at 65s. 3d. a ton delivered.

Metals.—The speculative holders of copper warrants find it hard to maintain the price of Chili bars at £52. Consumers buy only for the present. Tin is a shade better: Banca, £100; Straits, £97. Lead has declined to £13 at Havre, £13 6s. Paris. Spelter is steady at last week's prices: Silesian, £24 at Havre. There is, however, but little demand.

BERLIN, March 27th.—*Bourse.*—The market for industrial securities is unsteady. A large speculative business is being done in shares in collieries and iron and steel manufacturing companies; but investors having for the most part withdrawn from the market, of genuine business there is practically none. The prospect is regarded as uncertain. Industrial securities, too, are quoted too high to attract the investing public.

Iron.—The iron market has become firmer on receipt of more favourable reports from the Upper Silesian districts. Buyers are, however, not operating freely. There is a growing demand for building iron, but generally business is slack. Silesian bars cannot now be bought under 210s. a ton.

Metals.—The metal markets are lifeless, and prices tend in favour of buyers. Mansfeld refined copper is weak at £59 to £60. English brands, £56 to £57. Tin is with difficulty maintained at £100 to £101 for Banca. Lead is a little more inquired after: Clausthol refined very firm at £15 10s. to £16. Spelter shows a declining tendency: Silesian W. H. brand, £25 5s. to £26; ordinary, £25 to £25 10s.

BRESLAU, March 27th.—*Coal.*—Notwithstanding the milder weather, the market for coal loses none of its activity. The export demand continues strong. The production is barely sufficient to meet current requirements. Prices firm at 8s. to 9s. a ton for large and round coal, 7s. 3d. to 8s. for nuts, and 4s. 6d. to 5s. for small, at the pit bank. There is still an insufficient supply of coke.

Iron.—The production of pig iron is now being pressed to its utmost limits in anticipation of many of the hands employed about the blast furnaces being withdrawn for agricultural operations. Demand brisk. Market very active for bars, joists, and plates, and prices firm at last week's quotations. Founders are short of hands.

Metals.—The zinc market has scarcely changed during the last week. Business is dull, and the prices of spelter are a point lower. Some small lots have been sold at £22 to £22 10s., but these are exceptional prices. There is a moderately good market for lead.

DÜSSELDORF, March 27th.—*Coal.*—The tenders for 50,000 tons of unscreened coal and briquettes for the Cologne Railway show lowest prices for the former 14s. 6d., and for the latter 17s. to 18s. a ton. Relatively to last year's contracts this is a rise of 100 per cent. A small lot of coke was offered at 28s. to 29s. a ton. Delivery is to be made in May and June.

Iron.—The business of the iron has greatly fallen off in the last two or three days. Very few transactions are taking place in pig iron, some sorts of which are offered at lower prices. Rhenish-Westphalian forge, 91s.; Siegen forge, 90s.; foundry No. 1, 96s. to 98s. Finished iron and steel quieter, but active business in joists. Prices remain firm. Wire neglected.

CHARLEROI, March 27th.—*Coal.*—The high prices for coal are not only firmly maintained, but for some sorts have been further advanced. Consumers are now buying only for present requirements. Some offers to place a twelve-months' order for coke at the price of 24s. a ton have been refused. Sellers will not accept less than 28s.

Iron.—The situation of the iron market grows worse. There is now practically nothing doing, and nothing is to be expected till the cost of coal is reduced. Many manufacturers have ceased to work on Mondays. The tone of the market is depressed.

GHENT, March 27th.—*Flax and Yarns.*—The market is less abundantly supplied with home-grown flax, and as the demand continues strong, prices have an upward tendency. Russian produce is not much dealt in, but prices are firm. There is a steady current of business in yarns, the prices of which remain unchanged.

THE ELECTRICAL CONSTRUCTION CORPORATION have sent us a bundle of nicely-got-up sheets of prices of continuous current dynamos and storage batteries.

MESSRS. YARROW & CO., of Poplar, have in the course of construction six shallow-draught gunboats for the Portuguese Government, intended for use on the Zambesi. These are similar to those built by the above firm in the early part of last year, and in which Major Serpa Pinto made his recent expedition up that river, which has attracted so much attention.

PAPER MAKERS' DIRECTORY.—Messrs. Marchant, Singer, & Co., 47, St. Mary Axe, London, E.C., have issued a pocket edition of the "Directory of Paper Makers" for the present year. This little work, which is compact and neatly printed, contains an alphabetical list and a classified list of the paper and mill board makers of the United Kingdom, together with useful information relating to "water marks."

HOME INDUSTRIES.

LONDON 27TH MARCH, 1890.

THE MONEY MARKET.—A fairly sustained demand for loans has kept the money market rather harder lately. Several colonial loan operations have absorbed a considerable portion of the available supply. At the same time the general prospects of the market, as indicated by the exceptionally strong position of the Bank of England, and as reflected in the easy rates at which the Government has been able to raise money on Treasury Bills, has imparted an easy feeling to discount rates, which have given way, and are now about 2¼ per cent. In the stock markets speculation is well nigh dead, and business is, consequently, at a standstill. The cessation of anxiety about coal strikes had only a momentarily good effect on home railway stocks. Selling orders from Berlin, where the fall in coal and iron shares has rather shaken the Bourse, have depressed our market, for latterly the Germans have become large holders of some of the English and American securities. Thus the influence of Berlin selling has spread beyond our foreign department, which, indeed, is fairly firm, save in South American securities. Argentines are quite out of favour, not so much through fears of financial ruin in the Republic as from the expectation of a crisis at the next settlement on the Buenos Ayres Bourse. Nitrate railway shares, and with them all the "North" group of securities, have fallen on the prospect of the construction of a competing line through part of the nitrate country. Mining shares have experienced a sharp fall, South African gold shares being heavily sold. Miscellaneous and industrial securities are receiving very little attention.

COMPANIES.—The following companies have been registered since our last report:—The Peruvian Corporation, Ld., with a capital of £16,500,000, to acquire any property, rights, or claims in the Republic of Peru or elsewhere; The Black Lion Brewery Co., Ld., with a capital of £19,000; The Grass Valley Exploration Co., Ld., with a capital of £5,100, to acquire mines, &c., in California or elsewhere; Samuel Sutcliffe & Sons, Ld., with a capital of £45,000, to carry on the business of spinners, &c.

SPORTSMAN'S EXHIBITION.—The ninth annual Sportsman's Exhibition is to be held at the Agricultural Hall, Islington, from the 10th to the 18th April. The offices are at 43, New Oxford Street, W.C.

THE NAVY.—The "Minotaur," formerly flagship of the Channel Squadron, which has been refitted and repaired at Portsmouth at an estimated cost of £53,000, made a four hours' trial of her machinery on Friday last. The trial was successful, 4,800 horse-power having been developed by the engines and a speed of close upon 14 knots obtained. The Admiralty have issued orders for the construction of the new second-class cruiser "Brilliant" to be begun at Sheerness Dockyard. The "Brilliant" is the largest and most powerful ship ever ordered to be built at Sheerness Dockyard. The vessel is to be 300ft. in length, and 43ft. 8in. in breadth, with a mean load draught of 17ft. 6in. She is to have a displacement of 3,600 tons, and is to be fitted with triple expansion engines, which are to be capable of producing 9,000 horse-power under forced draught, with a speed of 19·75 knots on the measured mile, and 7,000 horse-power under natural draught, with a speed of 18·25 knots on the measured mile.

ELECTRIC LIGHTING IN PADDINGTON.—The other day a special meeting of the Paddington Vestry was held for the purpose of considering the question of the electric lighting in the parish, which had been considered by a committee of the vestry. Colonel H. C. Barchard proposed the adoption of the report, which recommended that the application of the Kensington and Knightsbridge Electric Lighting Company should be assented to. But if the vestry considered the draft regulations now being prepared by the Board of Trade to do away with the objections to the high-pressure supply system, then the committee were of opinion that the application of the Metropolitan Company might be considered. As the cost of lighting the streets with electricity would be very greatly in excess of gas, the committee did not feel justified in recommending it, though in the future, when the electric company's arrangements would be more matured, action could be taken for so doing with advantage. As the report met with much opposition, it was agreed to adjourn the further consideration of the matter.

ENGINEERING.—There are wanted for Finland 2,770 tons steel rails, 230 tons steel chairs, 20 tons fish plates, and 20 tons iron bolts and nuts for a short railway to be erected there. Information may be obtained from the Foreign Office.

MANCHESTER, 27TH MARCH, 1890.

THE IRON TRADE.—A somewhat indifferent feeling prevails in the local market, and buying is on a very small scale. There are still a number of contracts to run out, and most of the large users are not disposed to enter into new ones. Middlemen are anxiously endeavouring to obtain orders, and prices are offered below makers' rates without much success. In some cases a belief is expressed that the market will shortly revive, but until matters are more settled generally this is hardly likely. In the meantime engineers continue to be actively engaged, and they will soon be obliged to begin buying again. The finished iron makers are well occupied with old contracts, but are not receiving many new ones. The price of common bars is down to £8 per ton, at which price they are obtainable from merchants, makers quoting 5s. per ton more. Although the boiler making trade continues to be busy, steel plates are not being bought largely at present, as users expect a reduction of price.

THE COAL TRADE.—The strike of miners came to an end last week, and prices have resumed their normal level. Several mills were stopped for a short time, and high prices were paid for coal supplies. An attempt is to be made to form a joint scheme for fixing the wages in the future, Although it binds neither side to little more than the giving of prior notices, it is hoped that the extended period for discussion will permit of compromises being arrived at.

THE PAPER TRADE.—A conference of paper makers representing the various branches of the trade was held in Manchester on the 22nd inst. The workpeople have protested against the long hours worked in some mills, and have suggested that all mills should stop at 2 p.m. on Saturday, and not resume work before 6 a.m. on the following Monday. Generally the proposal was well received, but in order to allow of a fuller representation the meeting was adjourned for a fortnight.

THE LINEN AND JUTE TRADES.—It is extremely amusing to note the widely divergent character of the accounts given by manufacturers' agents as to the condition of the linen trade. On the whole, it may be said that producers are fairly busy, although prices are not generally satisfactory, owing to the perversity with which buyers profess to disregard the effect of the recent advances in wages, fuel, and other items which go to make up the total cost of production. There is a steady business passing in damasks, towels, and other varieties. Several special inquiries have been received of late for Continental makes of linens, but it is not an easy matter to meet with agents for the sale of these goods, as a considerable portion of the business is transacted direct. There is a fair demand for the coarse makes of Scotch goods, and a moderate inquiry for Dunfermline specialties. Jute fabrics are in active request, and linen threads are extensively called for.

A NEW SALT SCHEME.—A private Bill has been lodged in the House of Lords by a company called the Widnes Brine Supply Company, who propose to pump brine from wells at Wincham, near Northwich, and convey it by means of pipes to Widnes, where it is to be used in the manufacture of alkali. The brine is successfully used by many chemical manufacturers now, and the present scheme, if allowed, would probably be of great value to the Widnes manufacturers. It will, however, be strenuously opposed by the various authorities in Northwich, who claim that they will be subjected to all the inconveniences of subsidence, &c., without any of the compensations which arise from the manufacture of the salt in the neighbourhood. The Weaver Trustees, who act practically on behalf of the ratepayers of the county, will also strenuously oppose the new Bill, as they derive a large revenue from the carriage of salt, and their surplus profits go to relieve the county rate. Parliament has hitherto resisted any such scheme, and the strong opposition to the present proposal will probably lead to stringent compensation clauses, even if it is sanctioned.

GLASGOW, 27TH MARCH, 1890.

PIG IRON.—There is nothing new to report regarding the pig iron market. It is very difficult to reconcile all that is being said about the falling off in demand with the continued large deliveries ex store and the advance of 1s. per ton declared this week by the makers of Gartsherrie, Eglinton, and Carron. Now that we are entering upon the season of spring shipments there is very little prospect of any demand from the States or from Canada, but the Continent is buying pretty freely, and the Lancashire ports are likely to take a good deal of Scotch iron to make up for short supplies from Lincolnshire, where the scarcity of coal and coke has led to a restriction of the make. The advancing prices daily obtainable for Middlesbrough warrants have contributed much to the firmness of the market.

RAILWAYS.—The Town Council of Edinburgh has decided by a majority to oppose the Bill of the Caledonian Railway, by which powers are sought to construct a tunnel under Prince's Street, Edinburgh.

PROPOSED INDUSTRIAL EXHIBITION.—A proposal has just been brought forward for the promotion of a movement to hold an Industrial Exhibition in the East End of Glasgow.

THE NEW TUBE COMPANY.—The ordinary shares of Messrs. Andrew & James Stewart & Clydesdale, Limited, to which reference was made in this column last week, have been subscribed for three and a half times over, and the preference shares four times over.

EDINBURGH ELECTRICAL EXHIBITION.—The rate of insurance upon the buildings, mechanical and other exhibits, and pictures in the Exhibition at Edinburgh has been fixed at 42s. per cent. The buildings are making rapid progress towards completion.

SHIPPING.—Freights seem to have collapsed all at once. In almost all branches of shipping the depression has been sharp and severe. In some cases the reduction has been to one-half of the former rates. Ships are changing hands at prices much less than were ruling a few months ago, and there is absolutely no demand for new vessels.

SHIPBUILDING.—Messrs. Kincaid & Co., engineers, Greenock, have secured a contract for a steel twin-screw steamer of 700 tons for passenger and cargo traffic on the River Plate, South America. Messrs. Russell & Co., Glasgow, are to build the hull, and Messrs. Kincaid & Co., Greenock, the machinery and engines.

RAILWAY RATES INQUIRY.—This inquiry still proceeds in Edinburgh. Several witnesses on behalf of the traders have appeared for examination, and the proceedings, so far as Scotland is concerned, have closed much earlier than had been expected. In closing the proceedings Lord Balfour mentioned that altogether the Commission had sat for sixty days, had heard thirty-one witnesses for the railway companies, and 126 for the traders. Besides the evidence so accumulated the Commissioners had had forwarded to them fifteen hundred written statements of objections. The inquiry opens in Ireland on the 17th April.

PROFIT SHARING.—At a meeting of the employés of Messrs. Ross & Duncan, engineers, Whitefield Works, Glasgow, Mr. Duncan, who occupied the chair, mentioned that some time ago a system of profit sharing had been introduced into the works, but had been discontinued owing to the opposition of some of the men. He intimated that if the men wished the experiment tried again the firm would favourably consider such a proposal. He also mentioned that the plan of supplying the men with savings books as an encouragement to thrift had been successfully carried on.

THE LOAD LINE BILL.—An important communication from the Glasgow Shipowners' Association to Sir Michael Hicks-Beach, President of the Board of Trade, has just been sent. The communication is signed by Mr. Nathaniel Dunlop, chairman, and Mr. Muirhead, secretary of the association. It is, in effect, a protest against the second reading of the Bill, on the ground that it is not proved that overloading has sensibly, if at all, contributed to loss of life. It goes into details regarding missing ships, and points out that these aggregate only 33,216 voyage tons out of a total of 50,000,000 tons.

(From our own Correspondents.)

LIVERPOOL, 26TH MARCH, 1890.

THE BUILDING TRADE.—The carpenters, masons, bricklayers, and members of the other branches of the building trade have given notice to their respective employers of a demand for an increase in their rate of wages. Carpenters and joiners are now receiving 7½d. per hour, and demand 8½d. per hour, with a reduction in the number of working hours; the bricklayers and masons are receiving 8d. per hour, and demand 9d. The notices of the men for the above increases expire on the 1st of May, and if the advances are not granted a general strike in the building trade will most probably follow.

THE DOCK LABOURERS' STRIKE.—The labourers are still holding out, and at present there is little prospect of a settlement of the dispute between employers and men. The large shipping companies are loading and discharging their steamers with comparatively little delay, having an ample choice of picked men imported from other towns; the smaller companies are, however, put to some inconvenience. A large majority of the men would be only too glad to commence work at once, but they are blindly led on the one hand by Mr. Graham, M.P., and on the other by agitators, who make a fat living out of the strike at the expense of the unfortunate men whose wives and families are now verging on starvation. The quiet demeanour of the men in the huge processions which parade the town, headed by brass bands, and Mr. Graham in a hansom, is very marked, and betokens forced and unwilling obedience to the Union. The Liverpool Chamber of Commerce suggested negotiations based on the proposals of the Labourers' Union, but at a meeting of the employers these were unanimously refused.

CHALK FOR MARKING IRON.—A new hard chalk is being manufactured by Mr. George G. Blackwell, Fazakerly Street, Liverpool. Its degree of hardness is admirably adapted for its use in marking cast iron, and it is much superior to the ordinary forms of chalk.

THE S.S. "MAJESTIC."—This steamer has now been added to the fleet of the White Star Line, and will commence her maiden voyage on the 3rd prox. Although she is a sister ship to the "Teutonic," there are many points of difference between the two, both as regards size and engine power, and she is expected to be the faster vessel of the two.

LEEDS, 26TH MARCH, 1890.

THE IRON AND STEEL TRADES.—The output of iron and steel in this district was not lessened by the strike in the coal trade, though a scarcity of fuel was the cause of several important industrial establishments in Leeds being closed for a day or two. The announcement that the conference arranged between the coalowners and the miners' delegates had a successful termination was received in local business circles with satisfaction, for any long stoppage of the pits would have seriously paralysed the iron, steel, and engineering industries. As it was, much inconvenience was experienced, to say nothing of the feeling of uncertainty which was produced by the dispute. Furnaces have been damped down in North Lincolnshire, owing, it is reported, to the high price of fuel. Now that the coal strike has been settled business people are hoping that things will again take an active turn. Iron and steel makers are

Digitized by Google

busy in all departments, giving regular work to their hands. Still there is a scarcity of new business. The engineering trade remains brisk, and toolmakers have a fair amount of work.

THE COAL TRADE.—After a week's strike, the colliers of West Yorkshire returned to work on Monday, the masters giving an immediate advance of 5 per cent. and a further advance of 5 per cent. for the first week in August. When the second 5 per cent. is paid the miners will have received 40 per cent. advance in wages within eighteen months or two years. Prices of coal during last week were most irregular and in some cases very high, but they are now steadying. There is a good all-round demand for fuel of all kinds, slack and coke particularly being eagerly bought.

SHEFFIELD, 26TH MARCH, 1890.

THE COAL TRADE.—There is a good demand for coal of all classes, as the recent stoppage has cleared away any accumulation at the pit mouth and on the railway sidings. Prices are rather unsteady, and it is difficult to see how the present rates can be maintained unless the rate of consumption is increased. The recent strike has caused a good deal of trouble everywhere, as many thousands of workmen in rolling mills and factories have been thrown temporarily out of employment.

WAGES IN THE ENGINEERING TRADES.—The turners and fitters, both society and non-society men, have issued a circular to their employers asking for an advance in wages of 2s. per week. Considering the prosperous state of the trade, and the fact that no advance has been given during the past seventeen years, it may be interesting to give the replies of some of the employers. Mr. E. Tozer, of the Phœnix Bessemer Works, Rotherham, is surprised at the request, as no reduction of wages has taken place during the depression in trade. Hadfield's Steel Foundry Company, Limited, said they would give the advance, and Messrs. S. Osborn & Co., Clyde Steel Works, also. Mr. Ambrose, of Shardlow, had already given it to those who were worthy of it. Messrs. John Brown & Co. and Messrs. Cammells have not had time to consider the matter.

NORTH STAFFORDSHIRE, 26TH MARCH, 1890.

THE COAL AND IRON TRADES.—Though an advance of 5 per cent. in colliers' wages has been conceded, accompanied by a promise for a further 5 per cent. on August 1st, there is a feeling amongst local coal and iron masters that the men have taken an unfair advantage of the state of trade to unduly press their claims. Most firms in this district consume a large proportion of the fuel they raise in their own ironworks, and consequently are unable, with a falling iron market, to recoup the additional cost of production. There appears to be little short of a collapse in prices of crude and finished iron. Between this date and the quarterly meetings, when contracts are largely negotiated, it is to be seen whether buyers or sellers are to arrange current prices.

THE POTTERY TRADE.—Efforts are being made to extend the arrangement by which an advance in prices has been declared in the home markets to the trade with the United States. It does not often occur that an artificial enhancement of values can be of long duration, and the present movement is not likely to be an exception to this rule.

DERBY, 26TH MARCH, 1890.

THE COAL CRISIS.—The coal trade of the district has once more settled down into a normal groove. Not much inconvenience was caused locally by the crisis just passed, as it had been anticipated that whatever the result of the struggle prices were sure to rise after any settlement, and hence it was wisdom to stock, a conviction that was acted upon wherever posssible. House coal realised fancy prices in some few instances, but the highest figure that we can hear of for engine slack was 13s. delivered in Derby, a quotation that only held good for two or three days, and which was at once reduced to 10s. when the settlement was effected.

THE MIDLAND RAILWAY.—The Midland Railway Company has entered into an agreement to support in Parliament the proposed amalgamation of the North British and Glasgow and South-Western Railways, conditionally, amongst other things, on their agreeing to forward annually by the Midland route a stated proportion of English traffic under their control. The Midland Company have extended their engine sheds at Derby, and great activity also prevails in the carriage department. Many regular travellers by the Midland line are greatly inconvenienced by the recent changes in the passenger service, and a well-attended meeting was held at St. Albans to protest against the alterations, when it was decided to memorialise the company.

THE DERBY GAS COMPANY.—The continued expansion of Derby, which has grown from a place with 17,400 inhabitants in 1820, when the gas company was originally incorporated, to its present dimensions, with close upon 100,000 people, obliges the company to contemplate extensions, and it seeks for powers to raise £160,000 for the purpose. The Town Council oppose the scheme, as they themselves are seeking to pass a bill through Parliament that shall enable them to purchase the undertaking under compulsory clauses. The Corporation already possess the waterworks, which are conducted in an admirable manner.

AN IMPROVED WASHER.—Messrs. Peters, Bartsch, & Co., of Derby, have just brought out an improved form of washer, which is particularly applicable where high pressures of steam or very great heats are used. It consists of a ring made out of soft metal sheeting, and contains a groove all round it on the outside. This groove is filled with some packing material, such as asbestos, which is capable of resisting great heat.

CARDIFF, 26TH MARCH, 1890.

COAL AND COKE.—The most noticeable feature in the steam coal trade is the abnormally high price which small coal is, and has been for the past few weeks, realising. The current price is from 10s. to 10s. 6d. f.o.b., which, beyond the railway carriage from the pit's mouth, can be taken as absolute profit, as the cost of winning small coal is practically *nil*. It is feared that this rosy condition of things cannot, however, last long, and sellers show great eagerness to accept forward contracts at much less than the above-named figures. Large coal finds a steady sale, best steam being quoted at 16s. to 17s.; second, 15s. 6d. to 16s.; and inferior descriptions from 14s. 6d. The house coal market is steadier than is generally the case in spring, which is no doubt caused by the fact that a certain quantity of bituminous coal is being mixed with steam coal on account of the scarcity of the latter. For coke there is a moderately active demand. Several export orders have come to hand, which more than make up for the slight falling off in the inland business.

IRON AND STEEL.—The pig iron market is on a more satisfactory basis, and some legitimate transactions are reported at better figures. Now that the rash speculation in the warrant market has collapsed there is a prospect of the market creeping slowly up to a profitable basis. Inquiries for steel rails are more numerous, and a few good orders have been placed. Steel bars are irregular, makers quoting £7 10s., but orders are being accepted at less.

IRON ORE.—Deliveries of Spanish ore have been heavy, and as ironmasters are fairly well bought by contract, there is naturally very little outside business doing. Prices in Spain are very firm, owing to the heavy demand from Germany and America. Rubio is quoted at 16s. 6d. c.i.f. Cardiff and Newport, 17s. Swansea, 17s. 9d. Middlesbrough, 17s. 9d. West Hartlepool, 17s. 6d. Tyne, 17s.. 6d Ayr, 17s. 9d. Glasgow.

BARROW-IN-FURNESS, 26TH MARCH, 1890.

HEMATITE IRON.—There are indications that the attitude of makers of hematite iron in restricting the output, and in refusing to run any of their make into warrant stocks, will bring about an improved tone and an increased trade. The demand is fuller, and warrants have gone up to 65s. per ton. Makers, however, are still quoting 70s. to 72s. 6d. for parcels of mixed Bessemer Nos. net f.o.b. The most gratifying evidence of the improvement in trade is furnished by the rapidity with which stocks are being reduced. During the week 4,764 tons of hematite have been cleared from the warrant stocks, which now remain at 367,916 tons, or 13,731 tons less than in the beginning of the year.

STEEL.—No life is shown in any of the departments of the steel trade. Makers are busy, but it is evident they will soon be in want of new orders to supplement the contracts which represent deliveries far ahead. It is also certain from the present tone of affairs that makers will have to accept lower prices. Business is reported at £5 15s. for heavy sections of rails, but local makers are quoting £6 5s. per ton. There is practically nothing doing in the tinplate trade. Steel shipbuilding material is in large delivery, and orders are well held, though no new orders are coming to hand.

MIDDLESBROUGH, 26TH MARCH, 1890.

PIG IRON.—At the market held yesterday there was a good deal of animation. The price of No. 3 began stiff at 53s. per ton for G.M.B. for delivery this month, but this soon gave place to 52s. 10½d. Before the close, however, it had recovered to the opening price. The prospect is favourable, and makers will not abate their price, but will stand out for 60s. They have a large stock accumulating on their hands in consequence. Merchants prefer warrants and are taking largely from the public stores. Upwards of 1,600 tons have been drawn from Connal's stores in the course of the month. Cleveland warrants are quoted at 53s. cash, with a tendency to rise. The stock in Connal's store on Monday amounted to 161,060 tons, as against 166,752 tons a week back, being a decrease over the week of 5,692 tons. In hematite iron, East Coast brands are quoted at 75s. per ton f.o.t., makers' iron, mixed numbers.

MANUFACTURED IRON AND STEEL.—Iron is active and steel rather quiet. Iron ship plates are at £6 17s. 6d.; ship angles, £6 15s.; common bars, £7, all less the usual discount; steel ship plates, £7 15s.; angles, £7 15s.; rails, £6 per ton.

ARBITRATION BOARD RETURNS.—Mr. Waterhouse's returns show decreased sales of finished iron at increased prices. The average net selling price per ton, for the two months ending the 28th ult., is certified to have been £6 12s. 2½d., against £6 1s. 4d. during the preceding two months. This increase in the selling price carries with it an advance in wages of 6d. per ton on puddling, and 5 per cent. on all other forge and mill wages, to take effect from the 31st inst.

SUNDERLAND, 26TH MARCH, 1890.

SHIPBUILDING AND ENGINEERING.—Fortunately the strike in the engineering trade is at an end. Orders are still scarce and inquiries few; only one steamer has been contracted for during last month—viz., by Messrs Short Brothers, Pallion, for the Prince Line, Newcastle. This vessel is to be fitted with three-crank quadruple-expansion engines, by Messrs. George Clark, Limited. The high-pressure cylinders will be placed tandem fashion. The boiler working pressure is to be 200lb. per square inch, and the furnaces will be Purves' ribbed flues, manufactured by Messrs. John Brown & Co., Limited, Sheffield.

SHIPPING.—There has been a decided improvement in the Black Sea market, owing partially to the opening of the Sea of Azof. If shipowners should hold aloof a return to remunerative rates is probable. Outward business to the Mediterranean continues fairly good, but in the East the market is dull and freights are declining. There is no improvement in the Baltic trade, the open winter having left on hand large stocks of coal. There are some signs of improvement in American rates. With the high price of bunker coals and increase in other items of expenditure, without further general improvement in freights it cannot be said that the shipping trade will prove successful this year. Local coal shipments are very fluctuating. During the last week 68,540 tons were shipped, as against 84,257 tons, 65,231 tons, 78,647 tons, 56,962 tons, and 75,402 tons in the immediately preceding weeks.

THE RIVER WEAR COMMISSION.—The monthly returns show a falling off in revenue of £461 2s. 5d., as compared with February, 1889. This is largely due to the decrease in coal shipments. The Commissioners are arranging for a somewhat smaller expenditure on revenue account during the current year.

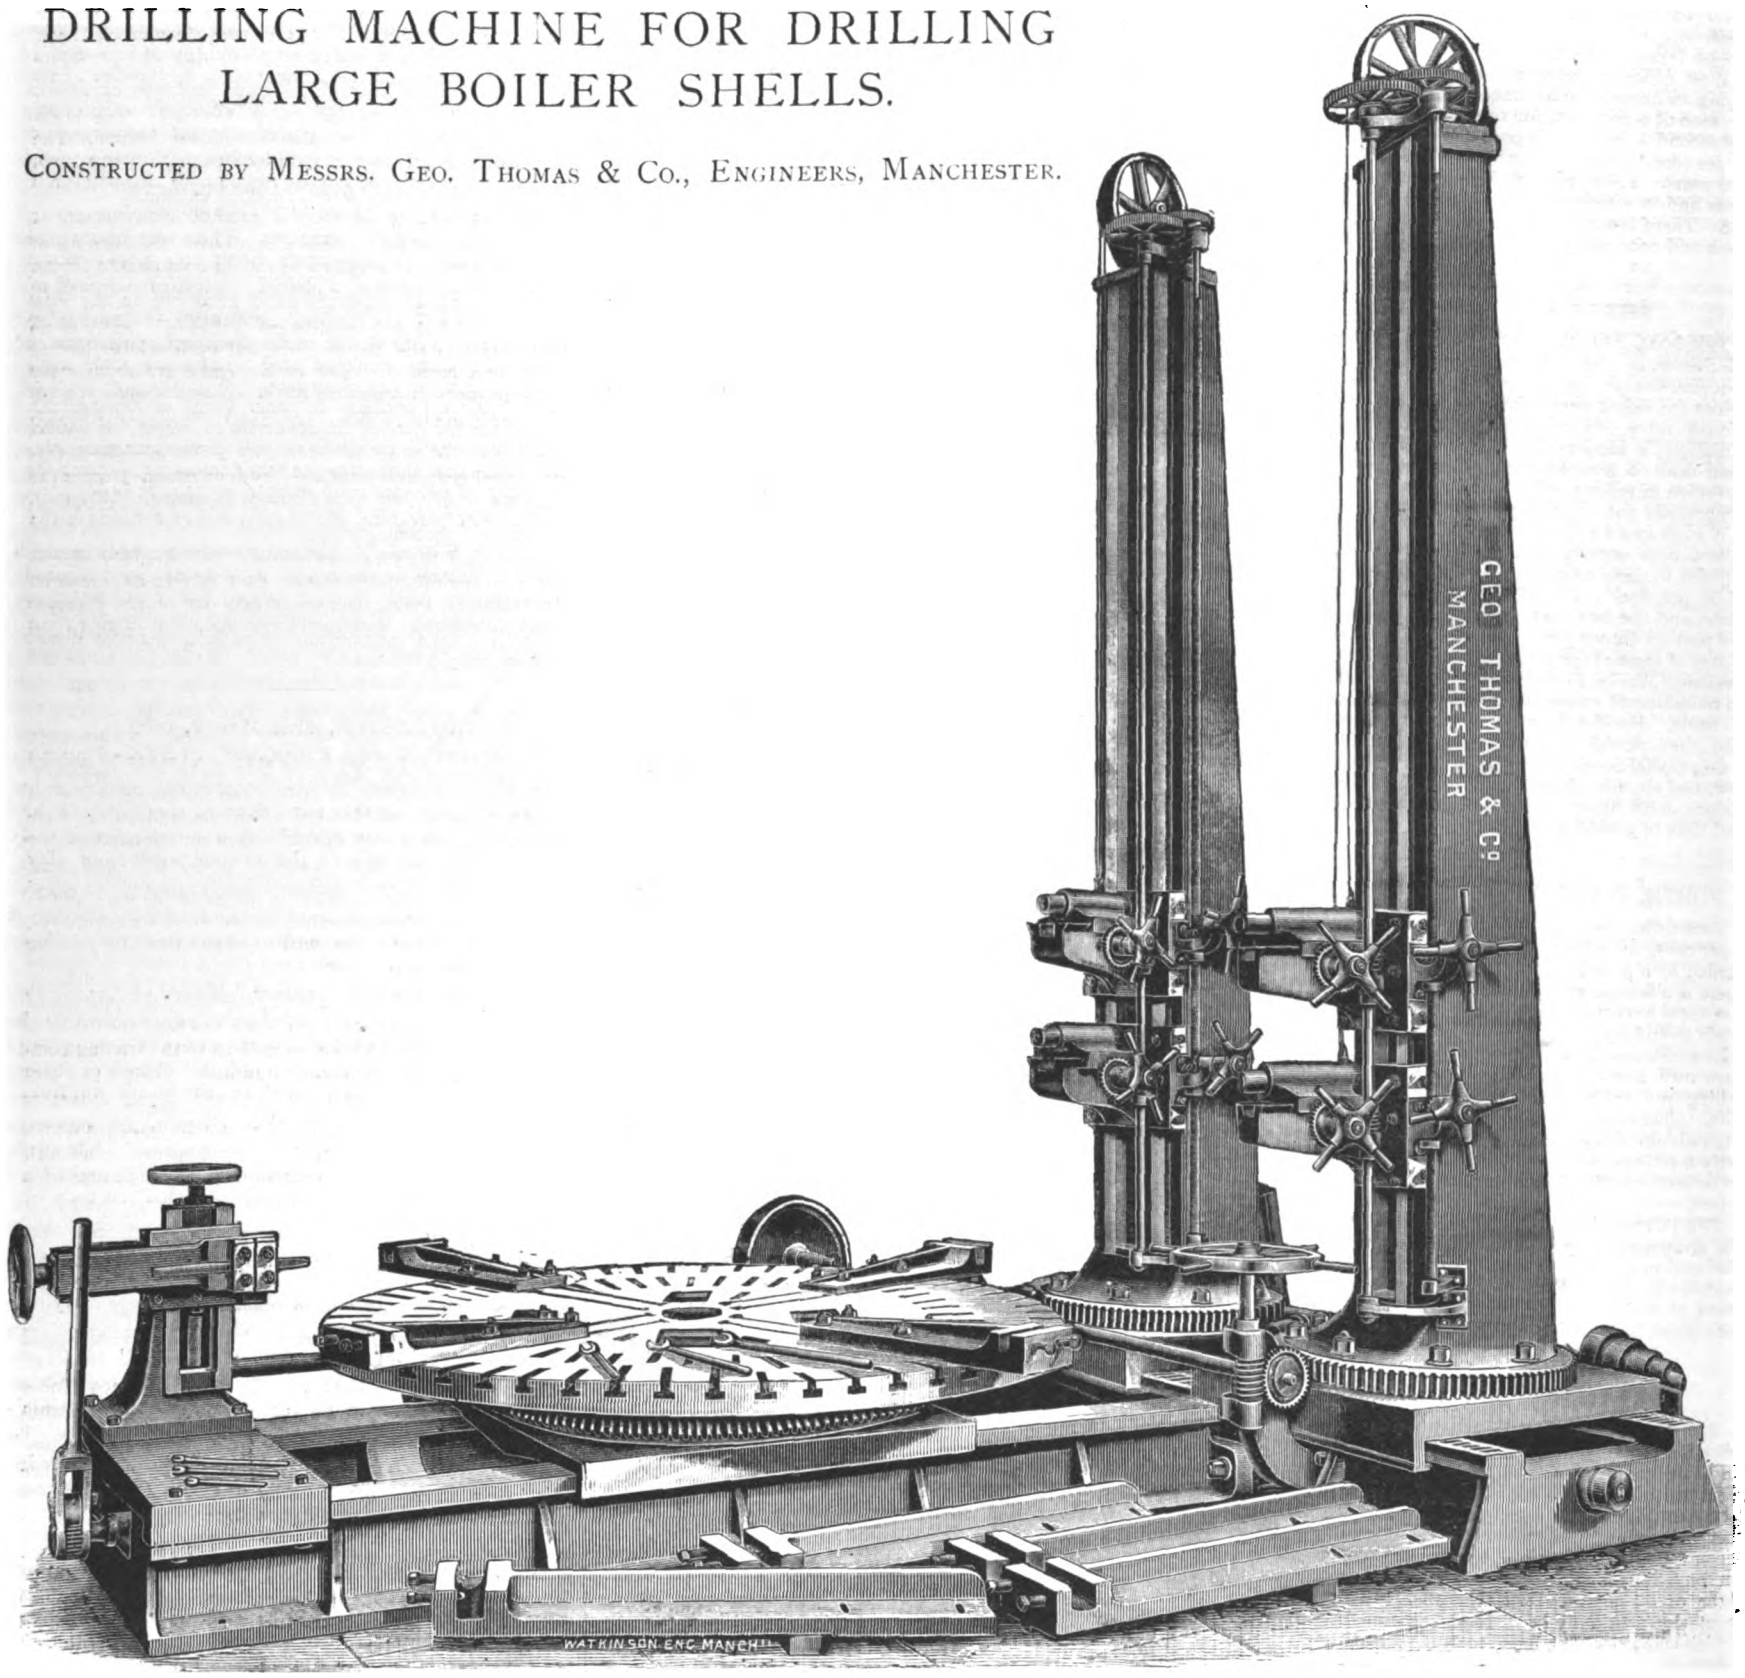
NEWCASTLE, 26TH MARCH, 1890.

SETTLEMENT OF THE ENGINEERS' STRIKE.—Through the mediation of the Mayor of Newcastle, the representatives of the workmen on strike and the employers were brought together on Monday afternoon, and after some discussion, a settlement was arrived at on the basis of the concession to the men of the 53-hour week from May 10th, the men on their part undertaking to confine themselves to a limited number of holidays per year, and to keep their machines running up to noon on Saturdays, which, after the date named, is to be the time for ceasing work. The men's representatives also promised to support a proposal for the establishment of a Board of Conciliation, by which disputes might in future be settled. The strike, though it has lasted only eight days, has been the cause of serious loss to all concerned, as well as to the trading community generally, involving, as it did, the idleness of some 50,000 men for the time indicated, and the withdrawal from circulation of the wages they would have earned.

SHIPBUILDING.—The Scotswood shipbuilding yard, which has lain idle several years, is about to be opened by a South American company, who contemplate the building of a fleet of river steamers, of which they will be the owners. It is understood that the company will also engage in the building of steel and iron bridges for South America, but this part of the undertaking will not be entered upon for some time yet. The Palmer's Shipbuilding and Iron Company launched, on Saturday, a vessel of 6,600 tons carrying capacity, for the British Shipowners' Company. The engines, which are triple expansion and of great power, are being supplied by the builders.

ORDNANCE WORKS.—At the Elswick Ordnance Works some heavy orders for different types of guns and gun carriages have recently been booked, and briskness in all the departments is now assured for the remainder of the year. The foundations for the new ordnance works at Jarrow are now being marked out, and building operations will be commenced in the course of a few days.

THE COAL TRADE.—The ascertainment of coal prices realised in the months of December, January, and February having been of a nature to admit of a wages advance being given to the miners, the coal owners, at a conference held on Saturday, announced to the representatives of the latter that they would give an advance of 7½ per cent., to take effect from the 31st inst. This was accepted by the representatives. Owing to the engineers' strike stocks of manufacturing coals have somewhat increased, but a resumption of work having now taken place it may be expected that the surplus will speedily be cleared off.



DUNDEE, 26TH MARCH, 1890.

FLAX AND JUTE TRADES.—Both branches of the trade of this district continue quiet. Flax, tow, and codilla are quiet in all positions. Prices on spot are low, and on contract only a limited business is passing at late rates. A fairly good business is passing in flax yarns, and, while prices have ruled low, spinners are becoming less inclined to entertain offers except at some advance. Makers of linens are pretty well employed, and there is a good all-round demand. Narrow goods are still most in request. The spot demand for jute is fair, but in shipments there are few transactions reported, and quotations are lower. In the Calcutta market both loose and baled jute are slow of sale at late rates. In New York Dundee burlaps have been quoted during the fortnight at 5¼c. for 40 in 10½oz. The demand in this market is rather slacker, although light goods show an improvement, and some makers are well booked forward.

DRILLING MACHINE FOR DRILLING LARGE BOILER SHELLS.

CONSTRUCTED BY MESSRS. GEO. THOMAS & CO., ENGINEERS, MANCHESTER.

POLYTECHNIC INSTITUTE FOR SOUTH-WEST LONDON.

THE Bishop of London recently called a meeting at Fulham Palace with the view of promoting a Polytechnic Institute for South-West London. The Bishop explained the objects of the Institute, and said it was proposed to provide commercial and technical education for those who would have to obtain their living, although he disclaimed all intention of teaching trades, which he said should be done in the workshop. Earl Cadogan had presented the promoters of the movement with a suitable freehold site, together with a sum of £1,000, and the Charity Commissioners had promised £50,000 provided a like sum were raised by subscription. Of this £32,000 had been promised, and a committee was appointed for the purpose of raising the remainder, so that the scheme is likely soon to be carried out. Similar movements are being carried out in other districts of London with the same prospects of success.

DRILLING MACHINE FOR DRILLING LARGE BOILER SHELLS.

THE machine illustrated above is intended for drilling and end-turning marine boiler shells from 4ft. up to 14ft. diameter and 12ft. high. from the top of the table, for turning the flanges of boiler fronts up to 9ft. in diameter, and for drilling, tapping, and inserting studs up to 1¼in. diameter in boiler backs. A strong circular table 8ft. in diameter is fitted with four jaw-brackets, which overhang the table and admit the larger sizes of boilers. The table is arranged to slide along the longitudinal bed by means of a hand-screw and ratchet lever. The transverse bed carries the drill standards and a pinching rack for screwing them. Four drills can be worked simultaneously either on circular or horizontal seams. The machine has two standards, each fitted with two saddles. The steel spindles are 2½in. in diameter, and their noses work against hardened steel washers, lock-nuts being arranged at the other end for purposes of adjustment. There is a self-acting feed motion with a traverse of 6in., and a hand-wheel is provided for the quick withdrawal of the drill. A lever is placed at the bottom of each standard for stopping, starting, or reversing the spindles. The standards are made to swivel to any angle by a worm and worm-wheel. The table is rotated either by hand or power: by hand when drilling, and by power when turning boiler-end fronts. The vertical tool standard for turning the ends has vertical and horizontal adjustments, so that any size of boiler fronts can be turned complete. Messrs. Geo. Thomas & Co., engineers, Manchester, are the makers.

Advertisements intended for insertion in the current week's issue should reach our London Offices not later than first mail delivery on Thursday morning. Scale of charges for displayed advertisements on cover and inside pages will be forwarded on application. Orders for single advertisements must be accompanied by payment in order to insure insertion, the charge for which is 2s. 6d. for the first four lines or under, and 8d. for each additional line. Situation advertisements (Vacant or Wanted) 1s. for two lines or under, and 6d. for each additional line—which averages eight words. While all practical regularity in the insertion of serial advertisements will be observed, it can only be absolutely guaranteed in the case of those ordered to appear weekly.

As we go to press early with certain of our advertisement pages, all Alterations to Standing Advertisements should reach the Publisher not later than 2 o'clock on Wednesday afternoon in each week.

All accounts are payable to GEO. CAWLEY, 358, *Strand, London, W.C. Cheques should be crossed Manchester and Liverpool District Banking Co., Limited, 75, Cornhill, London, E.C. Post Office Orders should be made payable at the Post Office, 369, Strand, London, W.C.*

Industries:

FRIDAY, 28TH MARCH, 1890.

THE ENGINES AND ENGINEERS OF THE NAVY.

AT a public dinner a short time since we heard a distinguished marine engineer say that, if the manager of any private concern made so many mistakes, and allowed so much inferior work to pass, as take place in the Engineering Department of the Navy, he would be instantly sent about his business. Intimately connected with this is the training and professional standing of the engineer officers, and, as both of those subjects are at present being discussed, we propose to refer to them at some length. During the manœuvres of the past two years, and also in the speed trials which are made in the ships of the Navy, we certainly hear of a greater proportion of breakdowns than occur in the merchant service. No doubt part of this is due to the special circumstances under which engines in the Navy are worked, and especially to the great variations of speed and sudden reversings to which they are subject; but these should be obviated by more careful design and greater strength, both of which could be arranged by competent engineers. Then, again, in the matter of speed, which in the present day is the most important quality a ship of the Navy can possess, comparisons between the performances of ships of the merchant service and of the Navy are not at all favourable to the latter. The First Lord of the Admiralty, in his recent statement issued along with the Naval Estimates, touched on all these subjects. He gave a list of ships in which, with certain few exceptions, the machinery trials had passed off satisfactorily on the first occasion, and stated that in most cases the indicated horse-power had exceeded the amount named in the contract, and that this was produced with less air-pressure than that specified. He gave a further list of vessels in which the full-power trials had been postponed for various reasons, which, however, we are afraid were somewhat of the official type. We need not go into this just at present, but it cannot be denied that the impression among marine engineers is that the number of partial failures in the machinery of the Navy is much larger than it ought to be. The First Lord admits that various defects have been observed, but in many cases they have been made good by the engine-room staff; and he expresses the hope that, with greater experience in the working of the machinery, the results will steadily improve. He points out that the design of the engines and boilers of a ship in the Navy is more difficult than that of one in the merchant service, and that it must depend largely upon the service for which she is built. The engines and boilers of a man-of-war are not required to work generally at their highest power, as rapid moving from place to place is not the ordinary work of a war vessel. Moreover, in a fighting ship the weight of the machinery and the space it occupies are primary considerations, it being considered necessary to protect the engines and boilers, either by keeping them below the water-line, or, if above, by defensive armour. The engines must therefore be so designed as to be capable of performing the varying services required of them, which comprise working generally at moderate powers, an ability to meet frequent changes of power according to the duty in which the ship may be engaged, together with a reserve power which may be exerted when required. These conditions, combined with the limitations of weight and space, tend to make the engines less economical in consumption of fuel; and the frequent changes of power tell much more severely on the boilers than would be the case if the engines were working at a nearly uniform power, as in a merchant steamer. In order to meet the complaint of want of speed, the sizes of the boilers have been increased in the ships now building by from 16 to 25 per cent.; that is to say, instead of continuing to design the boilers so that the steam required for full forced draught power can only be obtained by the exertions of the very best stokers and picked coal, on measured mile conditions, the present policy is to increase the weights and the dimensions of the boilers, so that the higher powers occasionally required may be more readily developed and maintained. The new cruisers are expected to have a speed of 20 knots an hour on their trials, and it is to be hoped that they will come very near to that in their everyday work.

We must give the present Board of Admiralty credit for pursuing an intelligent policy, both in the administration of the dockyards and in the design and construction of ships and engines. The next thing to which they ought to direct their attention should be the training of the officers and men who design and take charge of the engines. This subject is now being discussed, and it is somewhat amusing to note the varied opinions which are being expressed regarding it. One of the most remarkable was given by Rear-Admiral R. C. Mayne, C.B., M.P., in a lecture recently delivered at the Royal United Service Institution, and at which the First Sea Lord of the Admiralty presided. He discussed the whole field of Naval policy and organisation, but in this article we will only notice what he said about engineer officers, of whom he makes very short work—in fact, he would make them as a class disappear. He thinks that there is no reason whatever to doubt that if an executive officer devotes as much time, and no more, to learn engineer's work, as he does to learning torpedo work, he would not only be perfectly competent to supervise the engine room artificers, by whom the principal part of the engineer work is now performed, but the "engine-room lieutenant" would bring to the discharge of his supervising duties the habits, constitutional and acquired, of supervision and command, which are known to be characteristic of the class which he joined on first entering the service. The engine-room staff would thus comprise a military officer with one or two assistants, and below them there would be engine-room artificers who would attend to the practical part of the work. We can only characterise this proposal as one of the strangest ever made by any man of such professional standing as Admiral Mayne. A modern warship is the embodiment of all the latest inventions of every department of mechanical and electrical engineering, and it is calmly suggested to hand this over to the charge of a naval officer with a training in engineering extending over a few months, assisted by engine-room artificers. If this were carried out, not only would it be most disastrous to the naval service, but it would also most effectually prevent the training of

Digitized by Google

men who were capable of designing or superintending the construction of the engines of ships of war. The engine-room artificers could never develop into such men, for as a rule their education would be deficient, and the designs suggested by the "engine-room lieutenant" would be mere copies, and generally bad copies, of existing types, and thus, not only would there be stagnation, but deterioration in the engines of the Navy.

We are strongly of opinion that, in the training of engineer officers of the Navy, every opportunity should be given for the development of individual ingenuity and skill, and that advantage should be taken of local institutions and engineering establishments for attracting a few of the best of their young men of each year into the Navy. Liverpool, Newcastle, and Glasgow are not only centres of engineering and shipbuilding industry, but they have also educational institutions which are quite as good as any in London for the training of engineers. We have always advocated the utilisation of local advantages, and deprecated any centralised system of education for any department, or the attempt to force all through the same groove, and expressed the opinion that the better course would be to hold out inducements to localities, which would be sufficient to bring out all the men who were wanted for the engineering department of the Navy, and who would have the benefit of the best practical experience in the locality, together with as much theoretical knowledge as they were likely to utilise. We are very much pleased to observe that such a plan has been adopted by the Admiralty, and that notices have been issued stating that an examination of candidates for appointment as probationer assistant engineers in Her Majesty's Navy will be held at the Royal Naval College, Greenwich, commencing on the 29th of May. The ages of the candidates are to be from 20 to 23, and they must have undergone instruction in a College for Technical Education, and three years' training in an approved engineering establishment. Applications must be made before the 1st of May to the Secretary of the Admiralty, Whitehall, London, S.W. This is one of the wisest steps ever taken by the Admiralty, for we are sure that the men who have served their apprenticeships in good workshops, and also undergone a regular course of instruction in the College in their locality, will be well qualified to enter the Navy as junior engineer officers, and they will not be too old to learn those habits of supervision and command which Admiral Mayne thinks so necessary. Opportunities might be afforded to some of them, after they had been in the service for some time, for attending higher courses of instruction, but as a rule this would be unnecessary, as their early education would enable them to keep up with the developments in their profession. We by no means believe that college class-rooms are always the best educational establishments. Much sounder and more useful instruction may be obtained in the engine room and the workshop supplemented by private study. We are much pleased that the policy of the Admiralty is towards the encouragement of individuality and the utilisation of local advantages and institutions, and we trust it will be persevered in. We also hope that, if Admiral Mayne's proposals ever appear in an official form, or even under official patronage, they will receive the most determined opposition.

INDUSTRIAL LEGISLATION IN 1890.

The number of Bills that have been introduced into Parliament this session, with a view to influencing industrial affairs, is more than ordinarily large, and if the session should afford adequate opportunities for their consideration, it seems probable that the statute book, at its close, will not be without additional provisions that will be increasingly onerous to the mine owner and manufacturer. There are other Bills that are drafted with a view to regulating and controlling the conditions under which limited companies are now promoted and established, but of such proposals it need only be said that, while they may make it increasingly difficult to establish on a limited liability basis, or, rather, to transfer to public from private ownership, businesses that are notoriously lean and substanceless, they are likely to aid in the maintenance of sound and prosperous concerns. Perhaps the Bill around which the greatest fight is likely to range is that which proposes to restrict the hours of labour in mines to eight per day. This Bill is backed by the miners' representatives, Mr. Pickard and Mr. Wm. Abraham, by Mr. Conybeare, Mr. Jacoby, Earl Compton, and others; but the names of Mr. Thomas Burt, the tried friend of the miners; of Mr. Crawford, of Durham, who has been for twenty years or more the secretary of the largest miners' union in the world; and of Mr. Bradlaugh, who has long been known as a good friend to this class, and one of their chosen favourites, are conspicuous by their absence. The Bill is a short one, having only three clauses. The first of these is the defining, the second the enacting, and the third the penalising clause. The enacting clause simply provides that no one shall be employed underground in any mine for a period exceeding eight hours in any twenty-four hours, "from the time of his leaving the surface of the ground to the time of his ascent thereto, except in case of accident," under a penalty of 40s., which penalty is to be recovered in the same manner as under the Acts relating to factories and workshops. Another kindred Bill is backed by Mr. Fenwick, another miners' representative, and requires the wages of every workman engaged by time to be paid in full at least once in each week. When engaged otherwise than by time the workman's wages are to be paid in full at the expiration of not more than fourteen days from the commencement of the employment, or from the last pay-day. The last-named Bill is one that is not likely to be attended with much, if any, disadvantage to employers generally, although it may entail some inconvenience to those who have hitherto been in the habit of paying more or less in kind, or of retaining a certain part of each week's wages in hand.

From mines to quarries is an easy and not unnatural transition, and among the Private Bills that reappear on the legislative programme of the current session is the one that was introduced last year for the regulation of quarries. This Bill, which is backed by Mr. Broadhurst, Mr. Ellis, Mr. Abraham, Mr. Childers, and others, limits the age at which children shall be employed in quarries to ten, restricts the hours of boys, girls, and women to 54 per week and ten per day, allows half-hourly intervals for meals during each five hours, and an hour and a half during each eight hours, and requires the owners to furnish periodical returns of their production, the number of persons employed, &c. In cases of accident owners are required to make returns to the inspector of the district within twenty-four hours, and where loss of life or serious personal injury has occurred from an accident, the place is to be left as it was immediately after the accident until visited by an inspector. In cases of quarries being abandoned or discontinued for the time being, they are to be made secure against accident by fencing, but where this discontinuance occurred previous to the passing of the proposed Act, the fencing shall only be required where the quarry is within fifty yards of a road or footpath. The 8th section of the Bill proposes to provide for the appointment of inspectors, who, under the 10th section, have power to examine quarries at all reasonable times by day and night, and who, under the 11th section, are authorised to require anything that may be dangerous or defective about the quarry to be remedied by the owner. Inspectors are required to make an annual report to Parliament as the inspectors of mines are now accustomed to do. Among the proposed general rules, it is required that the practical manager of every quarry shall have had at least five years' previous experience of its working, and regulations are laid down in reference to the use of gunpowder and other explosives. Other provisions deal with the employment of ladders, with the attendance of enginemen, the use of brakes and indicators, the fencing of exposed and dangerous parts of machinery, and the adoption of safety valves and gauges for boilers, &c. Offences against the Act are to be punished by fines not exceeding £5. A quarry, for the purposes of the Act, is to be a "place in which persons work in getting slate, stone, coprolites, or other minerals, clay and brick earth excepted, and all slate quarries now worked under the Metalliferous Mines Act, and every excavation that is being made for commencing or opening any quarry." This definition would extend the Act to the working of the ironstone measures of Lincolnshire, Northamptonshire, and other parts, and to the quarries that provide Cleveland and other districts with the limestone used for a flux in the blast furnace, so that the Bill is likely to have some, although probably not a very serious, effect on the iron trade.

That old familiar face—a Bill to Amend the Law Relating to the Rating of Machinery—reappears in the present, as it has done in several former sessions. It is backed this year by Sir B. Samuelson, Mr. Tomlinson, Sir W. Houldsworth, Sir F. Mappin, and others. The Bill is almost identical with that of former years, and it provides that in estimating the rateable value of any property no machinery, whether attached to the premises or not, shall be taken into consideration, except certain fixed motive powers and the fixed appurtenances thereof, and the "shafts, wheels, drums, and other fixed power machinery, which transmits the action of motive power to other machinery fixed or loose." This Bill is founded upon the report of the Select Committee appointed two years ago to deal with this vexed question, and it is an eminently reasonable one in reference to its main provisions. It is to be hoped that it may become law during the present session, and thereby get rid, once and for all, of the serious discrepancies and anomalies that are every day occurring in the rating of machinery. Another Bill introduced this session, and described as a Bill to divide rates between landlord and tenant, will, of course, affect manufacturers only in so far as it may affect other tenants, and does not, therefore, call for special mention. So also with the Bill to provide for the placing of a mark of origin upon foreign goods, which is backed by Mr. Howard Vincent and nine other members, and which provides that all goods of foreign manufacture "which do not bear in a legible and conspicuous form a definite indication of the country" in which they were made or produced shall not be imported into the United Kingdom, as if they were specified in section 42 of the Customs Consolidation Act of 1876. This Bill is, of course, intended as a supplement to the Act of 1887. Another Bill, which is intended to secure the more effectual prevention of fraudulent trading, and which is backed by Mr. Arthur O'Connor, Sir A. Rollit, and others, proposes to enact that in cases where a business is being carried on by others than the so-called proprietors, the full name, residence, and other occupation, if any, of every person having any proprietary interest in the business, shall be registered. A false statement under the Act shall be treated as a misdemeanour, and shall be punishable by twelve months' hard labour. Access is to be given to the proposed register on payment of an inspection fee of 1s.

Among the other Bills that are printed and awaiting the consideration of Parliament at this comparatively early stage of the session are the Tribunals of Commerce Bill, which is fathered by Mr. Jacoby, Mr. Montagu, and others, the object of which is to establish tribunals for determining speedily and economically claims and disputes arising out of trading transactions, through the machinery already provided by the County Courts; the Partnership Bill, introduced into the House of Lords by the Lord Chancellor, which defines the relations of partners to persons dealing with them and to one another, and which provides for the duties and rights of partners on dissolution; the Companies (Winding-up) Bill, which is a Government proposal, backed by the President of the Board of Trade, and which is intended to extend the policy of the Companies Act of 1867, by giving jurisdiction in the winding-up of companies to county and other local courts, and to assimilate the law and procedure in the winding-up of insolvent companies to the law and procedure in the bankruptcy of individual debtors; a Bill, backed by Mr. Warmington and others, to amend the law relating to the liability of directors and others for statements in prospectuses and other documents soliciting applications for shares or debentures, the effect of which is to make directors personally liable for such statements; and finally, a Bill proposing to enact that incorporated companies shall be entitled to act as executors, administrators, and trustees, and in other fiduciary capacities.

OFFICIAL REPORT ON THE MAURICEWOOD DISASTER.

The Report of Messrs. Johnson and Bell to the Secretary of State, on the disaster which occurred last year at the Mauricewood Colliery, near Edinburgh, belonging to the Shotts Iron Company, has just been issued, and if the opinion therein expressed be correct the disaster must be added to the long list of mining casualties the causes of which are involved in mystery. The Commissioners give a considerable amount of information on various points which were obscure, but they state that the cause of the fire remains, and indeed must remain, unexplained. No evidence was given to show that it arose from a malicious act, and there is nothing indicating that it was caused by spontaneous combustion. The Commissioners say, therefore, that they must attribute the fire to some accidental cause, for which, however, no blame can be attached to the mine owners. But, although they cannot explain the cause of the disaster, the Commissioners show how its consequences were brought about, and from their remarks no doubt some useful lessons will be extracted. These they attribute mainly to the fact of one branch of the upcast air shaft being led through the engine room at the 80 fathom level,

Digitized by Google

and this they consider a faulty arrangement. It is impossible that the engine room—and this engine room is one in which the pumps were proved to be working for eighteen hours out of the twenty-four—could be sufficiently ventilated to make it habitable to the enginemen, by means of returned or upcast air, heated in its passage by contact with steam pipes. Consequently it is not surprising that the engineman got into the habit of keeping the door a little open for the purpose of obtaining air from the downcast direct to the engine-room to give a supply of fresh air. The consequence was to make a direct communication between the upcast and the downcast airways, which became, in the opinion of the Commissioners, the principal source whence the smoke got into the main incline, and was carried down and so filled the lower workings of the mine; and immediately on the fire breaking out the air in the upcast shaft must have been expanded by the heat, volumes of smoke must have been generated by the combustion of dry timber and mineral dust, and the total volume of air and vapour to be carried to the surface must have been so increased thereby that it would greedily seek every avenue of escape on the road. Such a communication between the upcast and the downcast airways as was afforded by the engine-room at the 80-fathom level was, of course, instantly brought into action. As such arrangements are not uncommon in other pits, no doubt the attention of the mining inspectors and the mine owners will be directed to them, and a remedy provided. The door was, it is admitted, not very substantial in its construction, and, although it comes in for a mild censure, the Commissioners are not disposed to attach any responsibility to the owners on its account. On the question of the double shaft, to which, and to the operations connected therewith, the miners' representatives directed the attention of the Commissioners, they think that the Shotts Iron Company complied with all the requirements of the statute, and acted in the best interests of the workmen. The Commissioners seem to have considered the evidence very carefully from every point of view, and their decisions appear to be well founded. We doubt, however, whether they will satisfy the representatives of the miners.

THE LATE J. G. HALSKE.

We regret to record the death, which occurred at Berlin, of Mr. Johann Georg Halske, the co-founder and, for many years, partner of the well-known firm of Messrs. Siemens and Halske. He was born at Hamburg on July 30th, 1814, and in early life went to Berlin, where he set up an engineer's shop in 1844. Soon after he made the acquaintance of Dr. Werner Siemens, and it was in Halske's workshop that Werner Siemens, assisted by the mechanical skill of the former, was able to work out his first inventions in telegraphy, so as to bring them before the public. In 1847 the two entered into partnership and laid the foundation to the telegraph construction works which at the present day give employment to thousands of workmen both at Berlin and Charlottenburg and at several branch establishments. Mr. Halske left the firm in 1867, and since then has been an active member of the municipality of Berlin.

Letters to the Editor.

THE BRITISH COMMITTEE AT THE LATE PARIS EXHIBITION.

To the Editor of "Industries."

Sir,—As there is no wrong without a remedy, there must be some remedy for being slandered by *Truth*, but it is hard to find. May I try to discover one by appealing to the fairness of the press in general to correct some misstatements of which one of their number has been guilty, but which he declines to withdraw?

It was stated in a paragraph in *Truth* that exhibitors at the late Paris Exhibition were being dinned for a testimonial to the British Commission, and various comments were made thereon.

May I ask you to state—(1) That no testimonial has ever been proposed to the British Commission, Committee, or Council; (2) that I myself some months since declined to accept any testimonial when on two several occasions the flattering suggestion was made; (3) that some of the exhibitors, acting entirely on their own initiative, are subscribing to make a gift to the members of the staff, who did the work and got none of the credit for it.

The question is one without any public interest: but it is hard, after trying to do one's work honestly, to be accused of petty meanness. I would not have troubled you, had the Editor of *Truth* published even the substance of the disclaimer I sent him, instead of absolutely distorting it.

Yours, &c.,
H. Trueman Wood,
Secretary to the British Committee.

Society of Arts, John Street, Adelphi, London, W.C.,
26th March, 1890.

THE RATING OF MACHINERY.

To the Editor of "Industries."

Sir,—When last year a Bill was introduced in the House of Commons dealing with the much-vexed question of the rating of machinery, the large amount of interest which the members felt in the question was exemplified by the House being counted out. I write to you now in order that attention may be directed to the fact that the Bill for the Exemption of Machinery from Rating has been ordered for second reading on the 16th April, and it is to be hoped that manufacturing constituencies will make a point of requesting their representatives to assist at least in keeping a House.

To say that we live in a time of keen competition with foreign countries appears somewhat like announcing that Queen Anne is dead; but at the same time the former fact has evidently not impressed itself upon our legislators with very great force, or a quorum would have turned up last year. The question is not one of party politics, but one which affects us as an industrial community. It has been agitated for years and years, and it is now high time that it should be seriously considered by Parliament. Cheapness of production is in most cases an essential factor in our maintaining our commercial position, and rating the machinery used in production enhances the cost. It follows, therefore, that the system is injurious to trade.

Yours, &c.,
F. B.

London, 24th March, 1890.

THE INSTITUTION OF NAVAL ARCHITECTS.

The annual meeting of this Institution was opened on Wednesday, the 26th inst., at the rooms of the Society of Arts, John Street, Adelphi, London.

In moving the adoption of the report, which showed that the success of the Institution was maintained, the President, Lord Ravensworth, spoke of their losses by death during the past year, and referred more particularly to the late Sir Spencer Robinson and Mr. Thomas Gray. He went on to say that the year had been marked by great activity in the shipbuilding trades, great production, and moderate profits. There had been turned out 1,286,000 tons of shipping in the course of the year, of the value of £20,000,000, and the remarkable difference between the shipbuilding of last year and that of 1883—another busy year—was, that while in 1883 the ships built were only 15 per cent. of steel, last year 92 per cent. of the tonnage was built of steel and only 8 of iron. Moreover, the ships built last year were for regular lines and special trades, and their construction showed that strength and great steam power were characteristics of the merchant vessels of the present day. The increase of price of material and labour had caused fresh orders to become scarce. Indeed, there were scarcely any new orders at all, and the work now in the yards of the country was from last year's orders, which had kept the yards busy in January and February of this year. He expressed the hope that the workers and the employers would find some means of abolishing strikes, which broke down the confidence of employers, and this lack of confidence would cause workers to lose the advantage of constant wages. As to the Load Line Bill, he expressed his strong objection to legislation of a compulsory character. Such legislation was not required for the best shipowners, and the owners of other than the best ships could evade such laws; and, moreover, such laws could not be enforced against foreign ships.

The first paper which was read was by Mr. W. H. White, Director of Naval Construction, on "The Recent Naval Manœuvres." Mr. White, at the request of the First Lord of the Admiralty, went afloat last August and remained with the fleet during the manœuvres, and his paper therefore embodied the results of his own observations. He divided his subject into four parts:—(1) The influence of size and weight upon the seagoing qualities of ships; (2) the influence of freeboard, height of guns above water, and disposition of armament upon fighting qualities at sea; (3) sea speeds and measured-mile speeds of warships; and (4) special characteristics of warship propulsion. As regards the first head he said that the possibility of any ship continuing to fight and maintaining speed at sea depends largely upon her length and size, as well as upon her freeboard and the disposition of her armament. The first-class passenger steamers of the first rank greatly exceed, in displacement as well as length, the largest cruisers yet constructed. On this account it is unreasonable to expect that war cruisers can catch vessels like the "City of Paris," or "Teutonic," or "Umbria" at sea. Moreover, they are designed for entirely different services, and cannot well be compared. It has been proposed that war cruisers should be built equalling these "greyhounds" in speed and coal endurance, but surpassing them in armament and protection. To do this must involve still greater displacement and cost; and one may well hesitate in embarking on such a course so long as England possesses not merely a vast superiority in swift merchant steamers available as auxiliaries to the regular fleet, but also larger war cruisers than are to be found in foreign navies. In the Royal Navy there is not merely room, but a positive necessity, for vessels of widely differing sizes and types. Furthermore, there is a consensus of opinion that no small proportion of our total force, particularly in the cruiser classes, should be of moderate size and cost, in order that a considerable number of vessels may be available without an inordinate outlay. For sea work and the line of battle, however, there seems good reason for the opinion generally held in the naval service that ships of large size are absolutely necessary.

Under the second head of his paper Mr. White drew a comparison between the behaviour of ships of different types in varying conditions of weather, and pointed out the advantages and disadvantages of each, with special reference to their fighting efficiency. He took occasion to deny that there is any foundation for certain strictures which had been passed on the accommodation, ventilation, and living quarters on the ships of the "Admiral" and "Medea" classes. He mentioned that the Admiralty have decided, largely as the result of experience gained with cruisers during the manœuvres, to construct a considerable number of the second-class cruisers building under the Naval Defence Act with flush upper decks. This entails increase in size and cost, but will add to the seagoing and fighting qualities.

He then passed on to the third section of his paper—Sea speeds and measured-mile speeds of warships. These are designedly and avowedly made under the best possible conditions—engines and boilers in perfect order, the best coal, skilled stokers, calm weather, smooth water, and clean, freshly-painted bottoms. Only under these conditions can such trials be of service either for purposes of comparing ship with ship, or of yielding information which will be of value in future designs. For warships of all nations, moreover, this system of trial is established, and the recorded speeds are measured-mile speeds. In recent years Admiralty practice in the trials of Her Majesty's ships has been varied considerably, and always in the direction of greater stringency. It is doubtful if equally severe trials are made with the ships of any other navy. Official records of speeds for Her Majesty's ships in the Navy Estimates and elsewhere have also for some years past given both the natural and the forced draught speeds. In the Navy List only the forced draught power is given. Passing from these standard trial conditions to the conditions of actual service, everyone having any acquaintance with the subject is well aware that there must be a considerable reduction made both in the powers developed and the speeds obtained. Engines and boilers will not remain in perfect order; coal is often of indifferent quality; stokers are not always equally efficient, nor can one expect from them over long distances work equal to that performed over a trial of a few hours; the bottoms of ships do not long remain clean, and it is rarely calm weather at sea. All these variable conditions affect actual performances at sea, and it is practically impossible to lay down any scale of even approximate reduction in order to connect trial speeds with sea speeds for all classes and sizes of ships.

For years past, however, in Admiralty practice, a rough rule has been followed. It assumes that the maximum power likely to be developed continuously, for steaming at sea over long periods, will be not more than two-thirds, or less than one-half of the natural draught power developed on the contractor's trial. And further, recognising the impossibility of making any constant allowance for fouling of bottoms, roughness of sea, or force and direction of wind, it has been the practice simply to record the speed which the reduced power would give if the vessel had a clean bottom and was steaming in smooth water. In the Navy Estimates for 1890-91 particulars are given for all the ships now building, not merely of the contractor's trial speeds and powers, but the approximate speeds and powers for continuous steaming under the assumed conditions of clean bottoms and smooth water. A new regulation, made about three years ago, has given practical tests to this approximate rule for the ratio of power developed when steaming for long periods to the power developed on the contractor's trial. The results have been eminently satisfactory, much more than fulfilling the office assumption.

This "Medea" class of ship has been made the subject of considerable criticism, more especially on the ground that the intended speed has not been realised. The intentions of the design, however, have been realised in all respects; not merely as regards speed, but also draught, trim, stability, and structural strength. The criticism arises from a misunderstanding of facts. Prominence having been given to the forced draught, smooth water, measured-mile trial speed of 20 knots, it has been treated as if it were the sea speed. As a matter of fact, before the manœuvres began a statement was issued in which the speed of the "Medea" class for continuous steaming was estimated

Digitized by Google

at from 15½ to 15¾ knots, and experience justifies this estimate. No doubt this speed could be exceeded for short periods, just as in the chase in the North Sea the "Anson" and "Howe" steamed for six hours, and developed as much power over that period as had been developed on their contractors' natural draught trials. Further experience with all these new ships will doubtless give better results.

The introduction of forced draught has been described by a gallant officer as "an invention of the evil one"—presumably because it is associated with high temperatures. No doubt forced draught requires careful use, and may be abused. However, naval officers who have had experience with forced draught are unanimous in desiring to have in their possession the power and control which it gives, although they regard it as a provision for emergencies, and not for everyday use. To be in a position to gain a knot or two in speed each hour for only three or four hours may be of the greatest importance in critical circumstances. To deliberately sacrifice this power, while it is retained in foreign warships, would be unwise. By a circular issued rather more than a year ago, the Admiralty laid down special rules for the use of the forced draught appliances. It is ordered that "forced draught appliances are not to be used above the ½in. pressure, except in circumstances of emergency, and then only for short periods, when the maintenance of the highest possible speed for three or four hours may be of great advantage." Forced draught was not used in the Naval manœuvres. One result of the use of forced draught has been to widen the gap between sea speeds and trial speeds, and hence misunderstandings have arisen. The facts have been clearly put before the public in official documents, and British ships in the matter of recorded speeds are on the same footing as foreign warships. For all practical purposes, the natural draught trial speeds are, however, to be preferred to forced draught speeds, when comparisons are being made.

Another circumstance deserving notice is that the introduction, in recent years, of swift cruisers of small size has necessarily been accompanied by greater disparity between trial speeds in smooth water and speeds at sea. This is only another way of saying what has already been said—that the larger ship feels the check of the sea upon her speed less than the smaller ship, and may actually be capable of running down the smaller one at sea, although incapable of doing so in smooth water. This source of reduction in sea speeds is necessarily incommensurable. So is that incidental to foulness of bottom. The fact is generally admitted, but scarcely appreciated as it ought to be, and it is very important that an illustration may be given. The "Medea" was ordered to be tried, late in 1888, as a typical vessel of this class. Orders were given that her bottom should be perfectly clean and fresh painted at the time of trial. These orders were not fully carried out, and no anti-fouling composition was applied. The ship was also kept afloat for several weeks in the basin before proceeding on trial. These circumstances did not come to be known until the trials were in progress, when it became obvious that some causes of seriously increased resistance or waste of power were in operation. The trials were stopped and the vessel docked. Her bottom was found to be in a rough and dirty state, fully accounting for the unsatisfactory performance. The sister ship "Medusa" was then tried under identical conditions of draught and trim, with engines by the same firm, and with screws of the same dimensions; the only difference was that her bottom was clean. In the "Medea," 5,800 h.p. had been required to attain a speed of 16·9 knots; this power sufficed to give the "Medusa" a speed of 17·6 knots, and 5,000 h.p. gave her a speed of 17 knots. At lower speeds the difference was equally marked. It will be understood that the condition of the "Medea" was not nearly so bad as that of many ships on actual service; and the figures given furnish a strong argument in favour of the course taken by the Admiralty in giving wood and copper sheathing to a large proportion of the new cruisers now building.

Mr. White then passed on to consider the special characteristics of warship propulsion.

(*To be continued.*)

THE PHYSICAL SOCIETY.

At a meeting of this Society, held on the 21st inst., a communication was read on "The Villari Critical Points in Nickel and Iron," by Herbert Tomlinson, F.R.S. Villari has shown that the permeability of iron is increased by longitudinal traction, provided the magnetising force does not exceed a certain limit, but beyond this limit traction produces a decrease of permeability. The value of the force for which traction produces no change in the permeability is known as the Villari critical point. As far as the author is aware no previous observer has found a similar critical point for nickel, but by confining his attention to temporary magnetisation he has detected such a point with comparative ease. He has also examined the variation of the Villari critical points in iron and nickel with change of load, and has investigated the influence of permanent strain on these points. The experiments were made by the ballistic method, using wires about 400 diameters long. In each set of observations the permeability was obtained with various loads, the magnetising force being kept the same, and with each load the circuit was closed and opened until the swings on make and break were equal; this swing was taken as a measure of the induction under the given load. Several diagrams accompanied the paper, in which load and percentage change of permeability were plotted, regard being had to signs.

The author finds that for annealed unstrained iron the critical value of the force decreases as the load increases, and that the Villari point is much lower for temporary than for total magnetisation. With a load of 4·7 kilogs. on a 1 mm. wire the value of the force giving the temporary point was 2·8 C.G.S. units. He also found that for a given magnetising force there are generally two loads which have no effect on the temporary magnetisation.

With unstrained nickel the critical value of the force is much greater than in iron, being about 114 C.G.S. units for a load of 10 kilogs. on a wire 0·8 mm. diameter and 67 for a load of 6·6 kilogs. For a force of 21 units no critical point exists. Experiments on a permanently strained iron wire show that for magnetising forces ranging from 0·03 to 0·3 there is no critical point, and all the resulting curves are identical. There is, however, considerable difference in the observations taken during loading and those taken on unloading. For greater magnetising forces the curves cease to be identical, and the maximum increase of permeability becomes less and less until for a certain force the curves begin to cut the load line. As the force increases beyond this value the point of cutting approaches the origin, and the curves begin to cut the load line in two points. Further increase of force to 3 C.G.S. units causes the first point to disappear and the second point to recede from the origin. Finally, with sufficiently high magnetising forces, the second point cannot be reached before the wire breaks, and the curve lies entirely below the load line.

With nickel the curves for very minute forces, like those of iron, are exactly the same for the different values of the force, but they lie below the load line—*i.e.*, the permeability is diminished by loading. There is no difference, however, in the loading and unloading curves. Beyond a certain value of the force the identity of the curves ceases, and that part of the curve near the origin bulges towards the load line. For a force a little over 21 C.G.S. units the permeability begins to increase with the load, and the curve cuts the line in one point, which recedes from the origin as the force increases.

Mr. Shelford Bidwell said that Professor J. J. Thomson, reasoning from the change of length by magnetisation, had predicted a Villari point in cobalt when compressed, and this was verified experimentally. On applying similar reasoning to nickel he (the speaker) did not expect to find a Villari point, and both Sir W. Thomson and Professor Ewing had searched in vain for one. In some experiments, not yet completed, he had examined the behaviour of nickel, both loaded and unloaded, when subjected to various magnetising forces. These show that the metal always contracts when magnetised. For no load the contraction at first increases with the magnetising force, but attains a maximum. With a moderate load the contraction is less for small forces, but for larger forces becomes equal and then exceeds the contraction of the unloaded wire. For great loads the contraction is less than when unloaded for all values of the force.

A paper "On Bertrand's Idiocyclophanous Prism" was then read by Professor S. P. Thompson, D.Sc. This hitherto undescribed prism is a total-reflection one made of calc spar, which shows to the naked eye the rings and crosses such as are seen when a slice of spar is examined by convergent light in a polariscope. The spar is cut so that the light, after the first reflection, passes along the optic axis, and, after a second reflection, emerges parallel to the incident light. The rings and brushes are present in pairs, but two pairs may be seen by tilting the prism to one side or the other. This was demonstrated before the Society. Professor Thompson also exhibited a similar prism cut from quartz. Owing to the feeble double-refracting power of the substance no conspicuous rings could be seen, but when examined by the lantern traces of such rings were visible.

The next paper was "On the Shape of Movable Coils Used in Electrical Measuring Instruments," by Mr. T. Mather. The object of this note is to determine the best shape of the horizontal section of swinging coils such as are used in D'Arsonval galvanometers, electrodynamometers, wattmeters, &c. Assuming constant period and constant moment of inertia about the axis of rotation, it is shown that for zero instruments the best shape of the section is two circles tangential to the direction of the deflecting field at the point about which the coil turns. A table accompanied the paper, in which various forms of section were given, together with their relative deflecting moments per unit moment of inertia, the coils being taken of equal lengths and the current density constant. From this table it appears that ordinary D'Arsonval coils only give about 45 per cent. of the maximum deflecting moment, and ordinary Siemens dynamometers from 40 to 53 per cent. The various assumptions made in the paper are shown to be justifiable in commercial instruments, and the modifications necessary in special cases are pointed out.

Mr. C. V. Boys said he had, when working at his radiomicrometer, arrived at a shape similar to that recommended in the paper. He also noticed a peculiar relation true for all shapes where the length parallel to the axis of rotation is great compared with the breadth. Suppose a coil of any dimensions, then another coil of half the breadth and double the length, and cross section will be dynamically, electrically, and magnetically the same as the original; for the moment of inertia, the electric resistance, and the enclosed magnetic field are equal. The above relation is also true when the breadth is not small, if the cross pieces be thickened near the axis so as to make their moment of inertia proportional to their length. He inquired whether the author had considered the subject of grading movable coils; he himself was of opinion that, unlike fixed galvanometer coils, the wire near the axis should be thicker than that further away.

The President remarked that in 1881 Professor Perry and himself exhibited a wattmeter at the Society of Arts, whose movable coil somewhat resembled one of those in the paper, which gave a deflecting moment of 95 per cent. of the maximum. In designing the instrument they had felt that the ordinary method of using a comparatively large swinging coil was not the best, and this led them to the shape adopted.

MESSRS. CHARLESWORTH, HALL, & CO.'S DYNAMO.

The illustration on page 305 represents one of Messrs. Charlesworth, Hall, & Co.'s dynamos, which has been specially designed for driving from a gas engine. These machines are carefully designed mechanically as well as electrically, and the lubricating arrangements are very convenient and perfect. Each bearing is fitted with a special sight-feed lubricator, which is so arranged that the feed, when once adjusted, can be turned on or off without fresh adjustment, and can be increased or decreased at any time when found necessary. Each bearing is also fitted with two simple siphon lubricators, which are intended to be used if any of the bearings should become heated. The waste oil from the bearings is caught in the enlarged ends of the pedestals, and runs from these into the insides of the pedestals and down into the standards carrying them, and can be drawn out as required. These arrangements keep the machine entirely free from oil except where it is required. The bed-plate has been extended to support the extra weight of the fly wheel, which is 30in. diameter and weighs about 6 cwt. After being turned all over, this has a wrought hoop, previously bored, shrunk on and then turned up. The shaft is of hard steel, and is 2in. diameter in the bearings at the pulley end, and 1⅞in. at the other end. The bearings are of aluminium bronze, each 8in. long. The pulley is 13in. diameter, and carries an 8in. belt. The bed-plate is of massive construction and well ribbed to withstand rough usage in transit and fixing.

The magnet cores are of soft charcoal iron fitted into holes bored through the bed-plate and secured in their places by screws. The pole pieces are in one forging with the magnet cores, and are bored from the pedestals to receive the armature, which is placed exactly in the centre. The armature frame is of strong aluminium brass, and the core, which is 12in. diameter, is built up of soft charcoal iron discs insulated from each other, and has an area of 40·5 square inches. The commutator bush is a steel casting with wrought-iron nut and washer, and is 6½in. diameter; it has 80 hard drawn copper bars, 1in. deep, and is insulated entirely with mica. The armature is wound with 200 convolutions of one No. 8 B.W.G., and has a resistance of ·045 ohm. The magnet is shunt wound only (for charging accumulators), and each leg is wound with ten layers of No. 14's and sixteen layers of No. 15's, and has a total resistance of 31·6 ohms. There are two brushes on each side of the commutator, each of which can be adjusted independently of the other. These machines work without any sparking with the full load; when working lamps the normal load is 150 amperes and 100 volts at 670 revolutions per minute, and 150 amperes and 140 volts at 820 revolutions when charging accumulators.

Digitized by Google

The electrical efficiency when working lamps as above is—

Loss in armature ... 6·2 p.c.
„ magnet..... 1·94 p.c.

Total loss ... 8·14 p.c, *i.e.*, 91·86 p.c. efficiency.

or when charging accumulators with 140 volts—

Loss in armature = 4·474 p.c.
„ magnet = 2·741 p.c.

Total loss = 7·215 p.c., *i.e.*, 92·785 p.c. efficiency.

The above machines are 5ft. long and 2ft. 8in. wide, and 3ft. 6in. high over all.

THE INSTITUTION OF ELECTRICAL ENGINEERS.

THE meeting of this Institution on the 20th inst. was occupied with the continuation of the discussion on Mr. Swinburne's paper, "The Theory of Armature Reaction in Dynamos and Motors," and on Mr. Esson's paper, "Some Points in Dynamo and Motor Design."

Mr. A. P. Trotter disagreed with Mr. Esson's statement as to the inutility of, and the difficulties attending, calculations of the stray field, and said that since Professor Forbes gave his three lemmas in 1886 the work has been comparatively simple, and constituted in one case a part of drawing office routine. This predetermination is most important when any departure from ordinary designs is made, for in such cases one cannot be guided by previous experiment. Mr. Trotter also exhibited

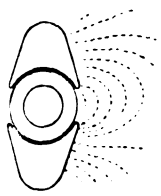

FIG. 1.

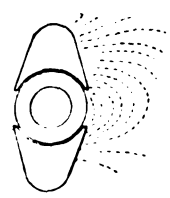

FIG. 2.

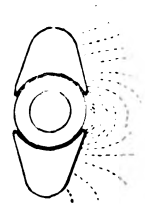

FIG. 3.

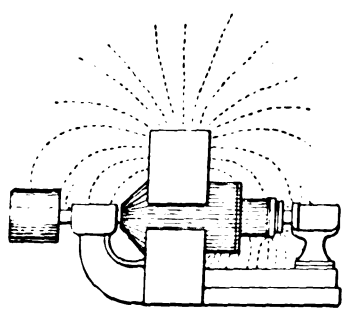

FIG. 4.

the accompanying diagrams of field distribution made from actual dynamos. A sheet of paper was cut to fit the machine and held in the plane in which the lines were to be plotted. A needle on a pivot, with an india-rubber stamp stuck on, was held in the field, and the position recorded by stamping an impression. Series of impressions represent lines of induction. On one of these diagrams the distorting effect of a large armature current can be easily seen.

Mr. Vignoles confirmed Mr. Trotter's remarks about the calculation of waste field by Mr. Ravenshaw.

Mr. S. Joyce, in speaking of Mr. Esson's rule for rise of temperature, said such rules could only give the temperature at the surface, and not that of the interior, which was probably much greater. As the difference in temperature between the inside and outside of the winding varies as the square of the depth, this difference may become excessive in large machines. The expression for the difference, on the assumption that the inside and outside surface are parallel planes, was given as $hD^2/2K$, where h = C.G.S. heat units generated per cubic centimetre, D = depth of winding, and K its thermal conductivity. For cylindrical surfaces of ordinary dimensions the difference is about 3 per cent. less. The quantity K may be calculated from the equation $K = Zd/2\delta$, where Z is the thermal conductivity of the insulating material, d the diameter of the covered wire, and δ the radial depth of insulation.

Mr. J. D. F. Andrews thought the heating of armature conductors could be got over in a simple way by paring down the pole corners so that the conductors came into and out of the field more gradually.

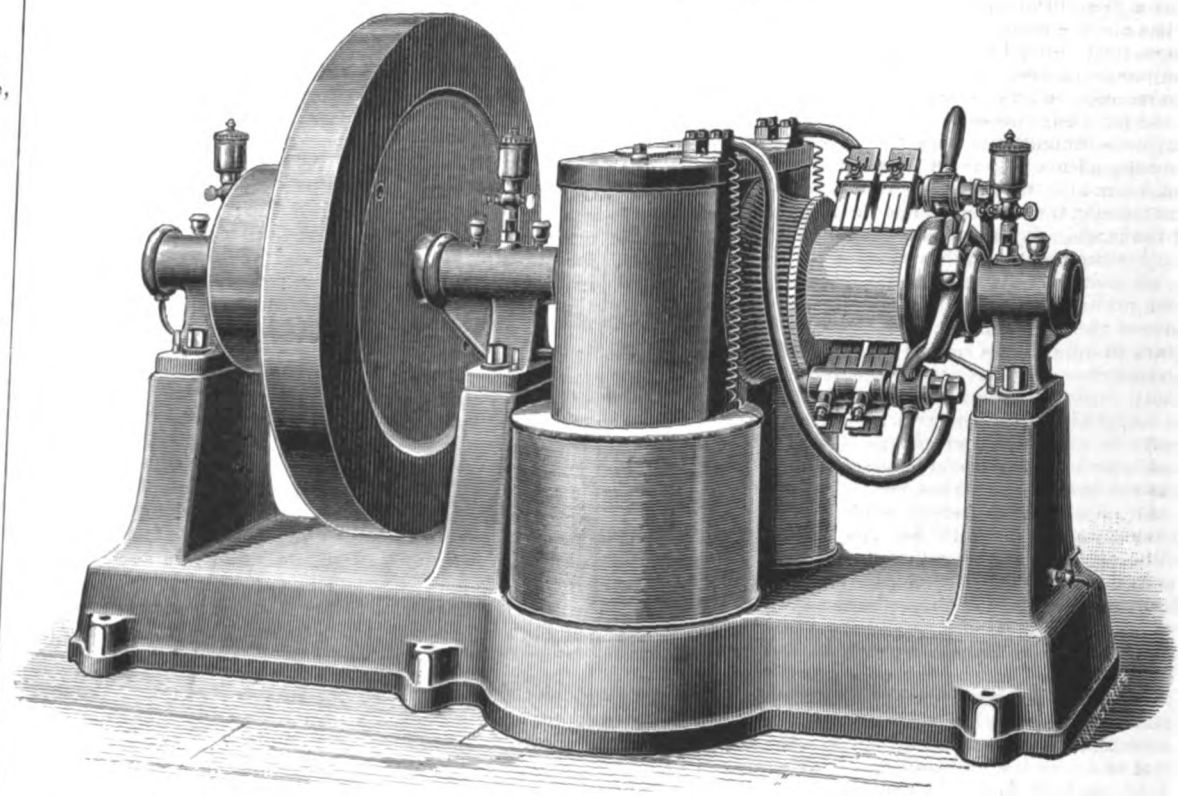
Mr. Stuart A. Russell, in referring to Mr. Esson's curve for maximum output, said he believed this was obtained on the assumption that the depth of winding inside the armature was equal to the depth outside. If the difference between these depths be taken into account, then in ordinary cylinder armatures, instead of the core being about 4 times the depth of the winding, it becomes $5\frac{1}{4}$ times. Concerning the design of motors, the speaker said he agreed with the authors of the papers, but the startling nature of the curves shown by Professor Ayrton had led him to make experiments on the subject. From them he concluded that the e.m.f. of a motor may be made greater than that of a dynamo by short-circuiting a number of sections, thereby increasing the armature induction, but that no advantage is gained, because the result is just the same whether the greater induction is produced by field magnet windings or by coils short circuited by the armature brushes. His experience with motors having thick brushes did not agree with Mr. Snell's, for in tramcar work he (the speaker) got the best results with brushes of ordinary thickness.

Mr. Wyles said no doubt need exist as to the possibility of making smooth commutator machines for high voltages, and that the difficulties experienced arose from the great differences in the insulation of similar machines. The insulation of some may be excellent, whereas that of others wound with equal care is comparatively bad. These differences are met with in machines of e.m.f.'s as low as 200 volts.

Mr. Geipel asked whether cross-induction could not be reduced by nicking the pole pieces in Mr. Swinburne's paper until they separated into two parts, and by laminating the magnets in a direction perpendicular to that of the cross lines. Referring to Mr. Esson's temperature limit of 75° C., he inquired whether any modification would be made for machines intended for tropical climates.

Dr. S. P. Thompson, in a communication read by Mr. Kapp, said that a good approximation to the back ampere turns was got by multiplying the number of conductors between the pole corners by half the armature current, and that he agreed with Mr. Swinburne as to the usual position of the brushes. He complained of Mr. Swinburne's use of "ergs" in measuring magnetic potential, and asked why, in naming the pole corners, he had reversed the ordinary usage. He also inquired why Mr. Esson took the load carried by armatures as proportional to the depth for armature core. Speaking of "leakage coefficients," he pointed out that this is not constant even for machines of the same type, but is less for the larger machines. As regards smooth commutator machines for high voltages, he said Messrs. Paterson & Cooper had made such machines successfully for some time, and that in Ball's so-called "unipolar dynamo" was an instance of a smooth commutator machine working 80 arcs in series.

Mr. MacWhirter objected to Mr. Swinburne's use of the symbol Ω for magnetic potential, for this is the recognised symbol for megohm. Speaking of the magnetic pull on armatures of single magnet machines, he said his firm found the method of placing the armature eccentrically very effective.



The President expressed his great appreciation of both papers under discussion, but, owing to the lateness of the hour, would only criticise a few points in Mr. Swinburne's. The rule given for lead of brushes seemed to him hardly correct, for in machines with which he was acquainted the lead was always less than half the angle between the pole corners. There were two points to which he wished to direct Mr. Swinburne's attention, viz., the effect of having a great or a small number of commutator bars, and of thick or thin brushes. Speaking of the term "magnetic resistance," he said there were two reasons why he did not use it. First, the generally accepted idea of "resistance" was such that $(flux)^2 \times resistance$ was a rate of doing work; so-called "magnetic resistance" did not satisfy this condition. Secondly, "coefficients of resistance" are generally constant, and express properties of the material or medium. "Magnetic resistance," however, is by no means constant, and he thought its use open to the same objections as "resistance of an electric arc," an expression which was very misleading.

Mr. Swinburne, in reply, said the main subject of his paper had not been discussed. Its object was to show how to obtain an expression for the lead of the brushes in terms of the polar angle, and thus determine the back induction before the machine was made. This was of much greater importance in regard to large machines. The greater part of his paper referred to such machines. Professor Ayrton, he said, had accused him of using "magnetic potential" where "difference of magnetic potential" was meant. This he denied, and pointed out that he had been careful to speak of difference of magnetic potential. Referring to "magnetic lag," he said the time lag discovered by Professor Ewing had no connection with the once supposed lag to which the lead of the brushes was wrongly attributed. As regards the results of experiments on machines run as generators and motors by Professor Ayrton, he pointed out that in those experiments where the e.m.f. became negative with a large armature current, the generator became a motor and the brushes were then in the wrong position. He also contended that in all cases where the e.m.f. of a motor increased with increase of armature current, the brushes were not in the proper position. He believed Mr. Esson's results on the Bürgin machine was due to the same cause, for in this machine, unless made specially as a motor, the brushes could not be put back far enough

AN IMPROVED DYNAMO.

to run sparklessly. Probably Mr. Esson had been misled by not being aware that the commutator connections are skewed. Replying to the criticisms on his use of "ergs" in measuring magnetic potential, he said Sir W. Thomson was the first to introduce it, and as it had been used by Maxwell and others, he thought he might use it too. His objections to "magnetic resistance" were, first, that the term has no definite meaning; secondly, that the analogy whence it is derived is wrong; and thirdly, if used it is liable to lead to error, as has already been the case with regard to transformers. Magnetism, he said, was analogous to electrostatics, and permeability to specific inductive capacity—not to conductivity, as the advocates of magnetic resistance would have us suppose. In his opinion, four-pole drum machines would be used in the future for large power outputs. He was sorry to learn that Mr. Mordey had not been able to make a shunt Brush machine work successfully, for he himself had done so, and the inventor of the machine approved of the arrangement. As regards the position of the brushes relative to the pole corners, he pointed out that Dr. Thompson's observations agreed with his own, and not with those of the President. In answer to the President's inquiry why he did not integrate to infinity in a certain case, he said the integration had only been given as a rough approximation near enough to the truth to show that a comparatively weak field is required to reverse the current in the armature sections of direct current machines. If alternating machines were under consideration the treatment of the subject would be different.

Mr. Esson, in his reply, said Mr. Kapp's method of overcoming side pull had the disadvantage of not allowing the coils to be slipped over the poles, and that, even if adopted, the distribution of the field was not the same near the top brushes as near the bottom ones. He could not understand how Mr. Kapp saw any "dodge" in designing armatures to give large outputs, for the magnets were designed in accordance with the armatures with which they had to work. Neither could he understand Mr. Ravenshaw's remarks about the loading of armatures. In his opinion, the machines of a set could not be all in the same condition as regards balance of field, and he thought all Mr. Ravenshaw's dynamos were underloaded. He was glad to see that Professor Ayrton's remarks respecting the number of ampere turns required for compounding agreed with his own statement on the subject. Referring to Mr. Crompton's armature conductors, he said he had used stranded wire for the same purpose, but the section of his subdivided conductor was round, and not rectangular as in Mr. Crompton's. He would have been glad to learn something about the collection of large currents, for this seemed to be one of the most difficult problems at present. On the subject of motor construction Mr. Esson said Professor Ayrton's curves showed that it was difficult to prove either point conclusively.

PRACTICAL WORKING OF THE ELECTRICAL SUBWAYS IN NEW YORK.

(*From our New York Correspondent.*)

(*Continued from page* 283.)

Concerning the question of the relative durability of rubber compound and fibrous cables, sufficient time has not elapsed to enable one to arrive at a definite judgment. Many circuits have been running continuously for over nine months, and in some instances for over one year, without a defect of any kind, electrical or mechanical, having occurred, and the slighter defects that have occurred on other circuits have as yet been so few in either type of cable as not to certainly show any marked superiority of one type over another. Specimens of cable that have been examined, after nine or twelve months' service, show no physical or electrical signs of deterioration of the insulation. As regards the question as to which kind of cable will best withstand the heat from steam pipes adjacent to the subways, it would appear thus far that the lead-covered fibrous cable is superior to the homogeneous cable not lead-covered. Lead-covered rubber compound cables have not as yet been tried in the heated districts.

There are no concentric cables in these subways. The mains of multiple arc circuits are operated in separate lead covers in the same duct. It is contemplated by some of the companies to use one lead cover for such circuits hereafter. One objection to the use of concentric cables is the difficulty in making joints, where frequent connections for distribution are required.

One fibrous insulated cable, having eight conductors under one lead cover, was placed in the subways, but has not been operated as yet, trouble having been found in making perfect joints. It seems to be the general opinion that the use of multiple cables is not advisable in electric lighting.

On the subject of loss due to increased electrostatic capacity, or to increased self-induction of conductors in the subways, no perceptible difference in the operation of the circuits as compared with similar circuits overhead is noticeable. In wet, stormy weather, a decided improvement is observable—in fact, the condition of the weather does not affect subway circuits. This will be readily understood when it is stated that a recent test, made during the prevalence of a drenching rainstorm, of an arc circuit in the subways, four miles in length, showed an insulation resistance of 2,400 megohms per mile. The lamp connections were disconnected from the cable proper during the tests, so that the entire cable was under cover except at the pole.

Several forms of joints are used on the electric light cables in subways, among them one known as the "rubber" joint, sometimes termed the "half-marine" joint, made as follows:—First, the lead covering is removed for three inches from the end of the conductor. An inch of the insulation is then removed from the ends of the conductor; the ends of the conductor are then "sweated" together. Generally a split copper sleeve is placed over the ends. When a T-joint is to be made a T-sleeve is used. This facilitates the making of the joint by dispensing with filing the ends of the conductor and then wrapping them with small wire. No acid is used in the making of the joint. Resin is commonly used. After the wire has been spliced, the insulation is scarfed for about three-quarters of an inch, when a layer of pure rubber strip is wrapped around the wire spirally back and forth about three times, and each time the rubber is brought further up the scarfed insulation. A few layers of white rubber strip are then wound above the pure rubber strip, and after that a layer or two of pink rubber strip. A layer of fibrous rubber tape is then put on over all. Between each layer of rubber strip a small quantity of rubber solution is put on to make the rubber adhesive and practically homogeneous. A lead sleeve is then placed over the joint and wiped on to the lead covering. This joint can be made in about twenty minutes, exclusive of time taken in wiping the lead sleeve. This joint is used altogether on the "Bishop" and the "safety" cables; also, occasionally, on the "Waring" and "Cobb" cables. But as a rule the "Cobb" people make a special joint somewhat as follows: The ends of the conductors are spliced in the usual way, a hard rubber ferrule having first been placed over one end of the conductor and a brass ferrule over the other conductor, above the insulation. A machine, like a double vice, is then placed over the lead covering of the cable and made fast thereto. A tightening device next draws the ends of the vulcanite together, taking up slack in the cable. The vulcanite sleeve or ferrule is then welded by heat to the vulcanite tube, after which the brass ferrule is drawn over the tube. A mould is then placed around the joint, into which molten lead is poured, thus casting a solid lead sleeve. This is quickly cooled by the application to the mould of cold water. The mould is then removed and the joint is complete. This form of joint has been found satisfactory, and can be made in less time than a half-marine joint. The joint chiefly used on the "Waring" cable is made differently from either of the foregoing. After the conductor has been spliced as usual, and the lead covering has been cut back from the insulation, a few turns of tape is passed around the splice. A leaden sleeve is then put on over this and wiped firmly to the lead cover of the cable. When this has been done a couple of small holes are punctured in the lead sleeve, through which a boiling insulating compound, used in the manufacture of the cable, is poured, filling up the sleeve completely, after which the holes are closed by solder. These joints have been found to give excellent service on this form of cable. The time taken in making this joint is about thirty minutes.

(*To be continued.*)

ILLUMINATING WATER GAS.

The severe competition introduced by the adoption of electric lighting and other systems of public and private illuminating within the last few years has roused the gas engineers to seek improvements in gas manufacture with the view of maintaining the industry in its present position. It used to be frequently stated that the methods employed for the manufacture of coal gas had not differed essentially from those used in the earlier days of the industry, either in the form of apparatus and plant or in the distillation of the coal and the purification, storage, and distribution of the gas. In recent years, however, the gas engineer has effected important economies in the construction and use of his plant, and has called to his aid the knowledge which has been accumulated by the chemist, until at the present time we have many novel and ingenious processes emerging from their period of experimental trial which mark important departures from the primitive forms of manufacture. In addition to the competition of rival lighting systems, the increase in the price of coal and labour has contributed to this revolution in the industry, and many of the gas companies in England feel that it is absolutely necessary that considerable alterations in their old plant must be undertaken before long in order that they may, while complying with the conditions of their respective Acts with regard to quality and illuminating power of their product, give a fair return on the capital invested in their enterprise. The Parliamentary returns for 1888 show that the gas industry in the United Kingdom employed upwards of £62,000,000 of capital, and that the gas produced amounted to the large total of nearly 100,000,000,000 cubic feet obtained by carbonising 10,000,000 tons of coal. With such large figures as these statistics show that it is not surprising that thought is being directed towards effecting economies and improvements in the industry. Many of these departures have already been noticed in *Industries*, and those of our readers who are interested in the subject will easily call to mind the improvements effected by the Dinsmore and Loumis processes, by the recovery of sulphur and economies in manufacture effected by the use of the Claus kiln at Belfast and elsewhere, and the improvements in purification and increase in illuminating power by the use of oxygen gas at Ramsgate. Time alone can decide between these and other modifications of the original plan for the manufacture of coal gas and other processes which are based on entirely different systems. We illustrate on page 307 an experimental plant which has been erected at Knightsbridge and at work for some months for the manufacture of illuminating water gas on the Van Steenbergh system. This system has been in use for many years in America, where it and other similar processes have been employed in new cities which were not handicapped by having coal gas plant already erected. The arguments for and against the use of water gas as a source of heat have so recently been brought to the notice of the public that it is unnecessary to repeat them here. It must, however, be remembered that water gas, when used for illuminating purposes, requires some such appliance as the comb commonly used, or some other material which is heated to whiteness by the flame, such as is employed in the Welsbach system of incandescent gas lighting. Although these systems, based on the heat-giving properties of the gas being utilised for raising the temperature of some solid material to incandescence, have many advantages, yet the necessity of a burner of delicate construction and of special form undoubtedly militates against their rapid introduction.

Illuminating water gas as used in America, and of which the Van Steenbergh gas may be taken as a type, is water gas which has been charged with hydrocarbons which render it a fixed illuminant similar to coal gas, to which it agrees very closely in chemical composition. The gas manufactured by this system can be distributed and burnt in the same way as coal gas itself, and is characterised by giving a white light of great brilliancy and having an illuminating power equal to that obtained from cannel coal, or some 6 or 8 candles higher than that of ordinary coal gas. Although of the same candle-power as cannel gas, it differs from it in being of more uniform composition and burns with a flame which is free from smoke. Such carburetted water gas is now in use in one-third of the towns lighted by gas in America, and the gas appears to give as much satisfaction to the consumers as ordinary coal gas. The Van Steenbergh apparatus possesses the advantage over other similar processes in use, in its simplicity of construction, as only one generator is employed for producing the water gas and giving it an illuminating power. In other systems, the water gas is usually generated in one vessel, and the hydrocarbon oil volatilised and decomposed in a second, and the two gases thus separately produced lead into a mixing vessel where the gas is finally fixed for the holder. Some systems use only two vessels, the two gases being produced in one generator and rendered a permanent mixture in a second. The plant employed at Knightsbridge, as shown in our illustrations, consists of a tall cylindrical iron generator lined with fire brick, and in it the whole of the manufacture is conducted. It is half filled in the first instance with anthracite or coke, which is heated to whiteness by a powerful air blast introduced at the bottom of the generator. The producer gas and its waste heat can be utilised by leading the gases formed at this stage of the operations by a special tube at the top of the generator (this tube is not fixed to the small plant which we illustrate) to the furnace at the right which heats the boilers used for producing the steam required in the second operation. The time occupied in blowing and raising the fuel to the necessary temperature is roughly equal to that required for making the gas in the second operation. In one run, details of

which we give, it will be seen that when a quantity of gas equal to 8,400 cubic feet was made, the time occupied in blowing was 58 minutes, and in gas making 48 minutes. This second operation consists in introducing below the grate bars at the bottom of the generator a continuous jet of steam superheated by passing through a coil heated by a small furnace shown on the left in our illustration (Fig. 1). The mixture of hydrogen and carbonic oxide formed in this manner rises in the generator and meets in its passage upwards with the products of dissociation of liquid oil or naphtha which is injected into the generator near the top of the column of incandescent coke through tubes in the sides of the generator. The illuminating hydrocarbons produced from the oil here mix with the hydrogen and carbon-monoxide of the water gas produced below in the same apparatus; the mixed and fixed gas then passes out of the top of the generator by a pipe to the holder, washers, scrubbers, and purifiers, and is ready for consumption.

The inventor claims for this process a product of uniform quality and considerable economy in labour and fuel. The naphtha employed consists of the first runnings obtained in the distillation of American petroleum, and is of very little commercial value. There is only a limited demand for it in this country and America, and as it has been hitherto looked upon as a kind of waste product a new application for it should be received with satisfaction. The supply of it is practically unlimited, and the recent improvements in tank steamers for the transit of oil in bulk will facilitate its export to this country at a cheap rate. In America the fuel employed has been the harder kinds of Pennsylvanian anthracite, but the Welsh anthracite also gives highly satisfactory results. The annexed table shows that very good results are obtained by the use of foundry coke, and although gas coke does not apparently give so good a yield, its cost is much less, and as it will be probably in connection with existing gasworks that the new plant will be erected in this country gas coke will eventually be the fuel finally selected.

The experimental work at Knightsbridge has been under the supervision of Professor Lewes, of Greenwich, and he has devoted much attention to the composition of the gas obtained by the use of different qualities of fuel and oil. Tables I. and II. give full details of experimental runs with the Knightsbridge apparatus, and show the yield and quality of gas produced. From them it will be seen that the gas has an illuminating power varying between 20·5 and 22·9 candles due to illuminants of the gas ranging between 7·49 and 11·14 per cent. We give in Table III. for comparison Dr. Letheby's analyses of London gas, which, although made many years ago, represent the quality of common and cannel gas. At that time the common gas had an illuminating power of only 14 candles, and as the limit has been raised to 16 candles, it is now customary in most works to carbonise a certain amount of cannel coal in order to improve its illuminating power. It will be noticed that, although the Van Steenbergh gas contains a percentage of illuminants intermediate between that of common and cannel gas, the illuminating power is higher than could be attributed to it from the chemical composition. The quantity of carbon-monoxide varies between 13·0 and 25·0 per cent., which, as might be expected, is much higher than that of coal gas. This means, of course, that the gas is correspondingly more poisonous, but as the finished gas has a very characteristic odour as powerful as that of coal gas itself, there is therefore not so great an objection to its employment as is the case with the odourless water gas.

Digitized by Google

Note to Table II.—The low carbonic oxide in the make from gas coke is due to the fuel never being so hot as with anthracite; and the result is an increase in the percentage of carbonic acid in the unpurified gas.

TABLE III.—*Letheby's Analysis of London Gas (for comparison).*

	14 Candle.		Cannel. 22 Candle.

Moisture	2·0	...	2·0
Nitrogen	0·5	...	0·4
	100·0		100·0

An especially noteworthy feature in the purified gas is the low percentage of sulphur compounds, and in this respect it has a very marked superiority over coal gas. The illuminating water gas also, according to Professor Lewes' report, does not lose its illuminating power on standing during cold weather more rapidly than a rich coal gas, although at present we have not seen any details of the experiments by which he has arrived at this conclusion. It is unfortunate that a gas possessing such very advantageous properties, and which can be manufactured so rapidly, should behave, at any rate, as badly as does coal gas in this respect. The loss of illuminating power, however, in this case can hardly be of the same nature as the loss of illuminating power in coal gas, as from the conditions of manufacture it seems unlikely that such complex hydrocarbons are present in the purified gas. We believe that the loss of illuminating power in coal gas is less an evil than the consequence of such loss causing an accumulation in and stoppage of the service pipes. An illuminating gas manufactured under these conditions could hardly give rise to naphthalene or hydrocarbons likely to condense to a solid or dense condition at low temperatures, so that the loss which Professor Lewes alludes to must be due to the condensation of liquid hydrocarbons or to some other cause.

Another important point to be remembered in connection with this process is the fact that there are no residual products, as practically all the fuel used is converted into gaseous bodies. We have as yet had no particulars given as to what becomes of the nitrogen present in the fuel; we assume, however, that it must exist as nitrogen in the finished product, as Professor Lewes states that no ammonia exists in the purified gas, and there would be a residual product if the gas passed through an acid purifier to remove this body. Of course, when gas coke is employed the amount of nitrogen lost is trivial, but in the event of other forms of fuel being used in the generator, the statement that there are no residuals would mean a waste of the combined nitrogen present in the fuel. The absence of all tar and condensable volatile products is certainly a very strong argument in favour of the process. Too much tar is produced for the demand, and, notwithstanding the cheapness of this residual, it apparently does not pay to convert it into dyestuffs or pharmaceutical products, these having a limiting demand. There is also a considerable saving in space occupied by the plant and in the handling and labour entailed in the removal of such residuals.

There seems no reason to doubt that this system of manufacture will give an illuminating gas at a cheaper rate than that made in the old-fashioned way in gas works, but we should not like to assign to it any position among the improved methods of gas-making. The Dinsmore system also converts hydrocarbons present in tar into permanent gas of a high illuminating value. In this method the gas manufacturer does not require to purchase any additional material, and recent statistics of this process show that a gas of 19 candle-power can be obtained at the rate of 10,000 cubic feet per ton of coal, with one-third of the carbonising plant required by the old system. This and other rival processes will naturally fight against the new comer, and it will be only possible to compare their relative merits after the apparatus has been erected on a larger scale, and a continuous make of gas extending over a long period has demonstrated its economic advantages.

Notes.

THE COTTON TRADE.

THE coal crisis of last week resulted in the lessening of the cloth production to a rather important extent, for upwards of 30,000 looms were stopped for four days. This stoppage will tend to relieve the cloth section, for stocks were beginning to show themselves in first hands. The position of weavers (employers) is still an unsatisfactory one. The margin between cotton and cloth and yarn and cloth has for some months been very narrow. Now, with a further advance in fuel, things are decidedly worse. Further, the India cloth season has been most discouraging, both to shippers and producers. Spinners are experiencing a very lean trade. At the beginning of the year the margin was profitable, but since the advance in raw American cotton from 5⅛d. to 6¼d., yarn has suffered very much. As things are to-day the difference between twist cotton and cop twist is not more than 2d. per lb. This means a definite loss on every pound turned out of the mill. One redeeming feature of the spinners' position is that most spinners are deeply bought in cotton at prices not far off ⅜d. to ½d. per lb. below the present quotations, and, in addition, spinners are well sold, some employers being fortified with contracts to the end of July or thereabouts. A few days ago Messrs. Neill Bros. reduced their American cotton estimate from the original figures of 7,600,000 bales of 480lb. each as a minimum to a little over 7,400,000 bales as this season's weight. One thing is pretty certain whatever may be the size of the crop, that the quantity of this season's growth is 3 per cent. superior to that of last year. There is less loss, and the cotton goes further in producing yarn. The proposed Bill of the operatives to amend the Factory Acts is creating great interest in employers' circles. Immediately after Easter a conference will probably take place between the United Spinners' Association and the Textile Workers' Association.

FRENCH EXHIBITION IN LONDON.

IT seems to have become a settled thing that we are to have an Exhibition at West Brompton every year. Foiled in their original intention of holding a Belgian Exhibition there this year, Colonel North, Mr. John Whitley, and Mr. Vincent Applin have turned their attention to getting over as many of the exhibits shown last year at Paris, and running a French Exhibition. They assume that it will be a great success, because only one or two per cent. of the British population went to Paris, while at least twenty per cent. desired to see the exhibits, and the latter, it is supposed, will now flock to Brompton. The Exhibition is to be opened on the 3rd May for a period of about six months, and the sections include minerals, metallurgy, machinery, railways, electricity, chemical products, and naval architecture. From the French circular sent out to probable exhibitors no indication is obtainable as to whether it is intended to entrust the electric lighting to French or to English contractors. For some reason not explained there is to be no machinery in motion.

ELECTROMOTORS IN ENGINE WORKS.

MESSRS. DENNY & CO., engineers, Dumbarton, have the tools in their pattern shop driven by a 20 h.p. electromotor. The dynamo is placed in the machine shop and driven from the ordinary shafting. From the generator to the motor in the pattern shop the current is conveyed through two cables about ⅜in. diameter. If this had not been done, a separate small engine and steam piping of great length would have been required. In the boiler shop of the same firm there is a still more interesting example of the application of electricity as a motive power. This is Rowan's patent electric boring machine, for drilling the rivet holes through boiler shells *in situ*. Anyone who has watched drilling tackle at work, especially in shipyards, must have noticed how much time was absorbed in fixing the clamp into position. Rowan's electric borer not only has a small motor to drive the drill, but holds itself up against the plate by means of a pair of powerful electromagnets. Messrs. Denny are about to put electromotors to other uses in their yard, amongst the earliest of which will be the driving of all the sewing machines in their large upholstering department, at present driven by the feet of the female operators.

MINING MACHINERY IN SOUTH AFRICA.

OUR Berlin correspondent lately wrote that some of the plant sent out by English engineers to mines in the Transvaal had proved unsatisfactory, and in an editorial letter another correspondent drew attention to similar complaints which had been made. It appears, however, that American engineers are also accused of not knowing how to transact business with South Africa. The *Engineering and Mining Journal*, of New York, asserts that American manufacturers cannot compete with our own in the market, owing to the judicious course adopted by English firms, in placing machinery, including even stamp mills, in stock at Johannesburg. The Americans will only send out to order, and raise difficulties in money matters. When they do sell, it is stated that they allow their machinery to be run by incompetent men, instead of sending some one out to see that the plant is properly set up and worked. It is stated that in consequence American machinery has got a bad name. This evidence tends to show that American competition is not to be feared at present, but it may be as well for makers to take heed of the warning as to German opposition which was given in our Berlin letter.

THE PHOTOGRAPHIC EXHIBITION AT THE CRYSTAL PALACE.

THERE are no very startling novelties on view at the yearly Exhibition of Photography which is now being held at the Crystal Palace. Several makers are trying the experiment of substituting aluminium for brass in the construction of tourist cameras, with the object of decreasing the weight of the apparatus. Messrs. Watson and Mr. Stanley are showing some new time and instantaneous shutters, which, when in action, do not cause the camera to vibrate or swing. Mr. Scorer has adopted a double eccentric motion for the purpose of bringing the lens to any part of the front board, thus doing away with the skewing of the bellows. The pictures occupy a much more important part relatively with the apparatus than they did last year. There is a tendency on the part of amateurs towards the platinotype process, but the results are on the whole decidedly indifferent; this may be accounted for by the fact that most amateurs use cheap and thinly-coated plates. The series of views of Moreton Hall, Cheshire, by Mr. Richard Keene, of Derby, are immeasurably superior to anything else in the Exhibition, both as regards choice of subject and technical treatment. The excellent contrasts and crispness and the remarkable definition in the shadows are evidently the results of over-exposure of a thickly-coated plate, such as Wratten & Wainwright's, or Edwards', together with a very slow development by sulpho-pyrogallol and carbonate of soda. We are also sorry to see that gelatino-chloride silver paper is not coming into greater use.

THE MANUFACTURE OF OZONE.

OUR German correspondent informs us that a company has been formed in Berlin for supplying the necessary plant for the conversion of oxygen into ozone on a larger scale than has hitherto been attempted, and that the idea is gaining favour in many quarters that ozone can be economically employed for many sanitary purposes. Steps are being taken for extending the operations of the company to New York and London, as they have secured the patent rights for certain improvements in the electrical production of ozone from atmospheric oxygen in most countries. The Berlin doctors have repeatedly employed ozone, with very satisfactory results, in individual cases, and recently the company above alluded to have placed on the market a so-called ozonised water which is stated to be a solution of ozone in that liquid. It is, however, well known that ozone is not very soluble in water, and that it readily undergoes decomposition, forming hydrogen peroxide and oxygen. The commercial name for this new antiseptic is "anti-bacterikon," and it possesses remarkable oxidising properties. When added to water containing any appreciable quantity of living organic matter in the dark, it at once causes a phosphorescent appearance, and the organisms are completely destroyed in a short time. Such ozonised water is stated to have a faint metallic taste, and is used for producing sterilised water, or sterilised fluids, for bacteriological research. At present the ozone is manufactured from oxygen obtained by heating pyrolusite in the old way, but, of course, with a greater demand the Brin's oxygen process could be employed. The conversion takes place in a Siemens tube, or series of Siemens tubes, which do not differ essentially from the original form of ozoniser. The electric discharge is made by a Ruhmkorf coil in the usual way, or an accumulator is employed and a mercury contact breaker. It is proposed that ozone should be produced in this manner in large manufactories, and thus contribute to their sanitary improvement. Dr. Förster, of Berlin, has recently urged the importance of endeavouring to supply a small quantity of ozone to the air of towns and other thickly populated districts, and the company believe that their system can be worked economically and at the same time produce very satisfactory results from a hygienic point of view. It has been pointed out that many epidemics—*e.g.*, influenza—appear to take place at those seasons of the year when the atmospheric ozone is at a minimum, and it is thus argued that an artificial supply of this gaseous oxidising agent would possibly prevent, and at any rate considerably modify, such outbreaks of disease.

APPLICATIONS FOR PATENTS.

(The names in italics within parentheses are those of Communicators of Inventions.)

ENGINEERING.

10th March, 1890.

3737. Bridge, J. ..... Machine for making coils or spirals.
3738. Revis & Marriott ..... Circular ribbed fabric machinery.
3740. Causer & Ward ..... Cartridge recappers.
3741. Wilkes, T. W. ..... Railway carriage door locks.
3744. Parry, R. ..... Brick machines.
3748. Pollitt & Mullin ..... Carding engines.
3754. Barrett, W. J. ..... Signalling on railways.
3755. Wotherspoon, J., Jun. ... Rolling metal bars.
3766. Jameson, J. T. ..... Slide valves.
3771. Steffenhagen, O. ..... Coupling for railway vehicles.
3772. Earsdon, J. ..... Water pressure engines.
3773. Heer, I. ..... Looms.
3774. Abel, C. D. ..... Gas motor engines (*The Gas Motoren Fabrik Deutz*).
3780. Haddan, H. J. ..... Machine for the production of motive power and cold (*Kortum*).
3785. Smith, C. ..... Stuffing boxes (*Agabeg*).
3789. Watts-Hughes & Viney Apparatus for the production of figures upon glass.
3790. Laumann, J. ..... Repeating firearms.
3791. Ashwell, J. ..... Railway chairs.
3792. Wise, W. L. ..... Knitting machine (*Dresdner Strick maschinen-fabrik Laue & Timaeus*).

11th March, 1890.

3798. Cammiss, E. ..... Brick moulds or dies.
3806. Mackay, F. N. ..... Apparatus for making ice.
3811. Bamber, H. K. ..... Hydraulic and other valves.
3815. Walker & Parker ..... Ring frames.
3817. Gedge, W. E. ..... Travelling cranes (*Wood*).
3818. Stiles & Perry ..... Signalling on railways.
3823. Arkwright, W. ..... Knitting machines.
3824. Jones, W. ..... Sewing machines.
3826. Pepper, J. E. ..... Coupling for pipes.
3828. Boult, A. J. ..... Piston packing (*Child*).
3831. Thompson, W. P. ..... Boilers (*Hörenz*).
3834. Haggard, R. A. ..... Apparatus for heating water.
3845. Barton & Higgins ..... Torpedo vessels.
3846. Lake, H. H. ..... Shrinking and fulling felt (*Husted*).
3848-9. Smith & Cooper ..... Looms.
3850. Tyler & De Vesian ..... Drilling machines.
3851. Albaret, A. B. ..... Sheaf binding mechanism.
3853. Lorimer, J. H. ..... Power transmitting devices
3854. Fowler, H. E. ..... Welding of metals.
3855. Puvrez, P. ..... Apparatus for bottling.
3858. Fowler, H. E. ..... Welding metals.

12th March, 1890.

3867. Wedgwood, A. D. ..... Machines for boring shafts.
3869. Calvert & Hunt ..... Looms.
3879. Pinkerton, W. ..... Railway points.
3881. Casey, G. ..... Carding engines.
3885. Cade, G. ..... Cock plugs.
3895. Crowley, R. J. ..... Signalling apparatus. (16th August, 1889).
3899. Patterson, E. ..... Pipe couplings.
3903. Haddan, H. J. ..... Circular loom (*Persil & Papleux*).
3912. Horn, W. W. ..... Hoisting apparatus (*Chamberlin*).
3915. Schwager, J. ..... Condensing apparatus.
3918. Justice, P. M. ..... Steam hammers (*Taylor*).
3921. Daelstaen, M. ..... Gas engines.

13th March, 1890.

3928. Boardman, J. ..... Mules and twiners.
3939. Jackson, J. P. ..... Filling and corking machines.
3940. Jackson, J. P. ..... Machines for filling bottles.
3944. Jerome & Stevens ..... Railway tie.
